

## Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

## Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

## Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter <http://books.google.com> durchsuchen.

## FIVE NEW BOOKS

### THE OPERATIONS OF SURGERY.

8th Edition. By R. P. ROWLANDS, M.S., F.R.C.S., and PHILIP TURNER, M.S., F.R.C.S. Vol. I. 435 Illustrations, 38 in Colour. 36s. Vol. II. (In Preparation.)

### MINOR SURGERY AND THE TREATMENT OF FRACTURES. 21st Edition. Revised by GWYNNE WILLIAMS, M.S., F.R.C.S. 284 Illustrations. 10s. 6d.

### MEDICAL ASPECTS OF CRIME

By W. NORWOOD EAST, M.D., F.R.C.P. 18 Illustrations. 18s.

### ELEMENTARY SURGICAL HANDICRAFT

By J. RENFREW WHITE, Ch.M., F.R.C.S. 243 Illustrations. 8s. 6d.

### PRACTICAL POINTS IN ANÆSTHESIA

By H. K. ASHWORTH, M.B., D.A. (R.C.P. & S.). 16 Illustrations. 7s. 6d.

J. & A. CHURCHILL LTD., 104 Gloucester-place, London W.1

## NOW AVAILABLE.

### PROGNOSIS.

VOLUME ONE.

Price 10s. 6d. net (postage 6d. extra).

Companion Volumes to the "Modern Technique in Treatment" and "Clinical Interpretation of Aids to Diagnosis" Series.

The first 66 articles of this series have been collected in book form. The Volume comprises 384 Demy Octavo pages, and is fully indexed under titles, authors, and broadly classified into groups to facilitate quick reference.

The Lancet Limited, 7, Adam-street, Adelphi, London, W.C.2.

### FRACTURES.

By MEURICE SINCLAIR, C.M.G., M.B., Ch.B. (EDIN.). With an Introduction by Sir ROBERT JONES, Bt., F.R.C.S. Pp. 550. 337 X ray photographs, photographs and diagrams. 24s. net.

Constable & Co. Ltd., London.

### BY LIEUT.-COL. ROBERT HENRY ELLIOT, M.D., B.S. Lond., F.R.C.S. Eng., I.M.S. retd.

A TREATISE ON GLAUCOMA.  
2nd Edition. Revised and Enlarged. 30s. net.

### TROPICAL OPHTHALMOLOGY.

With 7 Plates and 117 Illustrations. 31s. 6d. net.  
Spanish and French Editions, 1922. Full German Abstract.

THE CARE OF EYE CASES: 12s. 6d. net.

MANUAL FOR NURSES, PRACTITIONERS, AND STUDENTS.  
Chinese Edition. Oxford University Press.

THE INDIAN OPERATION OF COUCHING FOR CATARACT.  
7s. 6d. net. H. K. Lewis and Co. Ltd.

By H. CRIGHTON-MILLER, M.A., M.D., M.R.C.P.,  
Hon. Senior Physician, Inst. of Med. Psychology.

### INSOMNIA. An outline for the Practitioner.

Edward Arnold & Co., 41-43, Maddox-st., W.1. Price 10s. 6d.  
PSYCHO-ANALYSIS AND ITS DERIVATIVES.  
Thornton Butterworth, Ltd., 15, Bedford-st., W.C.2. Price 2s. 6d.

### IDEAL BIRTH.

HOW TO GET THE FINEST CHILDREN.

By TH. F. VAN DE VELDE, M.D.

(Author of "Ideal Marriage.")

Demy 8vo.

10s. 6d. net.

"This book is full of knowledge and wisdom and understanding. It is written by a gynecologist of experience. . . . He is writing for a public of fathers and mothers to be, nurses and midwives, doctors and the intelligent layman. . . . It cannot fail to impress itself upon many readers."—MEDICAL PRESS AND CIRCULAR.

Wm. Heinemann (Medical Books) Ltd., 99, Great Russell-street, London, W.C.1.

### DISEASES OF THE THYROID GLAND

WITH SPECIAL REFERENCE TO THYROTOXICOSIS.

By CECIL A. JOLL, M.S., B.Sc., F.R.C.S. (Eng.).

Crown 4to. Fully Illustrated. £3 3s. net.

Revista de Libros: "This book is the best clinical treatise which we possess to-day on the pathology of the thyroid. . . . The excellence of the text is greatly enhanced by the illustrations."

William Heinemann (Medical Books) Ltd., 99, Great Russell-street, London, W.C.1.

NOW READY. 2nd Ed. in 1 Vol., 854 pp. 811 Illus.

### EMERGENCY SURGERY. 50s. net; postage 8d.

By HAMILTON BAILEY, F.R.C.S.

BRISTOL: JOHN WRIGHT & SONS LTD. LONDON: SIMPKIN.

With 80 Illustrations. Demy 8vo. 9s. net; postage 6d.

### INJURIES AND THEIR TREATMENT

By W. ELDON TUCKER, M.A., B.Ch., F.R.C.S., Surgeon at St. John's Hospital, Lewisham; Surgeon to the London Clinic for Injuries, &c.

With a Foreword by Sir HUMPHRY ROLLESTON.

"This is the book for which medical men, especially general practitioners, have long been waiting."—MED. PRESS AND CIRC.

London: H. K. Lewis & Co. Ltd., 136 Gower Street, W.C.1.

### MOTIVES AND MECHANISMS OF THE MIND

By E. GRAHAM HOWE, M.B., B.S.

Hon. Phys., Tavistock-square Clinic for Functional Nervous Disorders.

Pp. 230. Demy 8vo. 7s. 6d. net.

FIRST VOLUME OF THE POST-GRADUATE SERIES.

### THE CONDUCT OF MEDICAL PRACTICE

BY

THE EDITOR OF "THE LANCET"

AND EXPERT COLLABORATORS.

Price 10s. 6d. net. Postage 6d. extra.

"The book is certainly comprehensive, and indeed may be described as complete."—BRITISH MEDICAL JOURNAL.  
London: THE LANCET LTD., 7, Adam-street, Adelphi, W.C.2.

## JOHN BALE, SONS & DANIELSSON, LTD.

### THE TREATMENT OF VENEREAL DISEASE IN GENERAL PRACTICE.

By THOMAS ANWYL-DAVIES, M.D., B.S. (Lond.), M.R.C.P. (Lond.) Post free 7s. 9d.  
"The best book on the subject that I have ever encountered."—KENNETH WALKER, O.B.E., F.R.C.S., in "Health and Empire."

### THE CURE OF HÆMORRHOIDS AND VARICOSE VEINS.

A Practical Guide to Modern Methods of Injection and Bandaging. By STEWART MCAUSLAND, B.A. (Lond.), M.D., Ch.B. (Lis.), M.R.C.S. (Eng.), L.R.C.P. (Lond.). Second Ed. With Illus. Post free 4s. 4d.  
"This book is well written, there are some good illustrations, and the teaching is practical."—BRITISH MEDICAL JOURNAL.

### ARTIFICIAL CRANIAL DEFORMATION: A Contribution to the Study of Ethnic Mutilations.

By Dr. E. J. DINGWALL, 55 Full Page Plates. 90 Illus. 5 Maps. £3 10s. net. Post free £3 12s.  
"Dr. Dingwall has brought together in this well-illustrated volume the materials for the consideration of one of the strangest customs ever invented by man."—LANCET.

### OTOSCLEROSIS: With special reference to Ætiology and Treatment.

By MACLEOD YEARSLEY, F.R.C.S. Post free 8s. 6d.

"A readable and succinct review of the history of the recognition and investigation of its characteristics."—MEDICAL OFFICER.

### THIS PANEL BUSINESS.

By A. G. P. Post free 11s.  
"Involving the Future of the General Practitioner of Medicine."  
"The book is well worth study. In it is summed up the result of much all-round observation."—BRITISH MEDICAL JOURNAL.

### New Pocket Monographs Each post free 2s. 8d.

### THE MINOR MEDICINE OF GENERAL PRACTICE.

By L. V. SNOWMAN, M.A., M.B. (Camb.), M.R.C.P. (Lond.).  
"It would be almost impossible to recommend a more useful book."—CLINICAL EXCERPTS.

### AN EPITOME OF THE LABORATORY DIAGNOSIS AND TREATMENT OF TROPICAL DISEASES.

By HORACE M. SHELLY, F.R.F.P.S., M.R.C.S., L.R.C.P., D.T.M. & H. (Eng.).

83-91, GREAT TITCHFIELD ST., LONDON, W.1

# ESSOGEN AND ADVITA

(VITAMIN A) (VITAMINS A and D)

*produced from natural sources only*

ESSOGEN is a highly potent concentrate of Vitamin A, free from Vitamin D. The advantages in this respect will be readily appreciated, as Essogen may be employed over a wide range of conditions where it is desired to build up the resistance of the patient. Many diseases are definitely associated with low liver reserves of Vitamin A, and it is known that modern diets are commonly deficient in their Vitamin A content. One of the functions of Vitamin A is to correct a state of "passable" health and make it "buoyant." Xerophthalmia, Night Blindness and Coeliac Disease are attributed to a deficiency of Vitamin A.

ADVITA is an accurately balanced concentrate of Vitamins A and D, and is derived entirely from natural sources.

Advita is indicated in all conditions where the object is to ensure the efficient assimilation of calcium. It will be found particularly suitable for administration to nursing or expectant mothers as well as in the treatment of a number of children's ailments.

More than twenty years have been spent in extensive research on the fat-soluble Vitamins A and D at the Lever Biological Laboratories in Port Sunlight. With the vast resources at their disposal and the most advanced methods of assay, the Lever Biological Laboratories are in a unique position in this field, and Essogen and Advita may be accepted with confidence as biologically assayed products of guaranteed potency and rigid standardisation.

New and Improved Packs,  
 ESSOGEN and ADVITA, now available.  
 Bottles of 30 Capsules 2/6 per bottle

# ADDRESSES AND ORIGINAL ARTICLES

## THE DIFFERENTIAL DIAGNOSIS OF DISEASES OF THE COLON

(DYSENTERY AND COLITIS) \*

BY PHILIP MANSON-BAHR, D.S.O., M.D. Camb.,  
F.R.C.P. Lond.

PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES,  
LONDON

(WITH COLOURED PLATE)

The subject of dysentery has extended enormously within recent years, and we at the present time possess a more comprehensive knowledge of the aetiology, diagnosis, and treatment of this condition than ever before.

The term "dysentery" itself denotes a symptom-complex; that is, the appearance in the stool, or in the form of an exudate derived from the bowel wall, of blood and mucus, either together or passed separately. It denotes therefore not one disease, but a whole congeries of conditions, fundamentally different from one another, to which this one sign is common.

The classification shown below is founded, as far as possible, upon an aetiological basis. It groups together all the different conditions, whether peculiar to the tropics or not, in which diarrhoea and dysenteriform symptoms are found. The list is a formidable one, but even now may not be complete.

### CLASSIFICATION OF THE DYSENTERIES AND ALLIED DISORDERS

#### THE DYSENTERIES

- |                         |                            |
|-------------------------|----------------------------|
| 1. Bacillary dysentery. | 3. Helminthic dysentery.   |
| 2. Protozoal dysentery. | (a) Bilharziasis.          |
| (a) Amebiasis.          | (b) Esophagostomiasis      |
| (b) Balantidiasis.      | and other worm infections. |

#### THE PSEUDODYSENTERIES

- |                          |                           |
|--------------------------|---------------------------|
| 1. Coccidiosis.          | 4. Malarial dysentery.    |
| 2. Giardiasis.           | 5. Leishmanial dysentery. |
| 3. Flagellate diarrhoea. |                           |

#### PATHOLOGICAL AFFECTIONS OF THE COLON RESEMBLING DYSENTERY

##### (a) Colitis Group

1. Mucous colitis and spastic colon.
2. Idiopathic ulcerative colitis.
3. Membranous colitis.
4. Colitis produced by foreign bodies.
5. Toxic colitis: (a) mercurial poisoning; (b) food poisoning (paratyphoid B); (c) uræmic colitis.

##### (b) MISCELLANEOUS GROUP

1. Tuberculosis of colon.
2. Syphilitic disease of the bowel.
3. Lymphogranuloma inguinale and rectal stricture.
4. Malignant disease and polyposis.
5. Diverticulitis.
6. Simple polypus.
7. Intussusception.
8. Internal hæmorrhoids.

The average person regards dysentery as being necessarily a somewhat disagreeable, or even dangerous, accompaniment of life in the tropics; but the genuine seeker after knowledge is bound to confess that the term "tropical" as applied to

dysentery is more convenient than real. Many of these diseases are found all over the world, and the conviction has gradually been forced upon us that their prevalence in the tropics is rather due to the lack of sanitary facilities than to any other dominating circumstance. In tropical lands, moreover, may be found many different forms of bowel diseases, and it is dangerous to presume that a patient from the tropics who is passing blood and mucus in the stools is necessarily suffering from one or other of the better known dysenteries, of which the aetiology is now well understood.

The diagnosis of dysentery, therefore, becomes a peculiarly definite clinical study, and it will be admitted that it is one of first-rate importance—mainly because the methods of treatment, as at present understood, differ so fundamentally that incalculable damage may be done by their inappropriate use.

### Bacillary Dysentery

Bacillary dysentery is an acute epidemic disease whose ravages are nowadays mostly confined to tropical countries, where the insanitary conditions are the chief factors in its dissemination. To the student of tropical medicine it presents itself as a disease of major importance and as one of the chief causes of disability and invalidism in tropical countries. From the point of view of the settler or the government official with a growing family, a special danger lies in its liability to attack small children, and to produce in them a very serious and sometimes fatal illness. It must not be thought, however, that bacillary dysentery does not occur in more temperate climates; for cases are still met with which originate in schools and other institutions in this country. It is well known as a constant and inveterate disorder amongst patients in lunatic asylums and at least five epidemics have been recorded in Great Britain during the last 15 years.

From the point of view of the clinician, it is unfortunate that not one bacillus but several varieties of organism have been found to produce the symptom-complex of bacillary dysentery. There appears to be no special geographical distribution peculiar to the three chief forms of bacillus. The main factors which emerge are that it is comparatively easy to isolate the specific organism from the dysentery stool early in the course of the disease and when the specimen is tested within a short period of being passed by the patient. This time-factor becomes more and more important in a tropical climate, where all putrefactive processes are greatly accelerated.

Bacillary dysentery is an acute disease as a rule, but it has, as have all other acute infections, a most varied symptomatology; all grades are found, from an acute and rapidly fatal choleric form attack, to a comparatively mild and afebrile disease. In the differential diagnosis, with which this study is mostly concerned, it is important to note that its chief symptoms are due to toxic absorption of dysentery toxins from the large intestine. Bacillary dysentery, in popular language, is "lying-down" dysentery, and it is necessary to see it and to realise the pathological state of the mucous membrane of the large intestine before one can appreciate the finer points in differential diagnosis.

The dysentery bacilli attack the mucous membrane itself, which undergoes all changes from simple catarrh to complete coagulation necrosis, and this process extends throughout the whole 4½ ft. of the

\*The Lettsomian lectures for 1936 delivered before the Medical Society of London on Feb. 17th and 26th and March 2nd.  
5875

large intestine, and also, in the majority of cases, spreads upwards into the lower part of the small intestine as well; so it is obvious that there is a large vascular absorbing surface to be considered in estimating the damage to the human organism produced by this infection. All stages, from hyperæmia to complete destruction of the mucous membrane, can be studied in serial sections, and the natural process of cure entails the casting off, or exfoliation, of this dead and toxic membrane and a regeneration of the cells which have been destroyed in the process.

Shiga's bacillus is responsible for the most acute and the most readily fatal forms, and this was the bacillus that loomed large in the days of the Great War. Of Flexner's bacillus it is not so easy to speak as a single whole, mainly because the bacteriologists have succeeded in subdividing it into numerous varieties. Only recently it has been recognised that there are five serological groups, or races, of this organism, which have been labelled V, W, X, Y, and Z, and no longer need we worry our heads about this and that bacillus which has been christened after one bacteriologist or another.

The latest addition to the dysentery group which has received general recognition is Sonne's bacillus, and it is probable that many of the minor forms of acute dysentery and diarrhœa which are common amongst travellers on their first introduction to the glories of tropical life are due to an infection with this organism. Sonne differs from the true dysentery bacillus in its ability to produce acid out of lactose, and, moreover, in the human body it behaves very much like members of the food-poisoning group. For it may produce either symptoms of dysentery with blood and mucus in the stools, or, on the other hand, the symptoms of a generalised blood poisoning.

#### ISOLATION OF CAUSAL ORGANISM

The diagnosis of bacillary dysentery by the actual isolation of the organism from the faeces is a complex process, and for complete bacteriological accuracy a period of 5-7 days is necessary. In this lies the explanation why the diagnosis of bacillary dysentery is so seldom made, and it also explains to a great extent the discrepancies which one finds in studying the vital statistics of various countries where the two main forms of dysentery, the bacillary and amœbic, exist side by side.

If the whole of the mucous membrane is severely damaged the death of the patient is bound to ensue. In lesser degrees of infection the necrotic process has a patchy distribution, and only small areas of the bowel are involved. At autopsy the dysentery bacilli can be recovered from the inflamed mucous membrane in the early stages of the disease; but once necrosis has taken place, it is only possible to isolate them by scraping away the dead and putrefying mucous membrane and culturing the exudate which lies beneath.

There is a chronic form of bacillary dysentery (Fig. 1) also to be considered. In this form, which is very important from the point of view of differential diagnosis, the more acute dysenteric symptoms are not observed, and the main symptom-complex is one of chronic diarrhœa, accompanied by anæmia and grave emaciation. Here the underlying pathology consists in grave disturbance of the mucous membrane of the large intestine by sinuous ulceration with formation of submucosal sinuses and fistulæ. Sometimes also inclusion cysts are formed in the submucosa, and in their contents the dysentery bacillus finds a convenient and safe refuge.

In these chronic dysentery bowels the dysentery bacillus, far from vanishing from the mucous membrane in a few weeks, can persist for months or even years; and though it may be comparatively easy to isolate the organism post mortem, it is very difficult to obtain it by culture from the faeces during life. It is this fact that has led me to doubt the value of routine examination for dysentery organisms; simply because failure to obtain them from the stools does not indicate that they were not present at the same time in the ulcers of the bowel.

#### EXAMINATION OF STOOLS

A certain amount of assistance in diagnosis may be obtained from the macroscopic appearance of the stools, though this rough-and-ready method of diagnosis cannot supplant the finer methods of bacteriological examination. In the acute stage of bacillary dysentery the stools passed per rectum do not consist of faecal matter. There occurs a spastic contraction of the descending and sigmoid colon, which can be palpated through the abdominal wall by the examining hand, and there is actually a damming-back of the faecal contents; so what is passed per rectum is the inflammatory exudate, the casting off of the dead and defunct mucous membrane attacked by the dysentery bacilli. This exudate is passed out in an almost continuous stream, and it is safe to term it a "dysenteric exudate." Its evacuation is accompanied by pain and spasm, or tenesmus, and the very frequent passage of the stools leads to exhaustion.

The physical characters are best expressed by saying that the exudate consists of blood-stained mucus which is viscid and jelly-like; it may be compared to red currant jelly. The microscopical examination of this exudate has been termed cytodagnosis, and though it is at best only a rough guide it is valuable in times of stress and strain. In the bacillary dysentery exudate the predominant type of cell is the polymorphonuclear leucocyte, which constitutes something like 90 per cent. of the cells. Moreover, it has been pointed out that these cells have undergone toxic necrosis with large ring-shaped and easily visible nuclei. With these cells are found a variable number of large hyaline refractile elongated or oval cells, which are known as "macrophage cells." Very often they contain in their interior ingested red blood corpuscles, or even leucocytes, in various stages of disintegration (Fig. 2).

It is possible to demonstrate, in microscopic sections of the submucosa, that these cells are originally derived from the endothelium of the capillaries. They are obviously, then, endothelial macrophages which have undergone "hæmatophagy." These constitute about 4 per cent. of the cells found in the stools in the acute stage of bacillary dysentery, and their significance lies in the fact that they represent the reaction of the organism to an acute infection; and furthermore they are of crucial importance in differential diagnosis because the uninitiated in cytodagnosis are liable to mistake them for stages of the dysentery amœba, *Entamoeba histolytica*.

There has been a feeling throughout the years of war, and the critical years that have succeeded it, that many mistakes are being made in the differential diagnosis of the dysenteries, from the liability to mistake these body cells for the dysentery amœbæ, and many so-called "epidemics" of amœbic dysentery can be explained upon these simple grounds alone. It is not difficult to contemplate all the serious results that may accrue from a simple mis-

interpretation of this kind, which may lead to the continuous treatment and possible intoxication of the patient by emetine therapy.

In addition to these, other cells may be demonstrated, such as columnar epithelial cells, derived from the bowel surface and scattered red blood corpuscles. From continuous and daily microscopic observation of dysenteric stools I have been able to show that the cytological picture varies considerably from day to day, and that when the disease has lasted a week or more, the typical cell picture is entirely obscured.

The clearer out the cytological picture, the easier it is to isolate the dysentery bacillus on culture. Under the most ideal conditions, as in the field laboratories in which I worked during 1916-18, no difficulty was experienced in the isolation of one or other of the well-known species of the dysentery bacilli in the earlier stages of the disease; but the longer the disease has lasted, the more difficult this isolation becomes, and the more prevalent become the atypical or aberrant forms of dysentery-like organisms, such as Morgan's bacillus. This naturally has an important bearing upon the treatment of the patient; the sooner the disease is recognised, the sooner appropriate treatment is initiated, the more rapid is the recovery. A diagnosis of bacillary dysentery demands the institution of saline treatment, the injection of antidyenteric serum, usually intravenously, into those who are most seriously afflicted with the disease, and the adoption of suitable dietary.

#### AGGLUTINATION TESTS

There are other scientific methods of effecting a diagnosis in bacillary dysentery. There is, for instance, the serological agglutination test. Unfortunately, from the point of view of the practical physician, this test is not of great value, for in the most acute and fulminating forms of the disease, where rapid diagnosis is essential, it very often fails. This is especially true in the acute Shiga infections, in which the agglutinins to Shiga's bacillus do not appear in the serum until the patient is convalescent from the disease, when it is obviously too late to be of practical importance. The chief value of the agglutination test lies in the differentiation of the chronic stages of the disease from other

FIG. 2.—Bacillary dysentery (Flexner infection). Exudate with numerous macrophage cells. Stained with phosphotungstic haematoxylin to show their nuclear structure.

forms of colitis, and especially from the chronic "ulcerative" type.

The less acute clinical forms are usually due to Flexner's bacillus, and here the special difficulty arises in interpreting agglutination response to this bacillus. Apparently it is necessary to employ for the agglutination test a mixed emulsion of all five races of the organism, and very little importance should be attached to any result unless there is a titre of over 1 in 100.

#### SIGMOIDOSCOPY

Finally, there are the sigmoidoscopic appearances of the bowel. It is usually unnecessary, or even inadvisable, to employ sigmoidoscopy in the acute stages of bacillary dysentery; but where it has been performed, as by Biggam in Cairo, the appearances of the mucous membrane of the rectum tally very closely with those observed in pathological specimens (Fig. A on Plate).

Sigmoidoscopy is especially valuable in differentiating chronic bacillary dysentery from the chronic amebic disease; in fact, sometimes it is the only method by which a differential diagnosis can be brought about. In chronic bacillary dysentery the mucous membrane of the large intestine, ranging even to the lower rectum, is covered with patches of bleeding and easily vulnerable granulation tissue. To the practised eye, this scattered appearance is characteristic, though it is difficult, on appearances alone, to differentiate it from ulcerative colitis.

FIG. 1.—Bacillary dysentery. Shows the formation of a chronic bacillary ulcer affecting only the mucous membrane and not penetrating beneath the muscularis mucosae. (Flexner's infection.)

FIG. 3.—Amebic dysentery. Section through the base of an amebic ulcer in the large intestine, showing large numbers of tissue-invading forms of *Entamoeba histolytica* and the characteristic tissue changes in the submucosa. Note the healthy appearance of the adjacent mucous membrane.

The main point is that in bacillary dysentery there is some degree of stenosis of the bowel, accompanied by rigidity of the intestinal tube which renders the introduction of the sigmoidoscope somewhat difficult to the operator and painful to the patient (Fig. B on Plate).

This subject will be discussed further under the sigmoidoscopic diagnosis of amebic dysentery.

### Amœbiasis

Amœbic dysentery, or more correctly, primary intestinal amœbiasis, is due to the invasion of the large intestine by the *Entamoeba histolytica*. In order to understand the true natural history of this disease, it is essential to envisage the dysentery amœba as originally a parasite of the submucosa.

As Dobell has pointed out, it is not in the interests of the parasite to destroy its human host, but rather to live in a state of symbiosis, or more properly, to coexist on friendly terms. There is, therefore, a continuous struggle between the ravages of the parasite and the efforts of the tissues to repair the damage effected by the entamœba, and there is also an absence, more or less, of the toxic factor which plays such a considerable part in bacillary dysentery. As will be seen, the damage to the bowel is purely local and mechanical, and results only in the destruction of a very small portion of the absorbing surface of the large intestine.

Recent experiences have pointed to the fact that amœbic dysentery is a water-borne disease. The infection is transmitted from one human being to another by the cyst form of the organism. This cyst, which has a characteristic morphology, appears in the fœces of the patient, often in enormous numbers, during the chronic stage of the disease, when the stools are formed and are faecal in character. It is quite impossible to transmit the disease from one person to another by means of the active or

vegetative form of the amœba. This active form, which is familiar to all students of pathology, is found only in the fœces, more especially in the blood and mucus exudate, in the active or acute stage of the disease, when the patient is passing dysenteric fœces.

The cyst, on being ingested, passes undamaged through the gastric tract, and on reaching the alkaline constituents of the small intestine the cyst wall is digested and the young amœba emerges. The observations of many investigators have shown that the next stage of the invasion of the bowel consists in the penetration of the glands of Lieberkühn by young amœbæ, till the fundus of the glands is pierced and the submucosa itself is entered. The entry is effected by means of the mechanical movements of the amœbæ as well as by cytolytic ferments which they secrete.

A typical amœbic ulcer, as seen in pathological specimens, is formed as the result of the bursting towards the lumen of the bowel, of what is, in fact, an abscess of the submucosa. The resulting ulcer is what is known as a flask-shaped ulcer—that is, one with a narrow neck and a broad base (Fig. 3).

It is easy also to envisage other results which may accrue from the presence of such a submucosal lesion; for instance, the amœbæ may invade the submucosal blood-vessels, causing thrombosis and gaining entrance to the portal blood stream, and in this way the invasion of the liver by amœbæ, which is such a frequent complication of intestinal amœbiasis, may take place. Large blood-vessels too may be penetrated by an extension of the abscess, and this may lead to a fatal intestinal hæmorrhage. If, however, the extension of the abscess should be towards the peritoneum, then the perforation of the large bowel occurs with consequent fatal peritonitis.

From the brief consideration of these pathological details we can gather the probable course of events of an amœbic infection. It will be understood that the blood and mucus exudate containing the pathogenic amœbæ is squeezed out of the ulcers by the peristaltic action of the large intestine, and this in turn explains the chief characteristic of the amœbic

FIG. 4.—Amebic dysentery. Exudate of amebic dysentery showing trophozoites of *Entamoeba histolytica* containing ingested red blood corpuscles. (Stained with phosphotungstic hæmatoxylin.)

stool and assists in differentiating between it and the bacillary exudate.

The patient suffering from amœbic dysentery, however acute the clinical symptoms may appear, does not bear the stigmata of an intestinal toxæmia, mainly because the toxins are not produced by the parasite itself. The lesions of the bowel are a mechanical rupture of the mucosal surface, so that the greater part remains normal in appearance and function. The course of amœbic dysentery is, therefore, usually quite apyrexial; the stools are fewer in number and more fœcal in character than in the bacillary disease, and as a rule there is no pain or abdominal tenderness. Tenesmus is extremely rare. The fact is that amœbic dysentery is a chronic prolonged disease and may coexist with comparatively good health. I have investigated and treated cases which have been known to be infected with the dysentery amœba for 30 to 40 years.

#### THE STOOLS

The macroscopical characters of the amœbic stool correspond with what might be expected from a study of the pathology of the disease. They are generally loose and diarrhœic in character, large in amount, and usually very offensive, owing to the decomposing blood which they contain. The admixture of this dark tarry blood has led to their comparison to "anchovy sauce."

The microscopical appearances are also of value in differentiation. In contradistinction to bacillary dysentery, the polymorphonuclear cells are almost entirely absent, and wherever some intestinal debris is present, the cells have a ragged outline and are of a "mouse-eaten" appearance. The red blood corpuscles are massed together in clumps or rouleaux, and a large number of contaminating micro-organisms are visible.

Then there are Charcot-Leyden crystals. These are generally associated with active forms of *E. histolytica* and considerable diagnostic importance has been ascribed to their presence by various authorities, such as J. G. Thomson, A. Robertson, H. W. Acton, and others (Fig. 4). It is felt, however, that some protest should be made against the practice, which has become prevalent, of diagnosing amœbic dysentery upon the presence of these crystals alone. They are found in many other pathological conditions of the large intestine, and I have seen them in association with thrombosed piles, carcinoma of the rectum, ulcerative colitis, and coccidial infection of the large intestine. It is probably more correct to state that, if these crystals are present in the fœces in large numbers, a more prolonged search should be made for the dysentery amœba.

Finally, as regards the entamœba itself, it must be emphasised once more that in order to find these organisms in their active state in the fœces, the specimen must be examined microscopically within a short period of being passed, and furthermore, warming of the preparation encourages the amœboid movements and renders them more easily recognisable. Sometimes, even in a blood and mucus stool, a prolonged search is necessary in order to find amœbæ, and very often they occur in clumps or in congregated masses. Sometimes, even, cases are met with in which a search of the stools has failed to reveal amœbæ, but they have been obtained subsequently in large numbers in preparations made direct from the intestinal ulcers by a proctoscopic examination. From the consideration of these circumstances it is quite easy to understand that when specimens of

fœces are dispatched in containers to the laboratory by post, the correct diagnosis is often missed because the organisms are dead.

A further word of warning is necessary—namely, that when once the active *E. histolytica* is dead it disintegrates with great rapidity, and soon becomes entirely unrecognisable as such under the microscope.

In the chronic stage of the disease the difficulties of diagnosis are often considerable. Chronic amœbic

FIG. 5.—Balantidial dysentery. Section of the large bowel through an ulcer, showing the distribution of the balantidium in the submucosa.

dysentery parades itself under a great number of clinical forms, and may resemble almost any other form of chronic intestinal disease. One of the chief symptoms is diarrhœa alternating with constipation. It may, moreover, produce signs and symptoms of a chronic appendicitis or, on the other hand, it may provoke a train of events which more resemble those of diverticulitis than of any other recognisable intestinal condition.

Chronic amœbiasis is usually associated with some chronic enlargement of the liver and an earthy waxy appearance of the skin. Its absolute diagnosis rests upon the discovery of the characteristic cysts of *E. histolytica* in the fœces. These may be present in enormous numbers, or they may be extremely scanty. The recognition of these cysts with certainty can be attained only after considerable practical experience. They have to be differentiated from the somewhat similar cysts of other intestinal protozoa, which may be present in the stools, but the identification of a single cyst with certainty is as important as the recognition of many, for in this case "one swallow makes a summer."

There is another difficulty which is often encountered and which is not easy to explain, and that is the intermittent appearance of these cysts in the fœces. One day they may be extremely numerous, and on the next prolonged search may fail to reveal a single one.

#### DIRECT EXAMINATION OF THE BOWEL

In view of the difficulties related above, sigmoidoscopy is playing a very important rôle in the diagnosis of this condition (Figs. C, D, and E on Plate). In

the acute stage of the disease, the sigmoidoscopic appearances are quite characteristic and the amœbæ may be identified in preparations made through the sigmoidoscope from the lesions themselves. The main point that strikes the observer is the pale and somewhat anæmic appearance of the undamaged mucosa together with an extra-elasticity of the folds of the bowel itself. On the introduction of the instrument into the rectum this corrugated appearance of

FIG. 6.—Bilharzial dysentery (Egyptian case). Showing eggs of *B. hematobium* and *B. mansoni* deposited in the submucosa and ulcerating their way through the mucosa into the lumen of the bowel.

the mucosa becomes instantly visible. The amœbic lesions are characteristic and consist of small punched-out ulcers surrounded by red areolæ or small yellow elevations which may be compared to the craters of microscopic volcanoes. There are generally interspersed between them numerous but small submucosal hæmorrhages. In the chronic stage the lesions are so minute that they can be discovered only by the use of a magnifying eye-piece. They are represented by small indentations or puckering of the mucosa, which represent the sites of healed or healing ulcerations. It is estimated that characteristic lesions are visible in the rectum and lower sigmoid in quite 75 per cent. of all amœbic cases. There remains, however, a residuum of 25 per cent. in which the lesions are situated higher in the bowel and beyond the reach of vision of the modern sigmoidoscope.

#### DIAGNOSTIC USE OF EMETINE

Before leaving the subject of amœbic dysentery it is necessary that some reference should be made to the therapeutic diagnosis of the disease. Unfortunately there always remains a small number of cases in which, although symptoms of diarrhœa and abdominal discomfort persist, yet no evidence of active amœbic infection can be verified. In these cases of doubt the experimental therapeutic injection of emetine is permissible. Should the more urgent symptoms clear up as the result of this course, then the practitioner has every right to regard the case as being one of amœbic infection. There are many grave objections to recommending this course as a

routine practice, but there are instances in which it must be resorted to.

#### Balantidiasis

Balantidiasis is a disease closely resembling amœbic dysentery in its course, but it is produced by the largest intestinal ciliate protozoan known, the *Balantidium coli*. This is a common parasite of the pig and of many monkeys, in all of which it may cause a fatal form of dysentery. Balantidial dysentery is such a rare disease in man that it is more of a medical curiosity than anything else. The human cases which have been recorded in the United States of America, Germany, Russia, and Italy have been in people who are closely associated with pigs, such as swineherds and pork butchers, and only occasionally have fatal infections been recorded. The pathology of the disease is very similar to that of amœbic dysentery, and in sections of the colon the balantidia can be demonstrated in large numbers in the submucosa and at the bases of the characteristic ulcers (Fig. 5). They are much larger and more conspicuous than are amœbæ in a similar situation. The diagnosis of balantidiasis is easily effected by the discovery of this large and conspicuous parasite in the fæces. Unfortunately the treatment of this infection has so far proved to be very unsatisfactory.

#### Bilharzial Dysentery

Apparently all three species of the bilharzia parasite which inhabit man are capable of giving rise to lesions in the large intestine, which take the form of ulcers or adenopapillomata, in which the characteristic eggs of the particular parasite can be found. The three species are *B. mansoni*, *B. hematobia*, and *B. japonica*. The eggs of these parasites are found in the fæces and each has distinctive character, so that it is unnecessary to particularise further (Fig. 6).

The bilharzia diseases have definite and well-defined geographical distribution. *B. mansoni*, which is the chief producer of dysenteric symptoms, ranges throughout almost the whole of Africa, and is occasionally found in the West Indies and South America. Therefore it is only in persons who emanate from areas where the disease is indigenous that the suspicion of this diagnosis can be entertained. In tropical practice, of course, this is an important matter. The diagnosis is made absolute by the discovery of the eggs of the parasite in the fæces. Often they can be found in the blood and mucus with which the faecal mass is covered, and, as a general rule, it is more advantageous to examine the outer layers of a formed motion rather than the centre portions. Rarely there is profuse diarrhœa with this infection, as in the other forms of dysentery. Some assistance is obtainable by a study of the cellular exudate in the fæces which usually contains a large number of eosinophil cells. Sometimes, especially in the case of *B. mansoni*, the characteristic eggs may be very scanty and difficult to demonstrate in the fæces, and in these, methods of concentration, such as that of Fülleborn, are employed.

The sigmoidoscopic examination is of great value and the pedunculated growths can be seen in the upper part of the rectum where they are quite characteristic. Portions of them may be removed by suitable forceps, crushed and placed under the microscope, in order to demonstrate the eggs. Sometimes in heavily infected persons, as in native Egyptians, the characteristic growths can be felt by digital examination of the rectum.

The earliest appearance of bilharzial dysentery in the bowel consists of small granulating areas

(Fig. F on Plate), and sometimes small elevated papules which more resemble tuberculosis, but these are usually seen in early European infections.

### Oesophagostomiasis

As a matter of academic interest it is necessary to mention the rare nematode, *Oesophagostomum apistomum*. This is the worm which inhabits the cæcum and colon of monkeys in Africa, the Philippines, Brazil, and China, and has been found in native prisoners in the gaols of Northern Nigeria. The female worms, which measure 2 to 3 cm. in length by 1 mm. in breadth, are found encysted beneath the mucous membrane of the large intestine and give rise to dysenteriform symptoms. The diagnosis is made by the discovery in the fæces of the eggs of the parasite. The eggs measure 60  $\mu$  in length by 40  $\mu$  in breadth, and closely resemble those of ancylostoma, except that the contained embryo is in an advanced stage of development.

KING'S COLLEGE HOSPITAL, LONDON

### II.—SODIUM DEFICIENCIES IN CLINICAL MEDICINE (continued)

#### The Secretion of Urine

All the conditions now under discussion are liable to be accompanied by a rise in the blood-urea. O'Shaughnessy,<sup>241 242</sup> studying cholera in 1831-32, was, I think, the first to draw attention to this. Colin<sup>53</sup> noted it in 1868 in diabetic coma, so you see it is not a new discovery. It was not detected in intestinal obstruction till 1914,<sup>319</sup> but since that time it has frequently been observed clinically<sup>19 29 35 36 40 44 47 58 68 71 85 94 105 113 126 159 163 168 176 184 186 202 203 204 218 219 230 254 256 258 259 260 263 277 281 284 312 325</sup> and produced experimentally through dehydration or removal of the intestinal secretions.<sup>10 56 77 79 84 92 102 111 112 114 115 116 117 118 120 136 141 152 159 199 240 283 329 330 331 339</sup>

It is well recognised in Addison's disease.<sup>13 85 130 275 292 293 305 309 311 346</sup> It has been reported also by a number of clinical observers in an ill-defined but rather interesting group of cases, sometimes with signs of true nephritis, in which hypochloræmia, often of unproven origin, was a cardinal sign and the suggested cause of the high blood-urea.<sup>23 25 47 153 156 225 244 261 263 268 272 304</sup> It is possible that the high blood-ureas of uncompensated alkalosis<sup>18 237</sup> with hypochloræmia should be included here although there is no hyponatræmia. A considerable literature has grown up on the secretion of urine in diabetic coma which has been reviewed by McCance and Lawrence.<sup>188</sup> In this disease the blood-urea may be high when the patient comes under observation, or it may at this time be relatively normal and only begin to rise as insulin treatment proceeds. It may then go up in the course of 6 or 8 days to 250-300 mg. per 100 c.cm.

\* The Goulstonian lectures for 1936, delivered before the Royal College of Physicians of London on March 5th, 10th, and 12th. Lecture I. was published on March 21st; Part I of Lecture II. last week; and Lecture III. will appear in a forthcoming issue.

The post-mortem and other anatomical evidence gives no satisfactory explanation of why the blood-urea should rise in any of these diseases.<sup>44 58 176 188 199 216 223 225</sup> Morbid appearances have naturally been described,<sup>294</sup> but there is no unanimity about them and all are agreed that the kidneys are quite unlike those of chronic interstitial nephritis, sublimate poisoning, or any other condition in which a similar retention of urea may be encountered. Further, if the patient recovers from the intestinal obstruction or diabetic coma, renal sequelæ have never been recorded. One must therefore conclude that the abnormality is a temporary one of function only, and not a permanent one of structure. I wish now to discuss possible explanations of this rise of blood-urea which have been suggested from time to time. I say "suggested" purposely, for few of them have been tested experimentally. Let me begin by examining any other evidence we possess as to the function of the kidney in these conditions.

Our knowledge of the excretion of urinary constituents other than urea is unfortunately fragmentary and rather contradictory. Salt deficiency so upsets the water balance of the body that the excretion of water may become very abnormal. In both clinical<sup>208 274 275</sup> and experimental<sup>267 289 290</sup> Addison's disease, for example, the excretion of ingested water is very much delayed, but under the circumstances this is no real proof of renal deficiency. In chronic interstitial nephritis the kidney does not respond to ingested water with a diuresis, but here the kidney is partially destroyed and this is the primary cause of the abnormal water metabolism. For this reason I shall not include chronic interstitial nephritis in my discussion of the secretion of urine during salt deficiency. Apart from these two diseases, oliguria is the rule in clinical salt deficiency, but this is to be expected since clinically the causes of salt loss are also causes of water loss. Some authors have found that a rise in blood creatinine, or uric acid, accompanied the rise in the blood-urea,<sup>40 56 176 203 207 219 343</sup> and obviously if no urine is being passed this must occur. Others have found the reverse.<sup>113 115 338</sup> After diabetic coma the creatinine rises in the blood pari passu with the urea, but the excretion of ammonia remains normal.<sup>188</sup> The same is probably also true of the excretion of ammonia after severe diarrhoea<sup>218 282 286 287 315</sup> or loss of pancreatic juice.<sup>136</sup> Many have found intestinal obstruction to be accompanied by a subnormal excretion of phenol sulphone phthalein,<sup>71 113 109 223 263 281 319 345</sup> but others again have shown that the secretion of the dye may still be normal even when the blood-urea has been raised or when other signs of renal deficiency are present.<sup>259 290 319</sup> Louria's observation is of little value as saline had been given before the phenol sulphone phthalein. This dye, however, is a comparatively insensitive test for deficient function.<sup>76</sup> It is, moreover, probably excreted both by glomeruli and tubules,<sup>147 288</sup> so that it must be regarded as an unsatisfactory substance on which to base physiological argument. Schafer<sup>279</sup> has stated that in experimental Addison's disease the kidney does not lose its ability to concentrate nitrogenous substances in the urine. We may, therefore, conclude in general terms that signs of functional renal failure are common but that the excretion of urea, as judged by the height of the blood-urea, may appear to be defective while other functions of the kidney are still relatively normal.

Besides excreting nitrogen the normal kidney helps to regulate the pH of the plasma, and this is one of the functions which may undoubtedly fail in severe salt deficiency. Failure is most obvious

during a proved alkalosis when the urine may be found to be acid instead of alkaline.<sup>1 40 71 91 105 140 218 219 238 302</sup>

I wish now to discuss the reasons which have been suggested for these signs of renal failure.<sup>33 35 58 85 94 156 168</sup> Before I begin let me remind you that the volume of water excreted per day is probably controlled by humoral factors and by the pituitary gland. After mild loss of fluids by sweating, or after a reduced water intake, the volumes of urine may become very small indeed without any evidence of a reduction in the rate of glomerular filtration. Conversely the daily excretion of water may be normal or excessive when glomerular filtration and the power to excrete creatinine and urea is certainly reduced. The volume of the glomerular filtrates is always so *much* larger than the volume of urine that it is easy to see how this can be so. Extreme reduction of glomerular filtration must naturally reduce the volume of urine.

The first reason to be discussed is the fall of blood pressure. It is current knowledge that if the spinal cord is cut the secretion of urine stops because the blood pressure falls below the level at which glomerular filtration can take place. A fall of blood pressure is the rule in diabetic coma and Addison's disease,<sup>8 188 311</sup> and must reduce the glomerular pressure unless the efferent glomerular arterioles can maintain it.<sup>322 342</sup> I am satisfied that a fall in arterial blood pressure is not always the cause of the renal failure after diabetic coma,<sup>188</sup> and I do not think that a small fall should necessarily affect the volume of urine or the concentrating power of the tubules, provided the latter remain adequately nourished.<sup>321</sup>

Secondly, dehydration has often been invoked to explain the signs of renal failure.<sup>12 92 131 159 223 281 305 346</sup> This suggestion requires amplification in terms of what is known of renal physiology. The circulating blood,<sup>13 158</sup> which may be greatly reduced in volume, may only be able to fill a proportion of the normal number of capillaries in the body. If this applies to the renal circulation, the number of active glomeruli will be reduced, and hence the rate of glomerular filtration. The urine volumes will vary according to the cause of the anhydræmia. If this has been caused by severe water deprivation, the daily volumes of urine will be very small. These are the conditions met with after prolonged vomiting or excessive exposure to high external temperatures. If the anhydræmia has been caused by a loss of sodium salts, it may be accompanied by a normal fluid intake and by normal daily volumes of urine. This is the position in Addison's disease (see Lecture III.). The reduction in glomerular filtration, however, may be one of the factors which prevents the kidney developing its normal rate of diuresis after water ingestion. The excretion of solids should depend upon the rate of glomerular filtration rather than the urine volumes, although their excretion may not be quite so efficiently carried out when the volumes of urine are very small.<sup>78</sup>

Thirdly, a fall in plasma volume will cause a rise in the plasma proteins and hence in the colloidal osmotic pressure of the plasma. This will reduce the glomerular filtration unless the arterial blood pressure rises in compensation. We know that it does not. The efferent glomerular arterioles may of course constrict and so maintain glomerular pressure. Urine volumes should not be affected.

Fourthly, increased viscosity of the blood, which undoubtedly occurs<sup>13 119 128 145 196 211 269 270</sup> owing to the increased number of red cells per c.mm., may

decrease the circulation-rate and so reduce the efficiency of the kidney.

Fifthly, an uncompensated alkalosis, which often accompanies loss of the intestinal secretions, may in itself greatly diminish the capacity of the kidney to excrete urea and creatinine<sup>18 55 237</sup> (see Lecture III.). This probably means decreased glomerular filtration. If there is no sodium deficiency an uncompensated alkalosis results in polyuria in spite of the diminished glomerular filtration, but if there is a sodium deficiency the result is an oliguria (Lecture III.). The reason for this difference is not at present clear.

Sixthly, the kidney cells may be specifically injured by salt withdrawal so that the organ cannot function efficiently.<sup>33 85</sup> This suggestion is difficult to refute but requires experimental support to make it an attractive explanation. Other suggestions have been made<sup>42</sup> which I do not intend to discuss.

Lastly, there are factors affecting the secretion of urine which we all recognise although we cannot explain. I refer to the causes of those mysterious post-operative anurias, reflex anurias, and the anurias of acute nephritis, and so on.<sup>65 143</sup> Equally mysterious anurias are met with experimentally.<sup>3 5 6 61 63</sup> Some anurias—e.g., in acute nephritis—may be due to the tubules becoming so functionless that the whole of the fluid filtered off in the glomeruli is reabsorbed again, as it is in the peripheral lymph system.<sup>296</sup> We may have to relegate the anuria following diabetic coma to this unsatisfactory group.

These explanations account satisfactorily for the generalised fall in renal efficiency of which we have had evidence. The excretion of water demands special consideration, and it is important to distinguish a reduction in glomerular filtration from a reduction in total urinary volume. Patients may have rising blood-ureas and other signs of diminished glomerular filtration in the presence of a copious flow of urine.<sup>55 188 204 237</sup>

None of the reasons so far advanced explains why the excretion of *urea* should appear to be predominantly affected. One explanation for this is the excessive tissue breakdown. We have evidence from the nitrogen balances that this is going on, and many authors have had to postulate it to explain the rising blood-ureas which have been observed in spite of high rates of excretion.<sup>102 120 197 222 225 240 259 325 337</sup> It would obviously be possible in this way to get very high blood-ureas with perhaps no rise in blood creatinines and no change at all in phenol-sulphone-phthalein excretion. Urea-clearance tests would be invaluable under these circumstances and should always be done.

Blum considered that the rise in blood-urea was due to the "manque de sel."<sup>25 26 27</sup> The urea was reabsorbed to raise the subnormal osmotic pressure of the plasma. This you will remember is the normal state of affairs in the dogfish. The theory was evolved to explain the renal disorganisation following diabetic coma. It does not do so satisfactorily, for I have seen patients with reasonably high blood pressures filled with saline after coma till they were œdematous—and still no urine came. The theory does not explain the simultaneous retention of creatinine. Urea, moreover, even if reabsorbed, would not regulate the osmotic pressure of the plasma as originally conceived, for the substance permeates freely through all the tissues of the body. In the dogfish this was what was wanted because the osmotic pressure of the whole body was being raised relative to the liquid environment. In the mammal nothing can act as an efficient substitute for an extracellular electrolyte unless its distribution is limited to the

extracellular fluids. Glucose,<sup>339</sup> for example, or potassium chloride<sup>118</sup> would be quite useless. Nevertheless a consideration of the normal urea clearances and the glomerular filtration rates at high or low levels of water excretion suggests that some reabsorption of urea may always take place. Blum's theory then merely postulates the exaggeration of a normal process. Moreover, some of the experimental evidence is in keeping with reabsorption,<sup>21 80 81</sup> and until the results have been explained in some other way we cannot altogether dismiss reabsorption of urea as a cause of some of the high blood-ureas met with during salt deficiency. It is true that in acute water poisoning there may be no rise of blood-urea,<sup>297</sup> and considerable hypochloræmia and fall of serum osmotic pressure may occur in very young dogs without any rise of "Reststickstoff,"<sup>159 160</sup> but evidence based on the reactions of very young animals should be treated with caution. After all, new-born mice can survive an hour in pure nitrogen,<sup>154</sup> but no one would suggest that adult men could do the same.

### Medical Importance of Salt Deficiency

Minor degrees of deficiency must be quite common in the tropics,<sup>172 193 194</sup> and should be suspected if the urine does not contain normal amounts of chlorides. The danger of salt deficiency to miners, stokers, and others who have to work in very hot atmospheres is now unquestioned.<sup>78 229 314 340</sup> While no one would attribute the gravity of diabetic coma or intestinal obstruction to salt deficiency alone, it is certain that a loss of salt may be a very serious matter and may by itself have fatal consequences. The experimental work leaves no doubt of this. Rabbits can be killed in a few days by diuretin which produces a forced excretion of chlorides in the urine.<sup>21 109 110 222</sup> Removal of pancreatic,<sup>77 330</sup> gastric,<sup>102 136 329</sup> or intestinal juice,<sup>146</sup> without interrupting the continuity of the gut, is fatal, although it seems that animals suitably nourished can survive a loss of pancreatic juice for a considerable time.<sup>34</sup> Whatever the actual cause of death in intestinal obstruction, no one nowadays will dispute the gravity of the loss of the extracellular salts or the value of replacing them by giving saline. This is even more obvious in the acute gastro-enteritis of children. It is not quite right to attribute the bad effects only to the removal of sodium salts, for loss of gastro-intestinal secretions means loss of water as well. If water can be taken by mouth and absorbed, then a condition more akin to simple salt loss is obtained, but, in giving saline, water and salt are restored together and in most instances the beneficial effects are due to both.

Loss of salt is such an important feature of suprarenal removal or destruction that it may almost be said to constitute the disease. Clinically it is true that salt cannot yet be regarded as a complete cure, and some of the experimental findings—e.g., the interference with fat absorption—are perhaps difficult as yet to reconcile with a simple loss of sodium salts. Harrop et al.,<sup>128</sup> however, have been able to keep bilaterally suprarenalectomised dogs alive and in good condition for months with sodium chloride and bicarbonate alone. Signs of deficiency at once developed when this treatment was discontinued.

### Treatment

I have already touched upon this, and there is no need to emphasise facts which are already generally known. There are, however, one or two points which I should like to discuss. The first is the question of whether one should incorporate sodium bicarbonate or lactate in the solution of sodium

chloride to be administered. The question arises in diabetic coma and severe diarrhœa, which produce acidosis, and also in Addison's disease. In diabetic coma the acidosis is due to substances which the administration of insulin will remove. It seems unnecessary therefore to give bicarbonate with the saline, and the tendency nowadays in this country is, I think, not to do so. After severe diarrhœa without vomiting, some bicarbonate is probably beneficial, but in the acute gastro-enteritis of children acidosis or alkalosis may be present according to whether diarrhœa or vomiting has predominated. Unless the presence of acidosis has been correctly diagnosed, it is safer to give a simple saline solution, and this should always be used in cases of alkalosis. May I remind you that the most severe alkalosis may be accompanied by an acid urine. Never be misled by the reaction of the urine into giving such a patient bicarbonate or any other form of alkali.<sup>132</sup> It would probably be fatal. Hartmann and others<sup>133 134 137 212</sup> have advocated the substitution of Ringer solution for simple saline and the addition of sodium lactate in cases of acidosis. This salt is converted slowly to bicarbonate in the body,<sup>138 139</sup> and is claimed to be safer and more efficient than the latter for parenteral administration.

Harrop et al.<sup>128</sup> combined sodium lactate or bicarbonate with the sodium chloride, which they administered to their suprarenalectomised dogs, and considered that it was an important part of their successful treatment. It may have been, and if so it is possible that the combined salts would be much more efficacious clinically than sodium chloride alone. Systematic trial will no doubt settle the matter, and meantime I think the evidence is good enough to suggest that bicarbonate should be combined with the chloride.

The second detail of treatment which I wish to discuss is whether normal or hypertonic saline should be used. This obviously depends upon the circumstances, and Hartmann has actually described six different brands of salt solutions and the indications for their use.<sup>134</sup> I feel that this is making things unnecessarily complicated. If one can have a complete chemical examination made of the blood, one can prescribe almost exactly the salts and water required to restore normality, but few English physicians would consider it advisable to wait for such analyses before beginning treatment; nor do I think it necessary, but my experience of children is very limited. The safest solution to use is normal saline or Ringer's solution. Hypertonic saline should only be employed when it is specially indicated as in cholera and diabetic coma—and in the latter only in reasonable quantities.

## MANDELIC ACID AND AMMONIUM MANDELATE

### IN THE TREATMENT OF URINARY INFECTIONS

BY H. E. HOLLING, M.B., M.Sc. Sheff.,  
M.R.C.P. Lond.

MEDICAL CLINICAL ASSISTANT, ROYAL INFIRMARY,  
SHEFFIELD; AND

ROBERT PLATT, M.D. Sheff., F.R.C.P. Lond.  
PHYSICIAN TO THE ROYAL INFIRMARY

The episodes leading up to the treatment of urinary infections (pyelonephritis) with mandelic acid can be briefly summarised as follows.

In 1931 Helmholtz and Clark<sup>1</sup> introduced the ketogenic diet as a means of treating these conditions, the rationale being the observed fact that the urines of diabetic patients with ketosis and of epileptic patients undergoing ketogenic treatment were less subject to bacterial decomposition than those of other patients. The treatment was remarkably successful, and Fuller<sup>2</sup> in 1933 showed that its effect was due to the presence of  $\beta$ -hydroxybutyric acid in the urine. The difficult and unpalatable ketogenic diet could not be replaced by oral administration of  $\beta$ -hydroxybutyric acid, however, because that acid is completely oxidised in the body. Rosenheim<sup>3</sup> in 1935 found the necessary substitute in mandelic acid ( $C_6H_5.CHOH.CO_2H$ ) which is excreted unchanged in the urine and exerts a bacteriostatic effect if the urine is kept sufficiently acid. Clinical trial seemed to give promise of success, and this has since been confirmed by a series of 16 cases of urinary infection reported by Lyon and Dunlop,<sup>4</sup> in all but 3 of which the urine was rendered sterile. The present paper is a report on 29 cases.

#### METHOD OF TREATMENT

Of the 21 hospital cases treated, 13 were in-patients and the remainder out-patients. There were also 8 private patients, 3 of whom were in bed during the treatment.

Catheter specimens of urine were first examined to determine the nature of the infection, and pyelography (retrograde or intravenous) was performed where necessary, to exclude pyonephrosis, calculus, tuberculosis, &c.

The first few hospital patients were given mandelic acid, neutralised by sodium bicarbonate as described by Rosenheim. Later the sodium salt was prescribed as follows:—

Sodium mandelate.. ..	..	..	50 grains.
Syrup of orange .. ..	..	..	1 drachm.
Water to 1 ounce.			

In water four times daily.

This was preceded by:—

Ammonium chloride .. ..	..	..	30 grains.
Liquid extract of liquorice ..	..	..	15 minims.
Water to 1 ounce.			

Four times daily.

Fluid intake was restricted during treatment to two pints daily, unless thirst was complained of, when more fluid was allowed.

The acidity of the urine, which must attain a pH of 5.3 or less, was tested by the addition of five drops of methyl-red solution to 2 c.cm. of urine. This gives a bright pink colour if the urinary acidity is satisfactory, but an orange or yellow colour if it is too alkaline. The amount of ammonium chloride

administered was then increased or reduced accordingly. As a rule, a satisfactory acidity can be produced with about half the dose prescribed above. In private patients the ammonium chloride was given in 1.0 gramme capsules (4–8 daily).

Finally, 4 cases were treated by ammonium mandelate (see later).

Specimens of urine were examined at two-day intervals where possible. When the deposit (examined as a wet film) showed only a few leucocytes and no bacilli, cultures were again made from catheter specimens.

#### COMMENT

The results of treatment are set out in the accompanying Table, and it will be seen that in every uncomplicated case of acute or chronic pyelonephritis (abbreviated to "pyelitis") the urine was rendered sterile by mandelic acid treatment in from 2 to 21 days. The failures (5 out of 29) may be considered in further detail.

CASE 4, a man of 53, had prostatic calculi, though no enlargement of the prostate could be made out. He felt better when taking mandelic acid.

CASE 9 had tuberculosis of the kidney and bladder, with a secondary infection with bacillus coli. Mandelic acid and ammonium chloride made the symptoms worse and she only took the treatment intermittently.

CASE 11 was a woman very ill with pernicious anæmia, degeneration of the cord, uterine prolapse, and a severe urinary infection. She died during treatment, apparently from general weakness.

CASE 12 was a young woman who had had the right kidney removed three years previously for a growth (adenomyoma) involving the ureter. She had had a severe pyelonephritis of the other kidney ever since, which ketogenic diet failed to clear up. Early in 1935 an attempt was made to catheterise the left ureter but was unsuccessful owing to the very severe cystitis. Her condition in November, 1935, was so miserable with frequency and dysuria that although renal insufficiency was suspected it was thought that mandelic acid might be tried as a last resort. She refused to come into hospital or to have any further investigation before treatment. The ammonium chloride caused extremely severe dyspnoea which was no doubt due to acidosis. A satisfactory urinary acidity could not be produced; treatment was stopped after three days.

CASE 16 had *B. coli* septicæmia. Post-mortem examination showed pyonephrosis and perinephritic abscess.

It will thus be seen that with the exception of Case 4, and possibly Case 11, none of the failures were really suitable for mandelic acid treatment.

During treatment a few casts and a trace of albumin occasionally occur in the urine. The treatment is obviously unsuitable in the presence of renal insufficiency because badly damaged kidneys cannot excrete a sufficiently acid urine or a sufficient concentration of mandelic acid. Nevertheless the presence of nephritis in an earlier stage does not appear to be a contra-indication, as is shown by the two cases (Nos. 3 and 27) in which renal œdema was present. The superimposed urinary infection was cleared up in each without any apparent change in the course of the nephritis. In Case 1 (hypertension without renal insufficiency) the course of the disease also was unaffected, except favourably by the removal of the symptoms of urinary infection.

Of the other cases, Nos. 13 and 17 relapsed. The former was again successfully treated. Case 18 had previously had scarlatinal nephritis; intravenous pyelography showed slight stenosis of the right ureter and a ureteric catheter was therefore passed and kept in position for three days during mandelic acid treatment. Case 20 had had mandelic acid treatment at home once before and relapsed; she

## SUMMARY OF CASES

No.	Sex and age.	Organism.	Diagnosis.	Duration of infection.	Days till urine sterile.	Remarks.
1	F. 48	<i>B. coli.</i>	C. pyelitis.	2 years.	7 days.	Hypertension. Granular and hyaline casts.
2	F. 30	"	"	1½ "	6 "	Could not take ketogenic diet.
3	F. 26	"	Pyelitis and nephritis.	5 weeks.	10 "	Subacute nephritis not affected by mandelic acid.
4	M. 53	"	C. pyelitis.	1 year.	Not sterile.	? Prostatic calculi but no prostatic enlargement. Feels better on mandelic acid.
5	F. 49	"	"	?	3 weeks.	—
6	F. 34	"	"	2 years.	7 days.	—
7	M. 28	"	A. pyelitis.	—	14 "	Urine showed few hyaline and granular casts.
8	F. 5	"	C. pyelitis.	6 months.	4 "	Relapse after successful ketogenic diet.
9	F. 30	<i>B. coli</i> T.B.	T.B. kidney and bladder.	6 "	Not sterile.	No effect on secondary infection; refuses to take ammonium chloride.
10	M. 52	<i>B. coli.</i>	A. pyelitis.	4 days.	4 days.	—
11	F. 59	<i>B. coli</i> staph.	Pyelitis and cystitis.	6 weeks.	Not sterile.	Had subacute combined degeneration.
12	F. 30	<i>B. proteus.</i> <i>B. coli.</i>	C. pyelitis.	3 years.	"	Renal insufficiency.
13	F. 50	"	A. pyelitis.	1 month.	5 days.	Relapse and cure in 10 days.
14	F. 25	"	"	1 week.	10 "	—
15	F. 35	"	C. pyelitis.	Many years.	7 "	Mandelic acid made her sick and she refused it. Urine sterile but symptoms not improved.
16	M. 50	"	Pyonephrosis and perinephric abscess.	?	Not sterile.	Died of <i>B. coli</i> septicaemia.
17	M. 64	"	C. pyelitis.	3 months.	10 days.	Cure, later relapsed.
18	F. 14	"	"	1 year.	3 "	Kidney drained with catheter.
19	F. 45	"	A. pyelitis.	24 days.	2 "	—
20	F. 30	"	C. pyelitis.	9 months.	14 "	Previous attack cured in 14 days by mandelic acid.
21	F. 31	"	"	6 "	12 "	—
22	F. 21	"	"	5 weeks.	14 "	Followed pregnancy.
23	F. 27	"	Pyelitis of pregnancy.	3 "	21 "	—
24	F. 37	"	C. pyelitis.	10 "	14 "	—
25	F. 21	"	A. pyelitis.	4 "	10 "	—
*26	M. 66	"	C. pyelitis.	11 years.	5 "	—
*27	F. 6	"	Pyelitis and nephritis.	?	5 "	Acute nephritis, improved during treatment.
*28	F. 53	"	C. pyelitis.	Many years.	4 "	—
*29	F. 35	"	"	Few years.	7 "	Ammonium chloride and ammonium mandelate.

\* Treated with ammonium mandelate. C. = chronic; A. = acute.

had a history of having had "cystitis" at the age of 13 years. In Cases 7, 13, 19, 22, 23, and 25 a recent acute pyelonephritis had been controlled by alkaline treatment, but a heavy infection still remained. Cases 10 and 14 were treated with mandelic acid in the acute stage.

## AMMONIUM MANDELATE

The only disadvantage of mandelic acid treatment as so far practised is the necessity of giving two somewhat unpleasant medicaments, one followed closely by the other, four times in the day. The ammonium chloride is particularly nauseous to some patients and may actually cause vomiting, and even when it is given in capsule form there may be an unpleasant after-taste.

Mandelic acid has to be given as a salt because the acid itself is a gastric irritant. The ammonium chloride is given to acidify the urine so that a proportion of the mandelate administered is excreted as mandelic acid.

To obviate these disadvantages if possible, the British Drug Houses Ltd. have prepared the ammonium salt of mandelic acid, and we are indebted to them for placing stocks at our disposal for clinical trial. They state that ammonium mandelate, being

hygroscopic, cannot be supplied in tablet form and they have therefore made it up as an elixir, 1 oz. of which contains 34 grains of the salt, equivalent to 30 grains (2 grammes) of mandelic acid.

Salts such as ammonium chloride act as acids in the body owing to the ammonium radicle being converted into urea, and leaving the acid radicle to be excreted. Ammonium mandelate should be weaker in its action than ammonium chloride, but on the other hand the use of ammonium mandelate dispenses with the necessity of giving the sodium salt, and so saves the addition of an unnecessary alkali. Based on molecular weights, 3.0 grammes of sodium mandelate plus 1.0 gramme of ammonium chloride (approximately the usual doses) should be roughly equivalent to the effect of 3.0 g. of ammonium mandelate administered by itself.

It seems likely that, provided the urine can be sufficiently acidified by ammonium mandelate alone, the bacteriostatic effect of the mandelic acid radicle will be as good as when the sodium salt is used. We therefore tried the acidifying effect of the elixir of ammonium mandelate on ourselves (it is not particularly unpleasant to take) and found that doses of 34 grains of ammonium mandelate four times daily produced a satisfactory urinary acidity (pH 5.3)

within an hour or two, but this degree of acidity was not invariably maintained throughout the day. As we are both of about average weight (10 st. 2 lb. and 10 st. 9 lb.) we concluded that somewhat larger doses should generally be given for the treatment of patients.

Four patients were treated with ammonium mandelate, and in all four a sterile urine was effected in a week or less, though all had a chronic infection. Case 26, a man of 13 st., required doses of 51 grains four times daily (1½ oz. of the elixir). Case 27, a child of 6 (weight 3 st. 7 lb.) with acute nephritis as well as *B. coli* infection, was given 17 grains four times daily. Case 28 had 34-grain doses. In Case 29 the urine was alkaline to litmus before treatment, and 51-grain doses supplemented by 30 grains of ammonium chloride were necessary to produce a satisfactory acidity and cure the infection.

In the light of this short experience, together with what is already known of mandelic acid treatment, we feel justified in saying that ammonium mandelate, suitably prepared, is a convenient means of administering mandelic acid, and that in the majority of cases the use of ammonium chloride can thereby be obviated. The suitable dose of ammonium mandelate is probably the same as that of the sodium salt—namely, about 50 grains four times in the day, the equivalent of about 3 grammes of mandelic acid.

#### TREATMENT OF PYELONEPHRITIS IN GENERAL

The disease "pyelitis" affecting, as it does, the parenchyma of the kidney as well as the renal pelvis, ureter, and bladder, is better known as pyelonephritis. The term cystitis may be restricted to the occasional infection of the bladder only, by catheter or otherwise, before an ascending spread has taken place.

Acute pyelonephritis is often associated with high temperature, rigors, and general symptoms of which severe headache is one of the most frequent. For such severe cases, alkalis if given in sufficient doses are so efficient in bringing down the temperature and controlling the distressing symptoms that we have not used mandelic acid therapy, fearing to cause a temporary exacerbation of symptoms or to induce vomiting. It should be noted that it is often necessary to give as much as 30 grains of potassium citrate and 30 grains of sodium bicarbonate every two hours in order to produce the effect. We have recently seen two patients in whom the pyrexia remained *despite an alkaline urine*, until the dosage was pushed to this extent.

When the acute stage has been controlled, a few cases rapidly clear up spontaneously, especially in women after delivery. In many more, however, pus cells and bacilli remain in the urine, and a chronic pyelonephritis develops. Often there are acute exacerbations and for years the patient suffers from poor health and has intermittent attacks of frequency, dysuria, pyrexia, or urticaria. A few eventually develop renal failure.

As nearly all these chronic infections are now avoidable, we would like to stress the importance of not discharging any case of pyelonephritis, especially when acute, until it is known that the urine is sterile. If, after an acute attack has settled down, bacilli are still present, mandelic acid therapy should be employed at once, before waiting for chronic changes to develop.

For those who show a marked tendency to recurrence we are trying the effect of giving two consecutive days of mandelic acid treatment in each month. Between these brief courses, fluid intake should be

liberal, and both constipation and the over-use of aperients should be avoided as far as possible.

#### SUMMARY

Of 29 cases of urinary infection treated with mandelic acid 24 showed sterile urine within 2–21 days. Of the successful cases 2 had also a concurrent nephritis in an active stage, which was not adversely affected by the treatment. Of the 5 failures at least 3 were unsuitable cases in which cure was not to be anticipated.

Ammonium mandelate was found to be as effective as the sodium salt, and when it was used it was usually unnecessary to give the unpleasant ammonium chloride.

The proper use of these remedies will prevent chronic pyelonephritis.

## X RAY APPEARANCES OF THE LUNGS OF ELECTRIC ARC WELDERS

By A. T. DOIG, M.B. St. And., D.P.H.

MEDICAL SUPERINTENDENT, OAKWOOD HALL SANATORIUM, ROTHERHAM; AND

A. I. G. MCLAUGHLIN, M.B. Sydney,

M.R.C.P. Lond.

H.M. MEDICAL INSPECTOR OF FACTORIES, HOME OFFICE

(WITH ILLUSTRATIONS ON PLATE)

ATTENTION has been directed recently to the acute pulmonary conditions which may occur in welders as a result of their occupation. Adler-Herzmark<sup>1</sup> in 1929 described the illness and death of an electric arc welder from pulmonary oedema which he attributed to nitrous fumes. In 1934 Bridge<sup>2a</sup> recorded a number of cases of acute poisoning by nitrous fumes occurring in oxy-acetylene welders who were working in a confined space in a ship. Williman's recent case<sup>3</sup> of acute fatal pneumonia in an electric arc welder was that of a man who had been welding galvanised iron in a confined space; and Titus, Warren, and Drinker<sup>4</sup> have shown after a series of animal experiments that the pulmonary oedema associated with welding (not necessarily of galvanised metal) in confined spaces is caused by the gases (nitrogen peroxide and ozone) generated at the electric arc and not by the fine particles of iron oxide found in the fume. The symptoms associated with the welding of galvanised metal appear to be comparable with those of metal fume fever and were described by Bridge<sup>2b</sup> in 1921, by Koelsch in 1923,<sup>5</sup> and also by Drinker<sup>6</sup> and his co-workers in 1927. Similar symptoms in welders working on galvanised metal have been noted by Dickson<sup>7</sup> and by Anderson.<sup>8</sup> Metal fume fever is a transient malady and is characterised mainly by malaise, pyrexia, and shivering attacks.

Some of the occupational risks in welding—e.g., metal fume fever and poisoning by nitrous fumes—are common to both electric arc and oxy-acetylene welding, but each method has its proper risks. Wirtschaffter and Schwartz<sup>9</sup> state that the oxy-acetylene welder is exposed, under various working conditions, to poisoning by the products of incomplete combustion of the oxy-acetylene flame, especially

carbon monoxide and acetylene, and also by impurities in commercial acetylene. Westhofen,<sup>10</sup> who made a statistical study of the health of 146 electric arc welders, shows that a large number of them suffer from colds and inflammatory conditions of the upper respiratory tracts, a fact which he believes can be explained by the irritating properties of the metal fume and by the sudden changes of temperature to which welders are exposed.

Chronic pulmonary lesions directly associated with the occupation have not been recorded up to the present time as occurring in electric arc welders. This fact is not surprising because the process is a comparatively new one and it is only during the last ten years that it has been widely adopted. It may be noted also that covered electrodes have only been used for about ten years. We present in this paper the results of a clinical and radiological examination of the chests of 16 electric arc welders. They are apparently healthy men and are actively engaged at their occupation. Nearly all of them are young men who were apprenticed to electric welding at 14 years of age and who have worked at no other trade. The X ray films of 6 of them show a generalised fine mottling over both lung fields; the remaining films show less marked changes, but none could be considered to be a picture of a completely normal chest. The conditions which have to be considered in the differential diagnosis include miliary tuberculosis, asbestosis, silicosis, and other pulmonary conditions caused by dust or fumes. The X ray film in the first case, in view of the family history, was for some time thought to be an example of miliary tuberculosis. In the present early stage of the investigation we are not prepared to be dogmatic about the interpretation of the radiographic and clinical findings, especially because no opportunity for histological examination of the lungs has arisen. In this paper we merely wish to record the results of our examinations as far as they have gone and to discuss in a general way the possible factors in the aetiology.

#### THE FIRST TWO CASES

**CASE 1.**—Aged 44. This man was seen by one of us (A. T. D.) at the Rotherham Tuberculosis Dispensary on June 28th, 1933, because his sputum had been stained slightly with blood for a few days. He felt well except for slight debility which had followed an attack of influenza six months previously.

*Family History.*—His father and grandfather, both of whom had been tin miners in Cornwall, had died from silicosis.

*Occupational History.*—He left school at 14 years of age and for 1 year stoked boilers in a clay mine (above ground). For 18 years (until 1925) he worked as a blacksmith, but during this time he had done occasional electric welding jobs. He has been an electric arc welder for 11 years.

*X Ray and Other Examinations.*—On June 28th, 1933, an X ray film showed fine mottling\* evenly distributed over both lung fields. The sputum was examined on July 4th, 1935, for tubercle bacilli and for asbestos bodies, with negative results. The glass shield used by the man to protect his eyes during electric welding was examined on Sept. 29th, 1933, at the Government laboratory. The report stated that "the fume deposited on the glass consists essentially of magnetic iron oxide ( $Fe_3O_4$ ). Slight evidence of the presence of silica was obtained but this was probably derived from the glass slide, the surface of which was damaged by red-hot particles thrown off from the electrodes." Further X ray films were taken of his chest on Dec. 26th, 1933, and also on Sept. 3rd, 1934

\* We have used the word "nodule" as a convenient term to describe the individual shadows without reference to their size. "Stippling" is used to indicate the very fine "nodulation" seen in several cases, whereas "mottling" is used to describe a coarser type of "nodulation."

(Fig. I. on Plate). The appearances differed in no essential point from those of the original film. It was thought however that the punctate shadows seen in the later film were slightly larger, especially in the fifth right costal space close to the hilum.

The patient has not lost any time from work and when seen recently was found to be in fairly good health. Since 1933 he has been wearing a mask over his nose and mouth during actual work at electric welding. Physical examination revealed few abnormal signs with the exception that the breath sounds were harsh over the apices and bases of the lungs, and that a few post-tussic crepitations could be heard at both bases. The movement of the chest was equal on both sides but the degree of expansion was somewhat limited.

**CASE 2.**—Aged 35. This man was asked to attend for X ray examination because of the nature of his work. His occupational history shows that after leaving school he worked in an office for 6 years; for another 3 years he was engaged in a steel works as a cold steel roller, and for the 11 years he has been working continuously as an electric arc welder. For the last year he has been working as storekeeper because he thought the fume from welding was affecting his health. There is no family history of tuberculosis. He has a slight cough and occasional morning sputum, but otherwise is in good health. He was first radiographed in September, 1934, the film (Fig. II. on Plate) showing features similar to those of Case 1. The lung fields generally show a fine mottling, the individual shadows being irregular in size and having soft outlines. The mottling is distributed fairly uniformly, although the upper two-thirds of each lung field are rather more affected than the lower thirds. Both lungs are equally affected. A recent radiogram of the chest (Jan. 6th, 1936), taken a year after he had given up electric welding, shows that the mottling noted in the first film is still present but less marked. In some of the larger nodules a minute central core is visible. Clinical examination of the chest shows that the expansion is equal on both sides but is rather less than normal. The percussion note is not impaired, and the breath sounds are harsh with prolongation of expiration over both lower zones, especially in the mid-axillary lines. Post-tussic crepitations are heard at both bases. Examination of the sputum (March 12th, 1936) shows that it contains large numbers of macrophages or dust cells which are packed with fine granules of iron oxide. No asbestos bodies are seen.

On account of the findings in the first 2 cases, 14 more welders were asked to attend for examination. Brief notes of the history and of the results of the X ray examinations of the chest are given. In a few cases the results of clinical examination of the chest have been added.

#### FOUR "POSITIVE" CASES

Four showed X ray appearances comparable with those seen in the first 2 cases, and are therefore classed as *positive*.

**CASE 3.**—Aged 25. Electric arc welder for 9 years. No other occupation. No family history of tuberculosis. Has a slight cough with copious black sputum, especially after welding inside tanks. Movement diminished over the left upper part of the chest. No impairment of percussion note. Breath sounds harsh over left upper region and also at both bases posteriorly. Crepitations were heard at both bases in the axillary lines but more clearly on the left side. *Radiography* (Jan. 6th, 1936). Skeleton, heart, and diaphragm normal. Shadow of lung roots not enlarged. Prominent (? calcified) opacity in the upper pole of left root. Fine bronchial ramifications slightly accentuated generally. Fine stippling throughout both lung fields, the nodules being irregular in size and shape. The stippling is slightly more marked in the upper half of the right lung.

**CASE 4.**—Aged 23. Electric welder for 7 years. Health good and no family history of tuberculosis. Slight cough with morning sputum. *Radiography* (Jan. 8th, 1936). Skeleton, heart, and diaphragm normal. The shadow of the right hilum is definitely enlarged. The

bronchial markings are not increased. Over both lung fields there is generalised stippling. The nodules are irregular in size and shape and consist of single and aggregated units. Their outlines are soft but some of the larger ones have a hard central core.

CASE 5.—Aged 26. Electric arc welder for 9 years. Had an attack of acute bronchitis 5½ years ago, since when has had a persistent cough with black sputum. *Radiography* (Jan. 8th, 1936). Skeleton, heart, and diaphragm normal. Bronchial markings prominent. Right lung clear. Over the upper half of the left lung fine stippling is seen. Both hilar regions normal.

CASE 6.—Aged 28. Electric arc welder for 12 years. Health good. No symptoms apart from slight cough and sputum. Examination of the chest shows that the expansion is good and equal. Percussion note good. Breath sounds well transmitted with a slight prolongation of the respiratory murmur. No adventitious sounds. Heart sounds normal. *Radiography* (Jan. 15th, 1936). Skeleton, heart, and diaphragm normal. Right interlobar septum visible. Generalised fine stippling throughout both lung fields, the shadows being irregular in size and having soft margins.

### THREE "SUSPICIOUS" CASES

Three more cases showed X ray changes which were not so definite as those presented by the first 6 cases. We have classified them as *suspicious*.

CASE 7.—Aged 26. Electric arc welder for 9 years. No other occupation. No family history of tuberculosis. Has had a cough with morning sputum on and off for 10 years. The cough is worse after he has done a welding job in an enclosed space, and the sputum then becomes black. Finds that he gets very tired, especially on night shifts. *Radiography* (Jan. 6th, 1936). Skeleton, heart, and diaphragm normal. The bronchial shadows are accentuated generally in both lung fields. There is fine stippling distributed over the left upper zone, especially in the area immediately surrounding the upper pole of the left root.

CASE 8.—Aged 25. Electric arc welding for 11 years. No family history of tuberculosis. Has only a slight cough which is worse after working in an enclosed space, and brings up a certain amount of black sputum mainly in the mornings. Examination of the chest revealed no abnormal physical signs. *Radiography* (Jan. 6th, 1936). Skeleton and heart normal. Right dome of diaphragm slightly blurred. Slight enlargement of the hila, especially on the left side. There is only a slight increase in the bronchial trunk shadows, but the fine bronchial ramifications, especially in the mid-zones, present a honey-combed appearance. A few faint soft and fairly coarse nodules are present in both lung fields. These are mainly situated peripherally and give a coarse mottled effect. The mottling in this case is not nearly so well marked, nor the nodules so fine as in the definitely positive cases.

CASE 9.—Aged 22. Electric arc welder for 8 years. Health good, and only has a cough after doing welding inside a tank. *Radiography* (Jan. 8th, 1936). Skeleton, heart, and diaphragm normal. Bronchial shadowing is prominent in the right upper lobe, and some calcified nodules are present in the right hilum and upper perihilar area. Fine bronchial ramifications are increased generally, and both lung fields have a slightly stippled appearance, the nodules being poorly defined and well spaced. Actual nodulation is however present.

### "RADIOGRAPHICALLY NEGATIVE" CASES

The remaining 7 cases have been classified as negative from a radiological point of view. It will be seen however that a number of the films showed increased bronchial striation or fine honeycombing as opposed to definite mottling, and could not strictly be called normal X ray films of the chest.

CASE 10.—Aged 41. Oxy-acetylene welder for 3 years during his apprenticeship, and electric arc welder for 17 years. No family history of tuberculosis. Had a slight attack of influenza 2 years ago which kept him

away from work for a week. Has a slight cough with morning sputum. *Radiography* (July 13th, 1934). Heart rather bulbous and slightly enlarged to the right. The right dome of the diaphragm is elevated, and the right costophrenic angle obliterated. The shadow of the left hilum is enlarged. The bronchial trunks in both lungs are markedly accentuated. Close examination reveals a suggestion of fine stippling in the upper lung fields, but this feature is not definite.

CASE 11.—Aged 23. Electric arc welder for 9 years. Health good and no family history of tuberculosis. Has no symptoms. *Radiography* (Jan. 8th, 1936). Skeleton, heart, and diaphragm normal. Right interlobar septum very faintly seen. Fine bronchial ramifications show a slight honeycombing but no definite nodulation. An appearance of nodulation is present, especially in the third and fourth right intercostal spaces as a result of the crossings of the fine bronchial ramifications.

CASE 12.—Aged 25. Has been an electric arc welder for 10 years. He attended the dispensary because his wife was suffering from open pulmonary tuberculosis. Has no cough or sputum. *Radiography* (March 18th, 1935). Skeleton, heart (small), and diaphragm normal. Bronchial shadows not definitely increased in the lower zones. A slight degree of stippling is present in the second right intercostal space and also in the second and third left intercostal spaces.

CASE 13.—Aged 23. Electric arc welder for 8½ years. No other occupation. No family history of tuberculosis. Has no cough as a rule, but brings up black sputum after doing electric welding inside tanks or boilers. *Radiography* (Dec. 23rd, 1935). Skeleton, heart, and diaphragm normal. Bronchial markings generally intensified. No definite stippling present. In certain areas—e.g., the fifth right and fifth left intercostal spaces—the lung parenchyma shows a fine "honeycombing."

CASE 14.—Aged 31. Electric arc welder for 3½ years. Health good. No symptoms. No family history of pulmonary tuberculosis. Examination of the chest shows no abnormal signs. *Radiography* (Jan. 15th, 1936). Skeleton normal. Left auricular region of the heart shadow appears to be enlarged. Increased bronchial striation but no parenchymatous mottling.

CASE 15.—Aged 27. Electric arc welder for 11 years. Health good. Slight cough and sputum. Examination of the chest reveals no abnormal physical signs. *Radiography* (Jan. 15th, 1936). Skeleton, heart, and diaphragm normal. Slight increase of bronchial markings but no parenchymatous stippling.

CASE 16.—Aged 32. Electric arc welder for 9 years. Health good. Slight cough and sputum. Clinical examination showed no abnormal physical signs. *Radiography* (Jan. 15th, 1936). Skeleton, heart, and diaphragm normal. Definite increase of bronchial striation with very slight fine honeycombing but no definite stippling of the lung parenchyma.

### DISCUSSION

The diagnosis of the underlying pulmonary lesions which have given rise to these striking X ray changes is a matter which is both interesting, and in the absence of histological examination of the lung tissue, highly speculative. Little doubt exists, however, that the lung changes have been brought about in these men by the dust or fume which they have inhaled while working as welders. During welding operations dense white or greyish-white fume rises up continuously from the spot which is being welded. The welder is obliged to bend closely over his work because he holds in front of his face a coloured glass screen which protects his eyes from the strong light but impedes his vision. If no protective measures are adopted, the welder cannot fail to inhale large quantities of fume during the time he is actually working.

The electrodes or welding rods which contain a core of metal and an outer covering are consumed

gradually by the heat generated (about 1500° C.) during the welding operation. The metal in the core of the rod becomes molten and, assisted by the flux contained in the covering, spreads over the surface of the metal which is being welded. The fume is therefore made up of the volatilised constituents of the coverings of the rods together with fine particles of oxidised metal, usually in the form of iron oxides. In addition the fumes probably contain gases such as nitrogen peroxide and ozone which are formed by the action of an electric spark on the air. The composition of the coverings of the electrodes or welding rods becomes, in the circumstances, a matter of some importance. Many substances, all of which we do not propose to enumerate, are used. The basis of the majority of the coverings is sodium silicate which acts as a flux. Again, the coverings of a certain type of electrode contain asbestos. The rods are sometimes dipped in a mixture containing powdered asbestos and sodium silicate, or asbestos yarn is wound round the rod and fixed by sodium silicate. In some cases the asbestos completely covers the rods, and in others it is merely a cord which is wound spirally about the rod.

The composition of the fumes arising from electric welding electrodes has not yet been fully investigated. Mr. L. C. McNair, H.M. Engineering Inspector of Factories, has however had partial analysis made of the fumes evolved from an asbestos-covered electrode and some asbestos fibres were found. When the particulate matter of the fumes was collected in an Owen's dust-counter, it was seen that a large proportion consisted of iron oxide particles, with an occasional asbestos fibre.

The X ray appearances in the well-marked cases differ from the usual picture of asbestosis. In none of the positive cases and in only one of the suspicious cases was there any blurring of the diaphragmatic shadow, and in no case was the heart outline blurred. The line of the interlobar septum (a feature present in a number of films of cases of asbestosis) is seen in only one positive case. The opacities in the films are not accentuated at the bases of the lungs, but on the contrary the upper lung fields appear to be the earliest, and in established cases, most markedly affected. Before asbestosis can be eliminated from the differential diagnosis it must be remembered that the asbestos fibres are being subjected to intense heat and are not in the same physical state as the fibres which are inhaled by workers in an asbestos factory. It is possible that an atypical picture of asbestosis might be produced by the inhalation of altered asbestos. Merewether<sup>11</sup> says that—

"the radiographic appearances of the developed or advanced stages of asbestosis are distinctive, although they are not specific. While, as is the case with silicosis, certain radiographic appearances may be looked upon as typical of the disease, frequently modifications of and departure from the typical picture occur." †

The X ray appearances in our cases most closely resemble those of a fine silicosis, but the clinical features show two important differences. In the first place, the electric welders whom we examined are all in good health and are fit to work. The only symptoms observed were slight cough and morning expectoration, and in the first case a small hæmoptysis occurred. This man has not been away from work even for a day since he was first seen in June, 1933,

† We have submitted our films to Dr. Merewether and he is of the opinion that "while some of the films give a general impression of asbestosis, further examination reveals so many points of difference in detail from the currently accepted radiographic appearance of asbestosis, as to negative such a diagnosis."

## DESCRIPTIONS OF ILLUSTRATIONS ON COLOURED PLATE

DR. MANSON-BAHR

- A.—ACUTE BACILLARY DYSENTERY. Shiga's bacillus isolated. General œdema of mucosa, spasm, sub-mucous hæmorrhages. Early healing stage.
- B.—CHRONIC BACILLARY DYSENTERY. Flexner-Y infection. Agglutination test positive to Flexner 1:180. Great improvement on intestinal lavage.
- C.—AMÆBIC ULCERATION of lower rectum giving rise to symptoms suggestive of carcinoma.
- D.—AMÆBIC DYSENTERY. Chronic stage, showing "pitting" of mucous membrane.
- E.—ACUTE AMÆBIC DYSENTERY. Active ulceration of mucosa with blood and mucus exudate.
- F.—INTESTINAL BILHARZIASIS. Early stage. Patches of granulation tissue containing eggs of *Bilharzia mansoni*.
- G.—MUCOUS COLITIS. Showing the pale colour of the mucosa and the masses of adherent mucus.
- H.—ACUTE ULCERATIVE COLITIS. First stage. Usually called hæmorrhagic colitis.
- I.—ACUTE ULCERATIVE COLITIS. Showing plum-coloured, easily traumatised, mucosa in the second stage.
- J.—ACUTE ULCERATIVE COLITIS. Early stage, showing granular mucosa, with purulent exudate covering the surface. Note the lack of normal folding of the mucosa.
- K.—ULCERATIVE COLITIS. Superficial ulceration in the third, or ulcerative stage.
- L.—TUBERCULOUS ULCERATION OF RECTUM. Case in which tubercle bacilli were found in material obtained through the sigmoidoscope. The patient was suffering from chronic diarrhœa with blood and mucus in the stools.

and his health at the present time is good. None of the men suffers from dyspnoea. Secondly none of them has concomitant pulmonary tuberculosis.

Miliary tuberculosis can be ruled out of the differential diagnosis for clinical reasons, and to some extent on the radiological appearances. None of the cases shows the dyspnoea, cyanosis, and tachycardia of acute or subacute miliary tuberculosis. Chronic or healed miliary tuberculosis is rare and it is difficult to imagine that a condition of such rarity would be found in 6 out of one group of 16 men. In the X ray films of the welders' chests (see Plate) the fine opacities are irregular in size and shape, whereas in miliary tuberculosis of the lung the shadows are more uniform.

A further possible explanation of the X ray appearances in this series of cases is that the inhalation of small quantities of nitrous fumes together with the superadded effect of fine iron oxide dust might set up small areas of chronic inflammatory change, congestion, or fibrosis in the lungs. Again, the iron oxide particles might be opaque to the X rays and produce the picture without the associated presence of fibrosis and congestion.

### SUMMARY

1. The chests of 16 electric arc welders who have been engaged at the trade for periods varying from 6–16 years have been examined radiologically.
2. In 6 cases the X ray films showed fine nodulation over both lung fields; in 3 cases stippling was present over a more limited area; the remaining cases showed varying degrees of accentuation of the bronchial shadows, but no stippling. In no case was a completely normal radiogram obtained.
3. Clinical examination of the chests revealed few abnormal signs.
4. The alterations in the pulmonary or bronchial tissues underlying these X ray changes have been

(WITH ILLUSTRATIONS ON PLATE)

THE discovery that the continued administration of oestrone, subcutaneously, led to squamous metaplasia of the uterine epithelium of castrate female rats<sup>1</sup> has been confirmed and extended by further experiments reported elsewhere<sup>2</sup> in which treatment was continued for periods up to 132 days. It

is the purpose of this communication to record the results of experiments of even longer duration. Cramer and Horning<sup>3</sup> have reported the appearance of hæmorrhagic chromophobe adenomata of the anterior pituitary in 3 male mice of a series of 12 receiving external applications of oestrone dissolved in chloroform for prolonged periods, up to 44 weeks; many of their animals showed cachexia, atrophy of the spleen and thymus, and degenerative changes in the adrenal cortex—effects which they ascribe in part to hypopituitarism. Simple enlargement of the pituitary was observed in 8 of their series of 12. It is known that the administration of large doses of oestrin to female rats may lead to hypertrophy of the anterior lobe within a few days,<sup>4</sup> and that this is accompanied by enlargement, probably secondary, of the adrenal cortex; but these changes were much less marked in males or in castrates.

**FIG. I.**—Transverse section across the uterus of oestrin-treated rat. Note the enormous development of fibrous tissue in the submucosa which leads to partial obliteration of the uterine cavity. The epithelium shows no metaplasia in this case.

Six castrate female rats, initially 3-4 months old, received daily subcutaneous injections of 30 γ of oestrone, dissolved in corn oil, for 331 days; vaginal oestrus was maintained, with very rare lapses, throughout this period. The animals were sacrificed after a further 30 days, during which all (save one) were either left untreated or were injected with solutions of crystalline progesterone (corpus luteum hormone), and in either case had returned more or less rapidly to an anoestrus state. The progesterone-treated animals did not differ materially from those in which all treatment had been discontinued.

At post-mortem examination the horns of the uteri were found to be nearly solid, pearly white, and hard; histological study revealed an extreme hypertrophic fibrosis, pushing the mucosa and muscular coats aside and enlarging the volume of the organ (Fig. I.). Squamous metaplasia of the epithelium was present in five cases (Fig. II. on Plate). These alterations in the uteri were also observed in biopsy specimens taken between the 300th and 330th day of treatment; occlusion of the cervix with secondary pyometrium was not encountered in this series.

The pituitaries were enlarged in all cases, and large cavernous adenomata of the anterior lobe were present in three; one showed a small adenoma of the intermediate lobe, and vacuolisation of the posterior lobe was noted several times. In one case

two adenomata were observed in the anterior lobe of the same rat (Fig. III., and Fig. IV. on Plate). All showed multiple mammary milk cysts (Fig. VII.);

FIG. III.—Macroscopic picture of a large pituitary tumour in an oestrin-treated rat.

while other breast changes observed included an adenofibroma, whose scirrhus tissue invaded the spaces between the fibres of the pectoral muscle (Fig. VIII. on Plate). The adrenals were enlarged in five cases, and in one of these a cystic adenoma of the cortex was found on the left side (Fig. IX.); in the rat which received oestrin treatment up to the day when it was killed, however, cortical atrophy, hæmorrhages, and cysts were evident.

Five male rats, two of which were castrated during the experiment, received similar daily injections of oestrone for periods up to 344 days. As in a previous experiment,<sup>2</sup> the testes, penis, seminal vesicles, and prostate showed marked atrophy, but metaplasia and keratinisation were not observed. The pituitaries were enlarged in all cases, and in two (one normal,

FIG. VII.—Milk cysts in the mammary gland of an oestrin-treated rat.

one castrate) cavernous adenomata were discovered in the anterior lobe.

The animals selected for these experiments were taken at random from stock cages containing 20-50 rats each, which in turn are filled haphazard from

the litter cages; the colony consists of some 6000 animals, and breeding is conducted without segregation of families; it is therefore improbable that all those which developed pituitary tumours, for instance, were of one litter or otherwise closely related. It is therefore unlikely that hereditary factors could have played an important part in producing the changes described. The incidence of

FIG. IX.—Cystic adenoma in the adrenal cortex of an oestrin-treated rat.

spontaneous tumours of any kind is very low in this colony.

This work was made possible by the generous support of Sir Charles Lindsay of Montreal. We are also indebted to Dr. A. Girard of Paris for supplying the oestrone; to Miss J. E. Williamson for technical assistance; and to Dr. J. S. L. Browne for preparing the progesterone.

### TUMOUR OF THE PITUITARY INDUCED WITH FOLLICULAR HORMONE

BY Prof. BERNHARD ZONDEK

(From the Gynaecological and Obstetrical Department of the Rothschild-Hadassah Hospital, Jerusalem)

As I reported a short while ago in *THE LANCET*,<sup>1</sup> the function of the anterior pituitary gland may be inhibited by administering large doses of oestrin over a long period of time. Both the growth hormone of the anterior lobe and the gonadotropic hormones are put out of action by the follicular hormone, so that experimental animals (rats) show inhibition of growth and atrophy of the gonads. In this way dwarfed animals with atrophic genitals are produced. I intended to describe in later reports the effect on other endocrine glands and on the anterior lobe of the pituitary itself. Meanwhile an article by W. Cramer and E. S. Horning<sup>2</sup> appeared four weeks

after my paper. The authors investigated the carcinogenic effect of oestrin by painting the skin of mice twice weekly with a 0.01 per cent. oestrin solution ( $\alpha$ -folliculin) in chloroform. They studied the pituitary in twelve mice, which were treated over a prolonged period. Only one gland was normal to the naked eye; eight were macroscopically enlarged without an alteration in the general shape and without gross pathological lesions in the gland; and three were definite adenomatous tumours—nodular, round, deeply congested, and hæmorrhagic. In one case the tumour extended over the optic nerves and compressed them, producing degenerative changes; the authors described the tumour as a hæmorrhagic chromophobe adenoma of the anterior lobe. They believe that they have experimentally produced the syndrome of a disease known in man as Simmonds's disease (cachexia hypophysipriva).

## EFFECT OF OESTRIN ON THE PITUITARY

In the following I wish to report, as I mentioned in my last paper, my findings in the pituitary of animals whose growth was inhibited by the administration of follicular hormone.

TABLE I

Weight of the Pituitary and Body-weight in Male Rats

(a) CONTROL ANIMALS

Number.	Duration of expt. (weeks).	Medication.	Body-weight (g.).	Weight of pituitary (mg.).
R 319 ..	14	Olive oil.	104	7.0
R 251 ..	16		160	11.4
R 279 ..	17		125	8.2
R 281 ..	18		160	13.6
R 250 ..	19		160	8.4
Average ..	16.8	—	141.8	9.7

(b) EXPERIMENTAL ANIMALS

(c) Number. (d) Corresponding control animal.	Duration of expt. (weeks).	(e) Dose folliculin-menformon (M.U.) twice weekly. (f) Total dose.	Body-weight (g.).	Weight of pituitary (mg.).	Increase of weight (%).
(c) R 323 (d) R 319	14	(e) 5,000 (f) 140,000	70	9.0	23.6
(c) R 253 (d) R 251	16	(e) 10,000 (f) 320,000	100	43.1	273.9
(c) R 285 (d) R 279	17	(e) 10,000 (f) 340,000	95	16.1	96.3
(c) R 284 (d) R 281	18	(e) 5,000 (f) 180,000	100	20.6	51.4
(c) R 252 (d) R 250	19	(e) 5,000 (f) 180,000	95	41.6	395.2
Average	16.8	(f) 232,000	92	26.08	170.08

Whereas the gonads (ovaries and testes) of the animals undergo complete atrophy, the pituitary is enlarged. It is interesting to note, however, that an increase in the weight of the pituitary—i.e., of the anterior lobe—was not found in all animals. There is also a characteristic difference between the sexes. After prolonged treatment with follicular hormone,\* the pituitary of male rats shows enlargement in all cases, while the pituitaries of the females

are macroscopically unaltered. Table I. shows that while the weight of the pituitaries in male controls varies from 7.0 to 13.6 mg., with an average of 9.7 mg., those of male rats after folliculin treatment lasting from 14–19 weeks weigh from 9.0 to 41.6 mg., with an average of 26 mg. Comparing each animal with its individual control (Table I.) there was in every case an enlargement of the pituitary, the increase in its weight varying from 29 to 395 per cent. The body-weight therefore decreases by an average of about 30 per cent., the pituitary enlarges by an average of 170 per cent.

The results in female rats are quite different, though they also display stunting of the body growth. After treatment for 15 weeks—5000 M.U. (mouse units) of folliculin twice weekly—the body-weight of the treated animal is 33 per cent. less than that of the controls. However, there are no marked differences in the weight of the pituitary. The pituitaries of the controls weigh 10.9 mg. on an average, the pituitaries of the treated animals 12 mg. The period of treatment lasted in male and female animals 16 weeks on an average.

These experiments show that the functional inhibition of the anterior lobe of the pituitary—i.e., the production of stunted growth and atrophic genitals—appears equally in male and female animals, but that the reaction of the pituitary itself differs in the two sexes. The growth of the anterior lobe itself

Left: Brain of control rat (R 233), showing normal pituitary. Right: (R. 228). Tumour of the pituitary, after receiving 280,000 M.U. dimenformon.

cannot be held responsible for the defect in pituitary function because the growth hormone and the gonadotropic hormones are also diminished in females whose pituitaries are not enlarged. It is not the enlargement of the pituitary and the formation of a tumour which causes the syndrome of hypopituitarism—as is claimed by Cramer and Hörning—because, if it did, the hormone would not inhibit the function of the pituitary in female animals.

Why the male pituitary reacts by enlargement while the female pituitary does not do so cannot be explained. It may be mentioned that Collip<sup>3</sup> and Evans<sup>4</sup> were able to produce considerable enlargement of the anterior lobe of the pituitary in female animals, but not in males, by prolonged treatment

\* I am indebted to the Organon (Oss) for kindly supplying large amounts of Folliculin Menformon and Dimenformon.

respectively with prolan from pregnancy urine and with gonadotropic hormone from the blood of a pregnant mare. Here, too, the pituitaries of rats react differently, according to their sex, but in a reverse way from my experiments. Enlargement of the anterior lobe in the female is caused by giving gonadotropic hormone, whereas in the male animal it is the follicular hormone that produces enlargement.

#### EXPERIMENTAL PITUITARY TUMOUR IN A FEMALE RAT

Only in one experiment have I observed a considerable reaction of the anterior lobe of the pituitary in a female animal (R 228).

Treatment commenced at an age of four weeks and at a weight of 35 g. The rat was given 5000 M.U. twice weekly, 280,000 M.U. of folliculin in all. In the 28th

TABLE II

*The Action of Œstrin on the Pituitary in Female Rabbits*

No.	Dose of hormone (M.U.).	Duration of treatment (weeks).	Total dose (M.U.).	Weight of pituitary (mg.).

K 266	12,500 twice weekly.	4	100,000	5.6
—	—	—	Average	16.92

week of treatment certain reactions pointing to cerebral disturbances were found in the animal. The rat turned and rolled only towards the right, ptosis of the right eye was present, the head was turned to the right, and the equilibrium of the animal was disturbed. It was therefore killed. On removal of the brain a very large tumour with a smooth surface was found in place of the pituitary (see Figure). It had a yellowish-green and in places dark red colour, and was the size and shape of a bean; the anterior and posterior lobe could not be identified as such. The optic nerves were invisible, being completely covered by the tumour, and the chiasma could only just be seen. The tumour weighed 250 mg., while the pituitary of the control animal was only 12 mg., an increase of over twenty times. On dissection the tumour was found to be very soft and crumbly; it was not possible to separate it completely from the nervi optici, because the tumour tissue had almost united with the nerves. I cannot yet make an exact statement regarding its histology, but I have sent it for examination to Prof. Erdheim of Vienna, who has an expert knowledge of the anatomy of the pituitary. I have myself examined a small piece of the tumour and I was impressed by multiple areas of hæmorrhage.

It is impossible to state why in this case the pituitary of a female animal reacted by forming a tumour, while the growth of female pituitaries generally remained uninfluenced by the oestrogenic hormones. The treatment however of the animal in which the tumour was found was continued ten weeks longer than in other female animals, and it is possible that the duration of the treatment is an essential factor.

#### REACTION OF THE PITUITARY IN RABBITS

After I had found that the pituitaries of rats vary in their reaction according to sex, I examined the reactions of other rodents to the application of

follicular hormone over a prolonged period. Immature female rabbits received 10,000–50,000 M.U. folliculin menformon or dimenformon, usually twice weekly.

Table II. shows an average weight for the pituitaries of the treated animals of 16.9 mg.; the same average weight was found in the control animals. After a longer treatment (12 weeks, K 268) the pituitary showed slight enlargement (24 mg.); pituitaries of similar weight, however, are also to be found occasionally in control animals. As we see, there is no marked influence on the size of the pituitary of the female rabbit after a prolonged treatment with follicular hormone. Whether or not this is also the case in the male animal is now being investigated.

#### SUMMARY

1. Administration of follicular hormone over a long period inhibits the anterior lobe of the pituitary so that the growth hormone and the gonadotropic hormone are not active. Dwarfed animals with hypoplastic genitals result.

2. The dysfunctioning pituitaries of such rats are enlarged and their weight may amount to four times the normal. This increase occurs in male rats only.

3. However, a very large tumour of the pituitary, produced in a female rat, was 20 times the normal size of the gland. This tumour produced signs of pressure on the brain and optic nerve.

4. The pituitaries of female rabbits do not enlarge after prolonged periods of folliculin administration. Whether or not this is the case in male animals is now being studied.

## Clinical and Laboratory Notes

### NINETEEN MONTHS' HUNGER-STRIKE

By H. BASIL ROSAIR, L.R.C.S. Irel., D.T.M.

MAJOR, I.M.D.; SUPERINTENDENT AND MEDICAL OFFICER, CENTRAL PRISON, BAREILLY, UNITED PROVINCES, INDIA

Convict Munshi Khan resorted to hunger-strike on May 18th, 1934. His weight was then approximately 130 lb.

Regular forcible feeding was begun on July 2nd, but before that date he had been forcibly fed on eight or ten occasions. On July 2nd his weight was 95 lb. and there were definite signs of weakness and exhaustion; from that time until Oct. 15th it ranged between 91 and 96 lb. By December it had dropped to 85—the lowest recorded during his nineteen months' hunger-strike. Between December, 1934, and January, 1936, his weight varied between 85 and 105 lb., the increase or decrease being mainly dependent on the quality and quantity of liquid food given.

Hunger pangs were confined to the first seven days of the fast. Nausea was an unpleasant symptom from time to time, but usually it was easy to check with a little bicarbonate of soda in barley water. The mind was always very active—if anything more alert than normal.

Forcible feeding through the nose by means of a soft rubber tube was the only form of feeding resorted to. I was fortunate in that the prisoner after the first ten days or so of forcible feeding offered little or no obstruc-

tion. The type of food material and the quantity used was varied as circumstances demanded—i.e., according to the man's condition. Frequently I reduced the routine feeds to one a day, and this would be allowed to go on for many days till the weight came down to about 90 lb. The nourishment given was selected from the following: milk, soup, raw eggs, mung dal, barley water, Glucose D-Roboleine, orange juice, cod-liver oil, and olive oil. Within six weeks of giving up his hunger-strike in January Munshi Khan had regained almost all his lost weight.

In feeding hunger-strikers it is important to avoid vitamin deficiency and to remember the value of fats and carbohydrates compared with proteins. Only carbohydrates and fats are stored as reserve fuel for use when food is insufficient or not available; proteins are utilised (mainly) for tissue repair, but muscle cells are not actually destroyed during starvation and fully recover when food is consumed.

With a well-nourished body, or when the correct type of food is used in forcible feeding, sufficient fat can always be provided for a prolonged fast. During my 15 years as medical officer of jails I have often had to order and conduct forcible feeding and I am convinced that there are no permanent ill-effects either upon mental activity or muscular strength. There are of course definite risks and danger when a prisoner refuses to be fed forcibly and offers obstruction with all the strength he can command; the possibility of exhaustion followed by collapse and even death must be borne in mind. Pneumonia owing to food entering the bronchial passage can ordinarily be prevented by not pouring any food into the funnel till the tube has passed well down.

So far as I am aware, no case of hunger-strike lasting as long as 19 months has previously been recorded.

### EXTRADURAL HÆMORRHAGE IN A CHILD OF 13 MONTHS

BY A. F. GOODE, M.B. Birm., F.R.C.S. Eng.

ASSISTANT IN THE SURGICAL UNIT, THE WELSH NATIONAL SCHOOL OF MEDICINE, ROYAL INFIRMARY, CARDIFF

I HAVE been able to find only one previous record<sup>1</sup> of middle meningeal hæmorrhage in a child so young as the case here described.

A girl, aged 13 months, was dropped from her father's arms, fell on her head from a height of about four feet, and at once commenced to scream, continuing to do so for about half an hour, after which she apparently went to sleep. However the mother noticed that the child did not close her eyes and thinking that she was having a fit, brought her to hospital. On admission to the Cardiff Royal Infirmary at 2 A.M. on June 21st, 1935, two hours after the accident, the child was unconscious, and soon after admission commenced to have attacks of twitching involving the left side of the face and the left arm, and later the left leg.

*Physical signs.*—When first seen by me at 5 A.M. the child was still unconscious with a right temporal hæmatoma and the left arm and leg showing flaccid paralysis. There was conjugate deviation of the eyes to the right, the pupils themselves being equal but small and reacting to light. The pulse-rate which had been 80 on admission was now 158. In view of the temporal hæmatoma and the twitching of the left side of the body followed by paralysis, a diagnosis of right middle meningeal hæmorrhage was made.

*Operation.*—Immediate operation was carried out under local anæsthesia. A temporal skin flap was turned down. Through a fissured fracture running across the squamous

temporal blood was oozing. A trephine hole was made in the skull about 1 in. above the zygoma, a considerable quantity of jelly-like clot removed and the meningeal vessels exposed. Bleeding was now profuse, from beneath the bone, and the trephine hole was enlarged upwards and it was found that both the middle meningeal artery and vein (anterior division) were torn. Both artery and vein were under-run with a catgut suture. It was necessary to tie both ends of the vessels to stop the bleeding. The wound was closed with a small drainage-tube.

The child recovered consciousness about four hours afterwards and had a very stormy convalescence for a few days, the temperature never falling below 102° F. and reaching 104° on several occasions. After the fifth day the temperature remained within normal limits. For three days there was a tendency for the eyes to deviate to the right. The left-sided paralysis steadily decreased but it was nearly three weeks before it had disappeared completely. When seen in January of this year the child was perfectly well.

The age and absence of concussion were misleading features in this child's history; but the fits and paralysis, together with the temporal hæmatoma, made the diagnosis more obvious. In fact extradural hæmorrhage, more often than not, appears to give atypical symptoms.

The necessity for tying both ends of the vessels in this case gives support to Wood Jones's theory of the origin of the bleeding, which he considers comes from the vein. Although consciousness was fairly rapidly regained, the paralysis persisted for a surprisingly long time after craniotomy and ligation of the vessels.

### PANTOCAIN L

#### A REPORT ON 160 CASES

BY AHMED ABDEL NABI, D.M. Cairo

CAPTAIN, EGYPTIAN ARMY; SURGEON, EGYPTIAN ARMY GENERAL HOSPITAL, CAIRO

FOR the last thirty years spinal anæsthesia has been used in Egypt on a very large scale. The drug mostly employed was Stovaine, on which the single-handed surgeon in the country relied for the greater part of his work on the abdomen and the lower extremities. Its use in hospitals has taken a big burden of anxiety and worry from the shoulders of the surgeon. The drawback of stovaine was the fall in the blood pressure, which often caused shock. Again, the rapid disappearance of the anæsthesia made it necessary to administer a general anæsthetic in the last stages of major operations.

Having given stovaine in 1500 cases during the last few years, and having gained much experience of its use, I sought some other drug that would not cause a big fall in the blood pressure. Pantocain L\* was chosen for trial, and I started my series of 160 cases in November, 1934. As usual when trying new drugs I was very careful and cautious in selecting my first few patients, but the results were so encouraging that I now believe that pantocain is the spinal anæsthetic that should be used everywhere.

Pantocain (*p*-butyl-aminobenzoyl-dimethyl-amino-ethanol hydrochloride) is a novocain derivative. It is a white crystalline odourless powder, which is readily soluble in water and normal saline. It is not affected by boiling and it keeps stable indefinitely. It is supplied in ampoules, each containing 3.75 c.cm. of an 0.8 per cent. solution of the drug (i.e., half a grain in each ampoule). The specific gravity of the

<sup>1</sup> Wakeley, C. P. G., and Lyle, T. K.: Problem of Extradural Hæmorrhage. A Report of 14 Cases. *Ann. of Surg.*, 1934, c., 39.

\* Made by Bayer Products Ltd.

solution is lower than that of the cerebro-spinal fluid, a fact which should be always borne in mind.

My series of cases consisted of 123 males and 37 females, ranging from between 15 and 55 years of age. The drug is contra-indicated in cases of arterio-sclerosis, severe sepsis, severe anæmia, old age, and nervous disorders.

#### TECHNIQUE

The instruments and drugs required are: (1) morphia (0.01-0.02 g.) and atropine (0.001 g.) ampoules; (2) pantocain L in ampoules (3.75 c.cm.); (3) Pantocain Racedrin\* (2 c.cm. containing grs. 2 of racedrin); (4) one 2 c.cm. record syringe; (5) one 10 c.cm. record syringe; and (6) a long thin-bored needle for the spinal puncture.

*Preparation of the patient.*—A mild aperient is given one day before the operation. *Strong purgation is not required.* An enema is usually administered in the early morning, but this could be omitted in weak patients. Twenty to thirty minutes before the operation an injection of morphia and atropine is given and the patient is kept in a quiet place.

*Position and doses.*—The specific gravity of the pantocain solution being lower than that of the cerebro-spinal fluid, the drug should on no account be administered while the patient is sitting up. He should always be lying on the side opposite to that on which the operation is to be performed, but if there is to be a double operation—for example, a double inguinal hernia—or if the incision is in the median line he lies on his left side. He must be put in the Trendelenburg position, the degree of tilting the table varying according to the site of the operation: the head should always be kept lower than the buttocks. Before injecting the pantocain, an average of 1.5 c.cm. of pantocain racedrin is injected along the proposed line of the lumbar puncture, to act as a local anæsthetic and to raise the blood pressure. If the blood pressure is high, only 0.5 c.cm. is to be injected.

The accompanying Table shows the dose and site of injection, and the inclination of the table, according to the operation:—

	Dose in c.cm.	Site of injection.	Speed of injection in secs. per c.cm.	Inclination.
Lower extremities ..	2	L. III.-IV.	5	10°
Perineum ..	1	L. IV.-V.	5	10°
Lower abdomen ..	2-2½	L. IV.-V.	4	5°
Middle abdomen (to umbilicus) ..	3	L. III.-IV.	4	5°
Upper abdomen ..	3½	L. II.-III.	3	5°

When the racedrin solution has been injected into the space chosen, the long narrow-bore needle is pushed into the spinal canal in the usual manner. The stillette is taken out and the 10 c.cm. syringe containing the pantocain solution is jointed to the needle, and an equal amount of cerebro-spinal fluid is drawn and the mixture is then slowly injected. The patient is now turned on his back and the table is tilted more (5-10 degrees) into the Trendelenburg position, according to the site of the operation.

*After-treatment.*—The foot of the bed is raised on blocks for a period of 8-12 hours. The patient may be given fluids very early after the operation.

#### EFFECTS

*Onset and duration of anæsthesia.*—Anæsthesia generally sets in after 1-2 mins., but in some cases the onset is delayed up to 8 mins. The duration of

anæsthesia is 2-4 hours and the patient is generally unable to move his lower limbs before 5-8 hours.

*The blood pressure.*—I am accustomed to record the pulse and blood pressure: (1) before morphia; (2) after morphia; (3) 10 and 20 minutes after pantocain injection; and (4) at end of operation. The blood pressure taken before the operation gave me an idea of the amount of racedrin to be injected. The normal blood pressure is better checked a day or two before the operation. Patients sometimes get very nervous immediately before; this causes a false reading to be recorded and, consequently, a wrong dose of racedrin to be given; both systolic and diastolic readings are affected in this way. One of the three patients in whom I noticed a fall in blood pressure was a little worried and complained of dragging pains in the abdomen. I gave 5 c.cm. of coramine intravenously and he again became cheerful and happy.

On the average there was a rise of 20 mm. in the systolic pressure, which appeared ten minutes after injection and lasted over half an hour; in only three cases did I notice a fall and it was slight. The pulse-rate was increased.

#### TWO ILLUSTRATIVE CASES

The following is a record of blood pressure given in two illustrative cases:—

CASE A.—Aged 26. Acute appendicitis.

CASE B.—Aged 40. Complete uterine prolapse and lacerated cervix.

—	Blood pressure mm. Hg.				Pulse-rate.	
	Systolic.		Diastolic.		A.	B.
	A.	B.	A.	B.		
Before morphia ..	115	135	70	86	100	72
After ,, ..	115	135	75	84	98	72
10 minutes after pantocain ..	140	155	90	100	110	78
20 minutes after pantocain ..	140	150	90	96	108	78
At end of operation	130	140	85	90	96	75
Racedrin, c.cm. ..	A. 1.5		B. 1.25			
Pantocain, c.cm.	3		1.5			
Space injected ..	Lumbar 3-4		Lumbar 4-5			

#### CONCLUSIONS

(1) The drug is safe and the anæsthetic effect lasts long. (2) Little or no headache follows its administration. (3) Retention of urine is rare (2 per cent.). (4) No cases of paralysis have been observed. (5) There is little or no fear of a fall in the blood pressure, as compared with other spinal anæsthetics.

I should like to offer my sincere thanks to Major FitzGerald Powell Bey, principal medical officer, Egyptian Army, and Major R. J. Rosie Bey, senior medical officer, Egyptian Army General Hospital, for their encouragement and for allowing me to use this drug in the Egyptian Army General Hospital.

BRISTOL CHILDREN'S HOSPITAL.—A new out-patient department, which will cost about £24,000, is urgently needed at this hospital. During the last four years the hospital has been rebuilt at a cost of £40,000, and a nurses' home erected. A great many children assist the institution, thirty-two schools contributing £25 a year each to support a cot.

## MEDICAL SOCIETIES

### MEDICO-LEGAL SOCIETY

AT a meeting of this society held at Manson House under the chairmanship of Sir WILLIAM WILLCOX on March 26th, an address was given by Dr. L. A. WEATHERLY on

#### Debatable Medico-Legal Episodes

in his long life of practice as a mental expert. It was in 1886, he said, that he became an alienist. His father was a country doctor with 13 children, eight of them boys, who owed their good education to the fact that their father had a wealthy resident patient, an eccentric man of genius, a schoolfellow of Thackeray and a friend of Gladstone. This was the background of his youth and in his student days at Bristol he spent his spare time at the county asylum, Fishponds, with George Thompson. In 1877 when he married, his wife consented to have a resident patient. He joined the Medico-Psychological Association and there got to know John Bucknill, Haek Tuke, George Savage, David Barr, Urquhart, Yellowlees, Clouston, Mercier, and—an association that meant more to him than any other—Henry Maudsley. In 1886 he bought a private mental hospital at Bath and a few years later was appointed deputy coroner for Somerset. The first inquest he held was on an imbecile child who had been hounded to death by drowning in the village pond. On arriving he found the jury had already viewed the body and were assembled in the inn around a table on which was a punch bowl and a pipe and tobacco was provided for each juror. He left the place a very unpopular man. At Bath he became friendly with the police surgeon, who was horrified at the number of boys sent to prison for trivial offences. Permission was obtained for Dr. Weatherly to see some of these juvenile offenders, and he liked to think he was instrumental in getting different treatment for many of them. In 1908 he was called to give evidence before the Royal Commission on the Weak-minded. He had a firm belief in the value of the coroner's court, and hoped its privileges would not be taken away.

His first important medico-legal case was a charge of murder heard at the Taunton Assizes in 1886 before Mr. Justice Field. Mr. Thomas Bucknill and Mr. Charles Matthews appeared for the defence. The accused was the son of a well-known medical officer of health. He was born at an asylum while his mother was suffering from the melancholic stage of manic-depressive insanity. Soon after birth he was seen to be abnormal; at school he developed epilepsy. His mother was keenly attached to him, but his two sisters shunned him, and after one of them had deprived him of something he was in the habit of having he became very angry; he was found walking in the streets of the town and his sisters when they passed him cut him dead. He felt he could brook their cruelty no longer, went home and wrote a letter containing these words:

"Dear father and mother, I leave everything that belongs to me to my dear mother. I have been treated so badly by my sister C—that I feel I must put an end to her life by shooting; and, knowing that I shall have to die for it, I shoot myself. Good bye to all; hoping you will have a happy time. Good bye, dear father and mother."

With that letter, and with a judge determined to interpret the McNaghten rule in its narrowest

sense, the poor alienists had a rough time. The judge would not allow Dr. Weatherly to give his opinion on the condition of the boy's mind, and witnesses were tied down to answering the question "Can you say that this boy did not know the difference between right and wrong in the face of that letter?" Dr. Needham, later superintendent of Barnwood House, had been subpoenaed to give rebutting evidence; he had to tell the prosecution that his evidence would be favourable to the defence and was not called. The verdict was "Guilty but insane," and the boy was sent to Broadmoor. Some years later he hanged himself at the prison. The alienist giving evidence on insanity was sometimes placed, Dr. Weatherly said, in a difficult position; he could not declare that he had microscopically examined the cells in the brain of the accused, and that certain cells believed to be concerned with intellect were seriously affected; nor could the will power or the emotions be weighed in a scale and assessed. Moreover, the affective portion of the mind was often responsible for a crime without the intellect acting at all. The judges who adhered to the McNaghten rule took no account of that affective region of the mind. His own belief was that grades of murder should be recognised.

Kleptomania, Dr. Weatherly contended, was a true disease of the mind. He had had to give evidence in many cases, and his experience told him that if the tendency was not dealt with early it would develop into systematic thieving on a larger scale. A case of this kind, tried by Mr. Justice Denman, was that of a post office employee in Bristol who had been taking to his lodging registered letters and other postal packages, also boxes of knuckle bones, and silks and satins. It was ascertained that he had been a butcher's boy, and had later been employed in a haberdasher's shop. Dr. Weatherly spent three hours in the witness-box and showed that the man had many of the stigmata of imbecility. The verdict was "Guilty but insane" and the patient was allowed to remain at Fishponds. Dr. Weatherly next dealt with sexual offences, commenting on the extraordinary position of the law which allowed magistrates to decide on some offences while others had to be sent to the assizes. He related the case of a public official charged with indecent exposure; the man's sexual life had completely altered after an operation for appendicitis. After six months under medical care he was able to go back to his family. Dr. Weatherly then referred to Section 49 of the Lunacy Act, relating a case in which the asylum superintendent and his staff refused to allow a patient to be visited or his papers to be inspected. The law, he submitted, required amendment; the matter was discussed by the Medico-Legal Society some years ago.

In conclusion, Dr. Weatherly said he had watched with great interest the growth of the Medico-Legal Society, but he thought its practical usefulness should be extended. For instance, Mr. Claud Mullins had made out a strong case for some alteration of the law in sexual offences. He wanted the society to set up a parliamentary bills committee.

Mr. Justice HUMPHREYS said he did not think there was any likelihood that coroners' courts would be abolished. Somebody must deal with the man found with a broken neck, who might have had it broken by somebody, or might have fallen out of a window, or might have committed suicide. A good

thing was done when Parliament decreed that as soon as a person was in custody for causing the death of somebody, the coroner's inquiry must cease. He had found coroners doing their very difficult work not only fairly but with great tact. He refused to be drawn into a discussion of the McNaghten rules; he was tired of them, and, he added, they were getting rather old.

Sir LAWRENCE BROCK (chairman of the Board of Control) said that Government departments were often blamed because legislation did not keep pace with the hopes of enthusiasts; people should remember that no Government could legislate far, if at all, in advance of public opinion. Hence the value of societies of this kind which could help to bring conflicting views to a focus and to educate public opinion. He hoped the desire for the humaner treatment of mental disorder which Dr. Weatherly had manifested in his long life would continue to animate the members of the society.

The CHAIRMAN, in thanking Dr. Weatherly for his address, said it was to him that the Medico-Legal Society owed its inception.

## ROYAL SOCIETY OF MEDICINE

### SECTION OF RADIOLOGY

At a meeting of this section held on March 20th the chair was taken by Dr. C. G. TEALL, the president, and Dr. E. W. TWINING opened a discussion on the value of

#### Radiology in Neuro-Surgery

The neurologist and neuro-surgeon, he said, had been fortunate at finding, just when they needed it, a development of radio-technique adequate for their purpose. The common intracranial tumours were gliomas (40-50 per cent.) angiomas, tuberculomas, meningiomas, pituitary tumours, acoustic neuromas, and cysts. Gliomas came low in the group producing direct radiological signs. There might be local bulging of the skull, a visible vessel over the tumour, or hydrocephalus. They sometimes calcified, showing a single dot, multiple dots, convoluted or radiating trabeculae, or a circular shadow. Meningiomas were not invasive but pushed the brain out of the way and often produced direct radiological signs. Some of the evidence was extremely difficult to assess. Calcification was rather uncommon in these tumours, and could not be distinguished from that associated with glioma. Pituitary tumours (20 per cent. of the total) appeared in the first half of life and the patient might go blind suddenly if the diagnosis were not made early. The sella was ballooned, often V-shaped; the anterior clinoids remained unaffected usually, but sometimes were tapered or pulled upwards. The condition had to be distinguished from the altered sella due to intracranial pressure. An arachnoid cyst might give signs indistinguishable from those of a pituitary tumour. Acoustic neuroma (9 per cent.) showed often an erosion or dilatation of the internal meatus, which was best demonstrated by Towne's method. Erosion of the petrous might be due to cholesteatoma resulting from middle-ear disease. Suprasellar tumours (5 per cent.) most often grew up from Rathke's pouch in young people who showed hypopituitarism and polyuria. X rays might show calcification but gross alteration of the sella was rare. Ventriculography was helpful in

the diagnosis of these tumours. Hydrocephalus yielded direct signs: rounded and thinned skull, widened sutures, and deepened digitate impressions in children, but often only sellar erosion in adults. Ventriculography was useful here also. The problem was to find where the block was. A head-tilting method would often fill the posterior part of the ventricular system; if the ventricle did not fill with this method there was nearly always a lesion. The infundibular recess seemed to press on the sella and cause osteoporosis of the bone, often quite flattening the pituitary. The third ventricle might be deformed by such lesions as suprasellar meningioma, optic nerve glioma, aneurysm of the anterior cerebral artery, pituitary tumours, craniopharyngeal cyst, and glioma of the optic chiasma. The use of Thorotrast had certain advantages in the radiology of cranial lesions.

#### THE MENINGIOMAS

Mr. HUGH CAIRNS said that meningiomas were for the most part benign and attached to the dura. They might be found in the vault or base. Typically they were composed of spindle cells with a tendency to whorl formation in which at times calcium—or even bone—was deposited. Sometimes they were part of a general neoplasia. Some of them gave no X ray signs. A few showed only signs of raised intracranial pressure, but more often bone formation or bone invasion was visible. The reaction to invasion was usually excessive deposition of bone, but might be excessive absorption. Meningiomas on the base of the skull produced such symptoms as proptosis. Areas of increased thickening might be seen without palpable lump. An important sign was a small endostosis on the inner surface, indenting the meningioma. These endostoses were not always associated with thickening of the bone; traction seemed to be one of the factors in their production. Some of them showed as areas of diminished density. Tangential views were essential if any area showed unusual vascularity, with vessels converging towards a point. The vascular changes in meningioma included increase in number and size; appearance of numerous fine channels, usually inside, sometimes in the substance and occasionally on the outer table; and increase in size and number of the diploic channels. Radiograms of abnormal vessels warned the surgeon when to anticipate excessive blood loss at operation. Some meningiomas obtained a lot of their blood-supply from the cerebral vessels and in this case the bone changes were much less intense. The olfactory groove tumours were the most difficult to diagnose; they showed a dark line along the groove, but this might appear in normal skulls and was not diagnostic unless the patient had also lost his sense of smell. Osteoma showed much sharper outlines than meningiomas. Leontiasis ossea gave rise to dense areas in the skull. Head injuries in childhood and syphilitic osteitis of the skull might show radiographic appearances resembling meningioma. Metastatic carcinoma could not be distinguished radiographically, and chronic alcoholic meningitis might closely resemble meningeal tumour. Positive radiological evidence had been available in 70 per cent. of his cases.

#### THE LATERAL VENTRICLES

Dr. M. H. JUPE said that calcified tumours within the lateral ventricle were uncommon. The more deeply the tumour lay the more difficult was both diagnosis and operation. Calcification was therefore an inadequate guide in any case. Ventriculography

gave the information required. Perforation of the septum lucidum might be revealed by "waviness" without bulging. Congenital absence of the septum was easily recognised. Tumour of the corpus callosum had to be distinguished from congenital absence; it did not show the convexity of the latter condition. If the foramen of Monro were blocked a single injection would not fill both ventricles; it was important to know on which side the bulk of the tumour lay. When the tumour arose more posteriorly the ventricles were more separated, and an antero-posterior view in a modified Towne position was useful. A large tumour at the base would deform the lateral ventricle. Failure to fill the descending horn pointed to temporal lobe involvement. Pure basal ganglia tumours and cysts of the third ventricle gave little indication of their origin, but could be distinguished from each other by air injection. As the former were treated by decompression and radiation and the latter could be removed, diagnosis was important. Sometimes stereoscopic views would reveal tumours not seen in direct views.

#### THE OPTIC CANALS

Mr. G. JEFFERSON pointed out that the examination of these canals had many applications and was quite simple. The cerebro-spinal fluid space was carried forward along the optic nerve and the prolongation might be dilated in hydrocephalus. An intrinsic tumour of the nerve itself produced the maximum disturbances. It was most important to examine the canals in cases of suspected chiasma tumour which might extend forwards into the nerve. To secure good views the head must be carefully positioned by a standardised technique. The normal canals attained a size of about 5 mm. at the age of 3 and thereafter did not alter. Erosions of the bony bridge between the optic canal and the sphenoidal fissure were caused by aneurysm and were visible on radiography. Meningioma from the anterior wing of the sphenoid caused disappearance of all the structures—and not the suppression of the bridge with a fairly normal optic canal. Meningiomata of the olfactory groove caused monocular blindness by pressure on the nerve and not by affecting the canal.

#### CEREBRAL BLOOD-VESSELS

Mr. D. W. NORTHFIELD said that visualisation of the vessels could give valuable information if they were properly filled and the normal patterns were known. The external carotid circulation was slower than the internal carotid and therefore the superficial vessels were not seen. According to the number of seconds of delay between the injection of thorotrast and the exposure, the arterial, sinus, or cortical venous systems were visualised. Abnormal collections of thorotrast indicated aneurysm or congestion. Vascular meningiomas showed typical smudge-like opacities. Vascular gliomas showed many large parallel vessels of all calibres. A tumour could be localised by displacement of vessels. Pituitary tumours might affect the carotid sinus, straightening out the carotid syphon curve. Tumours of the temporal lobe were often difficult to diagnose, but were shown clearly by displacement of the Sylvian vessels upwards.

#### TUBERCULOMATA

Dr. J. PURDON MARTIN showed slides illustrating tuberculomata shadows. In the acute stage they did not show on the film but later they calcified and then the patient often began to suffer from fits.

In one of the few cases that had been verified by operation the shadow was near the surface and lobulated. The outline was always irregular and sharply defined and the calcification dense. The aneurysm shadow was much more regular in outline.

The PRESIDENT said that, while much of the work was highly specialised, certain signs were clear for all who had eyes to see, and radiologists must learn to make early diagnosis if the full value of radiology in neuro-surgery was to be obtained.

### NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

To the account of a meeting of this society given in our last issue may be added the following note on

#### Repeated Ectopic Pregnancy

Dr. J. W. BRIDE, under the title of Recurring Ectopic Pregnancy, reported the case of a woman who had (1) a normal pregnancy by her first husband; (2) a left ectopic pregnancy by her second husband, 13 years later, which was treated by salpingo-öophorectomy; (3) a normal pregnancy 2½ years after the ectopic pregnancy; and (4) an ectopic pregnancy nine months after the second normal pregnancy. At the operation for the first ectopic pregnancy the right appendages were regarded as normal—a finding which seemed to be confirmed by the subsequent normal pregnancy. There was no disease of the appendix, no history suggestive of gonorrhœal infection and no sign of such infection at the second operation. The puerperia in each pregnancy had been uneventful.

Prof. MILES PHILLIPS thought it better to reserve the term "recurrent" or "recurring" for cases of tubal pregnancy in a tube which had been repaired at a previous operation after incision into its wall to remove a tubal mole. The term "repeated" was in general use for cases of pregnancy in the opposite tube after a previous operation (generally excision) for a tubal pregnancy. He referred to a case of recurrent tubal pregnancy in a conserved tube, after an interval of 16 months, which necessitated salpingectomy. He also recalled F. W. Ramsay's well-known case of successful uterine pregnancy after two operations for tubal pregnancy, in the first of which a tube had been removed and in the second conserved. On the other hand, Aleck Bourne had recorded fatal rupture of pregnancy in a conserved tube.

Mr. C. H. WALSH said he had records of 80 ectopic pregnancies, 43 of which were on the right side and 37 on the left. Half were tubal abortions and half tubal ruptures. Slightly over half were in multiparæ; slightly over half were presumed to be due to congenital defects of the tube, and slightly less than half to old infection. Of the 80, 5 were recurrent, 4 in the opposite tube, and 1 in the stump of a partial salpingectomy. There were no immediate deaths in the series, but 1 death three years later from intestinal obstruction.

Dr. BRIDE, in reply, agreed with Prof. Phillips about terminology. The second ectopic pregnancy had been treated conservatively by tubal resection, and he hoped that if the patient's wishes were fulfilled, and she became pregnant, the result would not be a cornual pregnancy.

## REVIEWS AND NOTICES OF BOOKS

**Insulin**

*Its Production, Purification, and Physiological Action.* By DOUGLAS W. HILL, B.Sc. Brist., Ph.D. Liverp., Lecturer in Chemistry, University College, Exeter; Special Lecturer in Organic Chemistry, University of Bristol; and FREDERICK O. HOWITT, M.Sc., Ph.D. Lond., F.I.C. With a foreword by Prof. E. C. DODDS. London: Hutchinson's Scientific and Technical Publications. 1936. Pp. 219. 12s. 6d.

THOUGH a large number of books have been written on insulin, few have been concerned with its more chemical aspects. These take up a large part, approximately one-half, of this monograph, which aims at giving a complete summary of the literature on insulin except that dealing with its clinical applications. Anyone who has attempted to keep abreast with this subject will be grateful to the authors for the most exhaustive presentation of the work done on its chemistry and preparation that has yet appeared. It is designed for specialised workers and therefore includes, at the end of each chapter, references to all the original sources made use of. The number of publications dealt with is exceptionally large for a book of this size; the name-index alone occupies some 24 columns. This constitutes such a valuable feature that it is perhaps ungrateful to suggest that the inclusion of a list not only of original communications to scientific journals, but of the more important reviews and monographs by established authorities would have been a useful addition.

After a brief introductory survey of diabetes mellitus the chemical and preparative section opens with a summary of the pioneer work on the isolation of the hormone, culminating in the discoveries of the Toronto workers in 1921 and the following years. The chapter on the methods of preparation employed by various workers and the yields of active principle obtained is excellent. The distribution of insulin in different tissues is also reviewed here. There follows a description of the methods used for purification of the crude material, and a valuable account of the chemical and physical properties is given. This includes a consideration of crystalline insulin and of the chemical nature of the highly purified substance. Considered in relation to this chemical work the final chapter on possible substitutes for insulin makes interesting reading, though it is clear that no satisfactory substitute for the natural hormone is available as yet. The substances hitherto discovered, whether synthetic or natural, throw little light on the pharmacological mechanism of insulin action, but in so far as they may in the future lead to the preparation of effective substitutes, the definition of their properties is timely.

Of the remainder of the book some 40 pages are devoted to the physiological properties of the hormone, including sections on hypoglycaemia, changes in composition of body fluids following insulin administration, and the relation of insulin to other internal secretions. The authors then review the mode of action of the pancreatic hormone and proceed to consider the regulation of insulin secretion, the physiological control of blood-sugar level, the relation between the internal and external secretions of the pancreas, and finally the present state of knowledge of the effects of insulin upon carbohydrate metabolism. The wide differences of opinion on this subject to

which conflicting experimental results have given rise, make it difficult to present a fair picture. On the whole this has been achieved, though occasionally it may seem that due weight is not given to certain important observations, probably from a desire to give space to all relevant ones. The concluding chapter on the biological assay of insulin preparations will be of practical value to those whose duty includes such determinations. The typography of the book is unusual in a scientific production and will not appeal to those who dislike prominent headlines. But there is something to be said for the view that highly technical matter is difficult to read and that help in differentiating the sections and sub-sections should not be despised.

**Surgical Diseases and Injuries of the Genito-urinary Organs**

Second edition. By Sir JOHN THOMSON-WALKER, M.B., C.M. Edin., F.R.C.S. Eng., Consulting Urologist and Emeritus Lecturer on Urology, King's College Hospital; Consulting Surgeon, St. Peter's Hospital. Edited by KENNETH WALKER, M.B., B.C. Camb., F.R.C.S. Eng., Lecturer on Venereal Disease, St. Bartholomew's Hospital; Surgeon with charge of Genito-urinary Department, Royal Northern Hospital. London: Cassell and Co., Ltd. 1936. Pp. 974. 32s. 6d.

THE first edition of this book appeared in 1914. It quickly established itself in this country as a standard work, and sold so widely abroad that soon the edition was exhausted and the book became unobtainable. Unfortunately the war and the obligations of his practice prevented the author from giving up the time necessary to bring out a second edition. During the last 20 years urology has advanced rapidly as a branch of surgery, and in order to bring the book up to date it has been necessary to rewrite most of it.

The new edition retains the original aim of reflecting current opinions of the day and at the same time bearing the impression of the experience and individual views of the author. In order to lighten the author's task Mr. Kenneth Walker has undertaken the work of editor, but Sir John Thomson-Walker has coöperated actively in the work of revision and has himself contributed many of the new chapters. The editor's main embarrassment must have been the wealth of new material at his disposal. Additional chapters on renal function tests, transurethral operations, obstruction at the bladder neck, impotence and sterility have been included. Amplifications elsewhere have been made necessary by the increasing importance of X rays in urology, not only in the realms of diagnosis but also of treatment. When the first edition was being prepared pyelography was in its infancy. It has since gained for itself a prominent position among aids to diagnosis, and training in interpretation of pyelograms has become an indispensable part of the urologist's equipment; plates illustrating the typical pyelographic appearance of different lesions of the kidney are interspersed throughout this book. All the plates (25 in colour and 33 in black and white) are of high quality, and nearly 300 illustrations are incorporated in the text. Most of the coloured plates are reproduced from paintings made by Mr. Thornton Shields in the operating theatre of appearances seen through the

cystoscope. They are sufficiently realistic to help those who are not expert cystoscopists to recognise the lesions portrayed.

The labour involved in bringing this work up to date has been well spent, and it will be welcomed at home and abroad as a sane presentation of current British teaching.

### Die Störungen des Lichtreflexes der Pupille

*bei denluetischen Erkrankungen des Zentralnervensystems. Beiträge zur Frühdiagnostik der Lues nervosa.* By Dr. OTTO LÖWENSTEIN, formerly Professor at the University of Bonn, at present at Nyon, Switzerland (Klinik la Métairie). Basle: Benno Schwabe and Co. 1935. Pp. 92. RM.4 (5 Swiss francs).

Dr. Otto Löwenstein has long made a special study of the reaction of the pupil to light, both in health and disease. For his purposes the ordinary clinical test is wholly inadequate and even the pupilloscopes devised by Hess and Sommer are insufficient. The first to use cinematography in this connexion was Weiler, but his method entirely fails to measure the consensual reaction of the unilluminated eye. By his improved method Löwenstein claims to have invented a kinemotographic apparatus by means of which all the phases of the direct reaction to light of the pupil and also of the consensual reaction can be studied. The initial difficulty of photographing a pupil in the phase of dilatation is got over by means of filtering the light through blue-violet reflectors, and the complete apparatus includes a device by which the various phases and their extent can be represented by a tracing on paper. A number of diagrams of curves so taken are reproduced and by means of them the following points are elucidated. There are four typical varieties of the normal pupillary reaction to light. After a short latent period which varies between 0.06 and 0.25 of a second there may be either (1) rapid contraction and rapid dilatation, (2) rapid contraction and slow dilatation, (3) slow contraction and rapid dilatation, or (4) slow contraction and slow dilatation. Fatigue caused by repetition of the flash occurs only after repeated flashes in the normal, but much sooner in a patient with disease of the central nervous system. In all normal cases the reaction of the right and left eyes is similar, and the phases of the consensual reaction follow very closely after the direct. The psychic dilatation of the pupil is, of course, very liable to complicate the reaction to light and hence the necessity of making the tests of the direct and consensual reactions simultaneous. Any considerable deviation from the normal points to an abnormal state of the central nervous system, and as by far the most frequent cause of this in cases in which the diagnosis is obscure is syphilis, these pupillary abnormalities may sometimes afford invaluable help. Dr. Löwenstein's study of these pupillary symptoms in relation to syphilis is based on an investigation of more than 100 cases during the last ten years. Many of them came under his notice at a period of the disease when the Wassermann reaction was negative and the diagnosis was doubtful. In others the clinical symptoms left no doubt; most were in an intermediate stage when syphilis was suspected but not proved. He concludes that the obscure pupillary symptoms, amounting to much less than anything capable of ordinary clinical demonstration, such as

the Argyll Robertson pupil, may if detected point to the diagnosis at a time early enough to give therapeutic measures an excellent chance.

Among the particular abnormalities that are discussed are: symptoms of fatigue occurring unduly early after repeated tests of the light reflex; definite differences between the response of the right and the left pupils to the light stimulus; marked differences between the direct and the consensual response; and differences in the latent period of the two pupils. Dr. Löwenstein has been able to study in cases of early tabes the stages of which the final one is the Argyll Robertson pupil, and also the curious phenomena which precede the so-called paradoxical pupil reaction.

Since there are so many varieties in the details of the pupillary reaction to light in normal individuals it is not claimed that these researches can ever provide an easy substitute for a complete clinical and pathological diagnosis of obscure cases either of early or latent syphilis, or of other diseases such as schizophrenia, but the method appears to afford an additional tool which is likely to be of increasing importance. Any neurologist who finds himself in Switzerland in the near future should take the opportunity of becoming acquainted with it.

### History of St. Thomas's Hospital

By F. G. PARSONS, D.Sc., F.R.C.S., F.S.A.  
Vol. III. London: Methuen and Co., Ltd. 1936.  
Pp. 274. 10s. 6d.

THIS volume sets out the story of St. Thomas's Hospital in the nineteenth century and is preceded by a brief review of the activities and personnel of the institution during the previous hundred years. A description of the hospital, given in the opening pages, enables one to see that the bond of union between St. Thomas's Hospital, the senior of the two institutions which until some 80 years ago stood facing each other in Southwark, and Guy's Hospital, its neighbour, was a loose one and attended with many circumstances which made the separation of their activities wise and probable. The chapter dealing with the last 25 years of the "United Hospitals," as they were then termed, makes very amusing reading and one can gather that Wakley, the founder of THE LANCET, who was a medical student at the joint schools, had a firm foundation for many statements which in the early days of THE LANCET compelled him to defend various libel actions. The next section of the book, taking the hospital up to 1845, deals with a period of distinct depression in the medical school. Students became fewer and though eminent men had places on the staff they do not seem to have discharged their duties with much altruism. In 1857 St. Thomas's Hospital moved from the Borough to take up a temporary home in the Surrey Gardens, until in 1863, after negotiation with the Metropolitan Board of Works, a site was acquired upon the new Albert Embankment. The years which intervened between the removal of the hospital from its old home and the acquisition of its new palace must have been very trying ones for the authorities. What seems to have been the central building was a large and abandoned music hall "capable of being divided into three floors in such a way as to hold two hundred beds, as well as an out-patient department and dispensary." Mr. Parsons's description continues: "Other buildings there were, ranging from mere dens and cages to

the stately giraffe house which was used as a cholera ward, but for all some use was found. A pavilion made a chemical laboratory, and I have heard Dr. Stone say that the elephant house became the dissecting room. The other departments of the medical school were housed in a large iron shed which was specially built for the purpose. There was, I am happy to say, no attempt to lodge the resident staff in cages and aviaries since houses in the neighbourhood were rented for them; not could a place where the governors might meet be found; and so, after the last court meeting in the old hall on July 16th, 1862, the governors met for nine years in the Terminus Hotel at London Bridge Station, an hotel which was built upon property belonging to the hospital." Now comes an extraordinary fact. The way in which the hospital was conducted in these circumstances must have been highly creditable to the much tried authorities, for at this time it was selected by Florence Nightingale as the site of her training school for nurses.

The remainder of the work dealing with the close of the nineteenth century is without the piquancy of the earlier story, for we are now in an environment to a great extent familiar to all who know what is implied by hospital life. It contains interesting and accurate notes on the personalities of the medical and administrative staffs during the later phases dealt with in the history, and the names recorded should make every student of St. Thomas's Hospital proud of his school.

### The Treatment of Asthma

By F. T. HARRINGTON, M.R.C.S., L.R.C.P.  
London: H. K. Lewis and Co., Ltd. 1936.  
Pp. 112. 6s.

THIS little book gives a full exposition of the general hygienic treatment of asthma. If the author had been content to stick to practical details and eschew theorising, it would have been admirable, for the advice is for the most part sound. As it is, there is much that will irritate the scientific mind. Asthma is attributed to toxæmia plus irritation, and the toxæmia is held to be the result of improper feeding. The nature of the toxin is not revealed, and it is hard to see what part food intoxication plays in hay-asthma or in occupational asthmas such as those of cotton operatives and similar workers. We know very little about the digestibility of foods, nor can we satisfactorily explain why attacks of asthma are induced by large meals and relieved by fasting. Empirically it has been found that certain food combinations are better tolerated by asthmatics than others. It is possible that these phenomena are due to mechanical or reflex disturbances comparable with the carotid sinus mechanism, and until we know more about their production it is unwise to dogmatise. When Dr. Harrington says, "It is of interest to note that when milk and meat are both included in the diet, histamine is produced and can be found in the sputum—histamine being a broncho-constrictor," he is hinting at a process which is almost inconceivable. In the practical part of the book the diet, the care of the digestive tract, the skin and the nose, appropriate clothing and exercise, are discussed in a sensible and helpful way. More space might have been devoted to the nervous factor and to asthma in childhood, and the brief mention of protein allergy, though calculated, is hardly wise.

## NEW INVENTIONS

### A RETROGRADE CYSTOSCOPE

FOR some years I have felt the need of a cystoscope which would enable me to see the hypertrophied prostate, as it projects into the bladder, from more or less the same angle as in an open suprapubic prostatectomy. In the modern suprapubic operation the first step, once the bladder has been opened, is to insert retractors in order to inspect the neck of the bladder, when with good technique a clear view is obtained of the projecting middle or lateral lobes, or both. Existing retrograde instruments were found to be quite useless for this purpose. I have submitted three separate designs to Mr. Schranz, of the Genito-Urinary Co., during the course of two or three years. The first two he refused to manufacture as impracticable; the third he undertook to make, and it has proved very successful in giving the desired information. With this instrument and with some practice in its use, the projecting middle and lateral lobes are clearly seen, and with further experience the degree of projection is readily recognised. The view obtained, while not quite that seen at suprapubic prostatectomy, is sufficiently accurate for practical purposes.

I am indebted to Mr. Schranz for the following description of the instrument:—

The new irrigating retrograde cystoscope is 21 Charrière in size and of conventional length. It is fitted with a double reflecting prism and lens system, which deflects the main axis through approximately 135°, so that the shaft of the instrument comes into view at the lower edge of the field. The image is corrected in a vertical

plane, but inverted in the lateral plane. With the patient in the lithotomy position and the operator facing the perineum, the patient's left side is on the operator's right. It has been found that this is less confusing to the operator when he is using a retrograde cystoscope. A flushing channel with inlet and outlet cocks is provided, with two apertures at the distal end. One of these is immediately in front of the objective and is fitted with a baffle which sends the stream backwards towards the internal sphincter. The other aperture is situated at the heel of the instrument.

With this instrument one can obtain a true retrograde view of the prostate very similar to that seen at open prostatectomy. It is hoped that with its use we may be better able to select cases for suprapubic prostatectomy or for resection, and may be in a position to study more exactly the relationship between frequency and intravesical projection of one or more lobes. Apart from its use with the hypertrophied prostate, the cystoscope has proved exceedingly useful in locating papillomata at the neck of the bladder. Using the present optical system, I hope in the near future to develop an operating instrument for dealing with these notoriously difficult tumours. I also hope to improve the water channels of the present examining instrument and to lessen the sharpness of the angle at the heel. In actual practice, however, the instrument has been found quite easy to pass and the present water channels are quite adequate for the clean or reasonably clean case.

T. J. D. LANE, M.D. Dub.

# THE LANCET

LONDON: SATURDAY, APRIL 4, 1936

## UNSCRUPULOUS ADVERTISING

It is not only the so-called trade-union of doctors which will be disappointed that the House of Commons failed to give a second reading to the Medicines and Surgical Appliances (Advertisement) Bill. The measure was blessed with an unusual volume of approval; its scope was carefully limited and its concessions were already substantial. It would, with the goodwill of organised newspaper interests, have prohibited a cruel and delusive form of advertising—the offer of positive cures for cancer, diabetes, Bright's disease and other named ailments, or for conditions such as amenorrhœa, hernia, blindness, and structural or organic defect of the ear. It would have forbidden the dangerous advertisements which offer to promote the miscarriage of women. It would have stopped the publishing of invitations to diagnose or treat the specified diseases by correspondence. All reasonable safeguards for bona-fide practice and treatment were already embodied in the Bill; had any others been deemed desirable, they could have been added in the usual process of improving proposals by amendment. But the legislative machine requires a quorum. After two hours of discussion on Friday, March 27th, the second reading was lost by default. There are 615 members of the House of Commons, but fewer than forty were present at 1.16 P.M. when the House was counted out. Sir ARNOLD WILSON, who moved the rejection of the Bill, agreed that some control of the vast development of advertising in relation to remedies and treatments was essential, that enormous frauds were perpetrated on the public, and that the loathsome atmosphere of fear was being created by a thousand advertisements. He had no objection to legislation; indeed, he promised a respectful reception if the Ministry of Health would produce official proposals. But he denied himself the opportunity of helping, here and now, to fashion an effective remedy. The opponents of the Bill seemed satisfied that its proposals were simply another obscurantist device for persecuting the unregistered practitioner and the herbalist, and for strengthening what is oddly described as the monopoly of orthodox medicine. The names of Sir Herbert Baker, Dr. Axham, and Mr. Spahlinger fitted across the floor of the House. The wastage of life through the ravages of the named diseases was deplored, of course; but the fact that medical research has not yet found a remedy for a disease was apparently deemed a reason for allowing quacks to guarantee cures by advertisement and correspondence.

The inadequacy of our existing law was thoroughly exposed in the convincing report of the Select

Committee of the House of Commons on Patent Medicines, published in 1914 and reproduced as a special supplement to THE LANCET of Jan. 10th, 1925. The Venereal Disease Act of 1917, which deals within its own limited scope with the very scandal which we are discussing, was not yet passed when that report appeared. Otherwise the legal position to-day stands much as it stood in 1914. The Dangerous Drugs Acts and the Pharmacy and Poisons Act, operated by the Home Office, hardly touch the particular problem. The Food and Drugs Act makes it an offence to sell an article under a label which contains a false description, but it goes out of its way to create a special exemption for a proprietary or patent medicine. Section 88 of the Larceny Act makes it a crime to obtain money by false pretences with intent to defraud; but the Assistant Director of Public Prosecutions had to explain to the Select Committee that charges under Section 88 were mostly useless because first it was generally impossible to prove wilful misstatement against the retailer, secondly, the defendant would probably produce witnesses who said the advertised drug had been beneficial to them, and thirdly, in grave cases (e.g., where drugs are sold to procure abortion) the victims of the fraud were not likely to come forward willingly. British law cannot prevent anybody from procuring any drug or advertising any mixture, whether potent or therapeutically valueless, provided it is not a poison or a narcotic, or a remedy for venereal disease, advertising it as a cure for any ailment, recommending it by bogus testimonials and the signed praise of fictitious physicians, and selling it under any name for any sum which a gullible public will pay. He may have to pay a small stamp duty, but even the Government stamp has been used to persuade the purchaser that it represents some kind of guarantee. Other countries have laws which take better care of their citizens. When Lord ASTOR introduced his Proprietary Medicines Bill in the House of Lords in 1920, he quoted the instance of an American, said to have made £60,000 by a campaign of selling in England a vibratory cure for various ailments, who, for just the same procedure in France, was sentenced in Paris to three years' imprisonment and was fined £120.

To return to the House of Commons, it would be imprudent as well as useless to scold at members; we want them to make amends some day soon. The recent Bill was unlucky in setting to sea on a Friday. Well as the private members in charge pleaded for it, it remained a private member's Bill. Gilbert's sentry sang of our legislators voting just as their leaders tell them to. There were no directions from above last Friday afternoon; it was nobody's business to "Keep a House"; the whips which cracked most invitingly were the whips at Aintree. The publication of the Select Committee's report unfortunately clashed with the World War in August, 1914. Mr. DUCKWORTH's excellent Bill unfortunately clashed with the Grand National in March, 1936. Let us not despair. The history of Parliament suggests that all reforms, great or small, take time. Perhaps

the Minister of Health will take Sir ARNOLD WILSON'S hint and introduce an official Bill. Or perhaps some medical officer will persuade one of our great municipalities to attempt legislation in advance of the backward standard of the rest of the country. Or perhaps again, since progress by catastrophe is a national habit, some pitiful tragedy of suffering and disillusionment will stir public opinion to put an end to this sinister union of falsehood and profiteering.

### CESTRIN, TUMOURS, AND THE PITUITARY

WE are now provided with fresh evidence on two current and important problems—the connexion between tumour growth and hormones, and the action of oestrin on the pituitary. This evidence suggests that (1) the female sex hormone, (2) the central gland of the endocrine system, and (3) the phenomenon of tumour growth must be thought of as closely related. The description by Drs. CRAMER and HORNING of the experimental production of pituitary tumours by oestrin, published in our issue of Feb. 1st, is this week followed by two papers in which Prof. B. ZONDEK and Prof. COLLIP and his colleagues record similar observations, all made independently.

Much investigation and speculation have been called forth by the recognition that oestrin is chemically related, though not intimately, to the carcinogens, and by the belief that substances with intense activity in promoting growth in certain tissues must bear some relation to the factors governing the growth of tumours. Oestrin has been found to be carcinogenic only in a special sense.<sup>1</sup> Unlike carcinogenic tars, or the synthetic carcinogenic hydrocarbons, it does not induce tumours at the site of application on the skin; the tissue which reacts to persistent overdosage is a tissue which possesses a specific physiological sensitiveness; and there must probably be an accessory activating factor. In LACASSAGNE'S experiments, and their repetition by CRAMER and HORNING, a race of mice was used with a high incidence of spontaneous mammary tumours in the females. Prolonged treatment with oestrin induces mammary development in the male, followed by growth of tumours, but, paradoxically, inhibits tumour development in the female. CRAMER and HORNING consider that either the female organism is able to destroy the excess of oestrin, or the carcinomatous response of the mammary epithelium depends on an indirect and not on a direct interaction between oestrin and the cells. The possibility immediately suggests itself that an indirect action might take place through the anterior pituitary, which is already established as an intermediary in some of the extrasexual effects of high doses of oestrin.<sup>2</sup> The influence of the pituitary hormones on tumours has been the subject of work carried out in Germany and America<sup>3</sup> which has shown conclusively the importance of this effect, but has not yet reached

the stage at which all the factors involved can be clearly distinguished. A group of American workers<sup>4</sup> claim to have observed an effect in the reverse direction in mice with spontaneous mammary tumours. These are associated with loss of gonadotropic activity of the pituitary and consequent atrophy of the gonads. The investigation of the direct oestrin-pituitary interrelation has made a striking advance with the latest observations of the effect of long-administered, large amounts of oestrin on the pituitary itself, and its bearing on the problem of malignant growths must now be worked out. CRAMER and HORNING found in three mice out of twelve a condition of hæmorrhagic chromophobe adenoma of the anterior lobe of the pituitary, and believe that they have produced experimentally the syndrome of Simmonds's disease. In the majority of the other animals the glands were macroscopically enlarged. The papers we publish this week record comparable observations in rats, but there are certain inconsistencies in the results which remain to be cleared up. Prof. ZONDEK observed simple increase in size of the pituitary only in male rats, whilst his single example of a pituitary tumour occurred in a female. On the other hand, Prof. COLLIP and his colleagues found enlargement of the pituitary, with occasional cavernous adenomata of the pituitary, in both males and castrated females, and refer to observations not published in detail showing that female rats are more susceptible to pituitary hypertrophy. It is to be hoped that systematic work will clear up discrepancies due to different experimental conditions. There is no doubt that these investigations are of first importance, for they will surely lead on the one hand to a better understanding of the ætiology of tumours, and on the other to a clearer view of the therapeutic possibilities and limitations of oestrin.

Attention may be directed to one point. It is only after isolation and chemical characterisation of the oestrogens and carcinogens that rapid advance has been possible with their biological investigation. The experimental pathologist must now ask the chemist to take on the admittedly harder job of clearing up the chemistry of the pituitary hormones.

### CANCER OF THE STOMACH

DOES early diagnosis of gastric carcinoma hold out any good hope of cure? Is a really early diagnosis possible? To these two questions physicians and surgeons in New York attempt an answer in a symposium published in the February issue of the *American Journal of Surgery*. The main points made by the contributors are that radiological methods have rendered accurate diagnosis fairly certain; that we must be prepared to suspect the disease on the appearance of such equivocal symptoms as "gastric consciousness" and abnormal tiredness after an ordinary day's work; that there are now a limited number of surgeons capable of performing gastric resection with a reasonably good chance of the patient's

<sup>1</sup> See THE LANCET, Feb. 8th, 1936, p. 324.

<sup>2</sup> Ibid., Jan. 4th, 1936, p. 7.

<sup>3</sup> Cf. a brief summary by H. Druckrey in Naunyn-Schmiedeberg's Arch. f. exp. Path. u. Pharmak., 1936, clxxx., 367.

<sup>4</sup> Allen, E., Diddle, A. W., Strong, L. C., Burford, T. H., and Gardner, W. U.: Amer. Jour. Cancer, 1935, xxv., 291.

surviving the operation; and that a few of the cases in which the growth is fungating (not infiltrating) stand a chance of five-year or ten-year cure.

Dr. JAMES EWING reports that a patient with one of the earliest gastric growths he has ever seen died of general abdominal carcinomatosis within sixteen months of gastric resection. What then are we to consider an "early carcinoma"? Dr. SEALE HARRIS quotes an opinion of McCARTY's that "no cancer in any part of the body is early if larger than a half a centimetre in diameter." In a cavity so big as the stomach there seems a poor chance of such a lesion being recognised. All the typical symptoms of cancer of the stomach are referable to ulceration, infection of the growth, or infiltration, causing obstruction of the lumen; and all these complications occur late. The idea that radiology will give earlier and earlier information is over-optimistic; but on the positive side Dr. GREGORY COLE points out that ulcerating lesions seen on the greater curvature are almost certainly neoplasms, never simple ulcers. An infiltrating growth attacks first the muscularis mucosa, and the effect of this is to straighten out the rugæ of the mucosa. The absence of rugæ is definitely recognisable in the barium-meal radiogram, and, combined with a localised obstruction of peristalsis and a lack of pliability of the stomach wall, has justified a diagnosis of cancer in cases in which the growth has caused no conspicuous deformity or obstruction of the cavity of the stomach. HARRIS assesses the value of the available laboratory tests, but finds none of any real help in the diagnosis; and the conclusion of the matter lies in the remark that a patient with stomach symptoms should ask not for a bottle of medicine but for an X ray examination. Abdominal discomfort rather than pain is generally held typical of early carcinoma; but, contrary to certain teaching, HARRIS considers that

periodicity of symptoms is not against the diagnosis. The pain he describes as being unrelated to meals but exaggerated by eating; and as usually occurring at night.

Figures are presented showing the results of treatment in 718 cases of cancer of the stomach in one hospital, of which 430 had an operation of one kind or another, most often merely exploratory or palliative. In 98 cases (13·6 per cent.) resection was carried out, and of these there were 65 in which the patient survived the operation. Ten were living without sign of recurrence after periods ranging from eight to forty-eight months; 9 were living at the end of five years; and 7 at the end of ten. The possibilities of radiotherapy are limited, partly by the inaccessibility of the organ, and partly by the fact that many gastric tumours are only slightly radiosensitive. T. PACK and ISABEL M. SCHARNAGEL, who report on this method of treatment, are not in favour of using it either as a prelude to operation or as a prophylactic against recurrence after resection. Of 60 patients regarded as inoperable who were treated either with radium, X rays, or both, 4 did really well and 6 were relieved to the extent of being able to resume work and enjoy life. The tumours occurring in the proximal half of the stomach are, it is stated, those most likely to be radio-sensitive; but they are also the least accessible to implantation of radium. A discussion at the end of the symposium raises the question whether more harm is done to the general cause of cancer cure by attempting operation and irradiation in advanced cases than would be done by allowing the patients to go home to die. It is suggested that deaths in hospital lead to prejudice against the treatment, and are not understood as being inevitable at the stage when the patient reaches the surgeon. This means that an important lesson is not learnt, and that more hopeful cases are deterred from seeking a remedy.

## ANNOTATIONS

### NEW STATUTES FOR OLD

MANY of the complaints against the bureaucracy of Whitehall arise from the confused state of a mass of laws for the creation and administration of social services—laws which involve interference with older ideas of individualism and which, while demanding the careful attention of the average citizen, are made more puzzling by indiscriminate and frequent amendment. The remedy is a periodical spring-cleaning of the statute book, and in this respect the Ministry of Health is to be praised for its activity. Having rewritten the poor-law enactments in 1927 and 1930 and the series of Local Government Acts in 1933, the Ministry has now produced the draft of a new code of public health which, when the Bill becomes an Act, will at last replace the Public Health Act of 1875 and its subsequent amendments. Not resting content with this achievement, the Ministry has also recently produced a Bill to consolidate the law of national health insurance (previously consolidated in 1924), another Bill to consolidate the law of widows', orphans', and old age contributory pensions (as yet hardly eleven years old), and yet another for the law

of housing (rewritten as recently as 1925). To these may be added two others, with which the Ministry is less immediately concerned—a consolidating Public Health (London) Bill, which is longer even than the proposed Public Health Bill for England outside London, and a Bill to consolidate the law of non-contributory old age pensions. These six Bills, all likely to be passed before the summer holidays, will place upon the statute book nearly nine hundred pages of tidy legislation. This tidying process is not an occasion for altering the nature of the law; alteration means controversy; a consolidation Bill enjoys exceptional facilities in passing through Parliament upon the condition that the new statutes merely replace the old. To attempt to introduce substantial amendments is to run the risk of wrecking the Bill. When it is safely placed upon the statute book, the task of amendment will be so much the easier. The changes made by the Local Government Act of 1929 could hardly have been formulated if the Poor Law Acts had not first been rewritten in simple and orderly form. The efforts of the Ministry of Health deserve the reward of success; they should inspire other departments to a like persistence in making plain the riddles of the law.

### THE RISKS OF BREECH DELIVERY

DURING the years 1913 to 1934 inclusive 30,655 patients were delivered on the house service of the Boston Lying-in Hospital, Massachusetts, and of these 1219 were delivered, through the pelvis, of 1242 infants by the primary breech mechanism. Dr. Thomas R. Goethals<sup>1</sup> has used this extensive material for an inquiry into the risk to the infant in breech delivery, which, it will be observed, occurred in a fraction under 4 per cent. of all patients. Of the 1242 infants thus delivered 922, or 74.3 per cent., left the hospital alive, 13.1 per cent. were stillborn, and 12.6 per cent. died in the neonatal period. Comparable percentages for all deliveries over 1924-34 were 6.2 stillbirths and 2.2 neonatal deaths, and this shows the big increase in risk to which the infant is exposed by the circumstance of breech delivery. A part of this high mortality is due to the fact that in over a fifth of the breech deliveries either the pregnancy was pathological—with such complications as pre-eclamptic toxæmia, eclampsia, nephritis, syphilis, or diabetes—or labour was complicated by such conditions as placenta prævia, ablatio placenta, or prolapse of the cord. The total mortality (stillbirths plus neonatal deaths) was in these cases as high as 52 per cent. compared with 18.5 per cent. in the uncomplicated breech deliveries. It might be argued that the risk of breech delivery per se should be assessed only from cases in which labour is uncomplicated, but it should be borne in mind that this series shows the incidence of placenta prævia, ablatio placenta, and prolapse of the cord to be respectively three, five, and five times as frequently associated with breech presentation as with all types of delivery. When from the uncomplicated breech deliveries those cases are excluded which resulted in the birth of macerated and grossly malformed infants and the remainder are taken as a standard for uncomplicated breech delivery, the total mortality was 13.6 per cent., this figure being derived from a rate of 53.6 per cent. for the premature, 10 per cent. for the immature, and 6.9 per cent. for mature infants. This last figure of 6.9 per cent.—based upon 691 deliveries—Goethals takes to represent “the risk to the living, undeformed, full term infant *in utero* who is destined to be born by pelvic breech delivery in the absence of pathological pregnancy on the part of the mother, and of hæmorrhagia and other accidents of labor due to abnormalities of the placenta or of the umbilical cord.” Prematurity was relatively common and contributed considerably to the mortality. Goethals takes the birth weight to the best standard and classifies an infant weighing less than 5 pounds at birth as premature, one weighing between 5 and 6 pounds as immature, and one weighing over 6 pounds as mature. In this classification approximately 20 per cent. of the breech deliveries were of premature infants, a figure which is more than three times as high as the 6 per cent. incidence of prematurity in the hospital deliveries at large. In mortality the breech deliveries did not differ from the general series until a weight of about 3 pounds is reached, but above that weight the breech deliveries suffer a substantially higher death-rate. In the breech-delivered the mortality is lowest with infants of 7½–8 pounds birth weight, and rises steeply on either side to 100 per cent. for infants of under 2 pounds, and to 33 per cent. for those over 10 pounds, the mortality of the latter being frequently due to maceration, malformation,

or to intercurrent causes rather than to an increased risk from mechanical causes.

Dr. Goethals can take satisfaction in concluding his statistical survey from the fact that in this series the mortality-rate among mature infants born by breech delivery has declined very substantially over the years of his review. His figures are set out clearly and fully and should prove helpful both in themselves and as a standard for comparison.

### JHIN JHINIA

THE *Indian Medical Gazette* for February publishes a lively account of a new “disease” which appeared last Christmas in Calcutta. There was one constant symptom—namely, a tingling sensation in the sole of one or both feet, usually in the big toe. This symptom—*jhin-jhin* in Bengali means tingling—gave the disease its name. Other symptoms were a feeling of pressure in the head with or without headache and a violent trembling of the whole body. The appearance of trembling was often delayed till treatment had been administered. According to local tradition, the disease was caused by a perverse tendency of the blood to desert the extremities and to fly to the head. The object of treatment was to reverse this process. The patient, male, or more often female, was accordingly tied to a post to prevent her lying down, and cold water was then poured over the head. Pneumonia was an occasionally fatal complication of the illness or, possibly, a sequela of treatment. Other grave sequelæ were meningitis, apoplexy, and fractured skull. The disease spread rapidly and seemed usually to attack persons in crowded places. Though it was sometimes misdiagnosed as encephalitis, meningitis, or Landry's ascending paralysis, complete investigation of cases admitted to the large hospitals in Calcutta revealed no organic lesions. The condition is therefore almost certainly a neuromimesis probably the result of mass suggestion among an illiterate populace. Opportunist “healers” were not slow to exploit the possibilities of the situation, and quack remedies and prophylactics found a ready sale. Local practitioners and health authorities are blamed, perhaps unfairly, for taking too serious a view of the “epidemic” in its early stages and the scare-mongering press for adding fuel to the fire. One peaceable citizen of Calcutta was seized by four men who accused him of having *jhin-jhinia*, soused him under a tap and departed with his wallet containing a hundred rupees. It seems a heavy price to pay for advice unsought.

### FILARIAL MIGRATION IN THE MOSQUITO

AT a laboratory meeting of the Royal Society of Tropical Medicine and Hygiene held at the Royal Army Medical College, Millbank, on March 19th, there was set out a series of microscope slides and photomicrographs prepared by Prof. F. W. O'Connor and Mr. Harry Beatty in the laboratory of Dr. James Knott, chief medical officer in the Virgin Islands. They illustrated what is believed to be a new observation regarding the behaviour of the larvæ of *Wuchereria bancrofti* in the mosquito *Culex fatigans*. It has been held hitherto that these larvæ force their way through the wall of the posterior, or saccular, part of the mid-gut (usually called the stomach) which lies in the abdomen of the mosquito, and that from there they make their way forward to the thoracic muscles where they undergo that development which is necessary before they again become infective for man. In these new investigations this was the

<sup>1</sup> Surg., Gyn., and Obst., March, 1936, p. 525.

behaviour of the larvæ for the first ten hours after the infective blood feed. But at the end of that interval they began to collect at the anterior end of the stomach, and shortly afterwards they passed into the anterior cylindrical portion of the mid-gut. Their forward transport went on, partly at least as the result of reversed peristalsis, till they were first distributed over the whole of this cylinder, and later, by the end of sixteen hours after the infective feed, had collected together to form a writhing mass just behind the valve which stops progress into the fore-gut. In one of the slides which was set out could be seen the first of two larvæ which was surprised in the act of forcing a passage through the wall of this anterior portion of the mid-gut into the thorax.

In another series of experiments O'Connor had shut up fed mosquitoes in glass boxes built up of microscope slides held together with plasticine, one mosquito being put into each box. The boxes were afterwards dismantled and the collected droppings examined. They showed a few healthy and dead microfilariae and their sheaths. But if these larger objects can be passed by mosquitoes, there is little doubt that blood corpuscles and plasma are passed much more freely. Moreover it is the case with blood-suckers so different as fleas and hookworms that passage of blood elements begins while the feed is still going on, so that it is reasonable to suggest that it may be found to do so in these mosquitoes if they are allowed to go on feeding undisturbed. In such conditions the number of microfilariae which a mosquito will swallow and retain at one feed will be larger than the number of them contained in that quantity of blood which will fill its stomach once, and this quantity will not measure the degree of infection which the insect risks. O'Connor's investigations continue to shed needed light on filarial infection and to show that each fresh advance brings into view fresh problems calling for solution.

### HYSTEROSCOPY

THE technique and possibilities of hysteroscopy are described in an interesting paper<sup>1</sup> by Prof. Hamant and Dr. Durand. The first account of this procedure was given by Aubinais in 1864 and since that time various methods have been proposed though they have usually been received with little enthusiasm. Hamant recommends the use of the instrument designed by de Segond, which, in principle, is constructed like the urethroscope. Contra-indications to hysteroscopy are few and obvious; the operation should not be attempted when there is inflammation in the pelvis, pregnancy, or profuse uterine bleeding. It may be done under general or local anæsthesia, and with the patient in the lithotomy position a full aseptic technique is used. Sterile water is used to wash out the uterus and endoscopy is performed when the uterine cavity is distended by a pressure of about 650 mm. of water. The work of Schroeder has shown that water does not pass from the uterus to the Fallopian tubes at a pressure of 950 mm. of water, or 40-45 mm. of mercury. Hamant advises that the usual biopsy should always accompany hysteroscopy. That the method has considerable value as an aid to diagnosis is proved beyond dispute by his excellent illustrations. Whereas the curette is very useful as an aid to diagnosis, no one will deny that this instrument can fail upon occasion to

detect a small malignant ulcer, or to remove a small fragment of chorionic tissue or even a large endometrial polyp.

### PROBLEMS OF THE FAMILY

MUCH attention has been devoted to population problems in recent years. In a special memorandum (No. 40) published by the London and Cambridge Economic Service,<sup>1</sup> Dr. Enid Charles furnishes us with three estimates of the future size of our population depending upon three hypotheses: (1) that fertility- and mortality-rates from 1935 onwards will continue to be the same as they were in 1933, this being the most recent year for which the necessary data are available; (2) that the fall in fertility- and mortality-rates which has occurred in recent years will be continued into the future; and (3) that fertility-rates will rise to the level of 1931 (i.e., roughly 10 per cent. higher than in 1933), while mortality continues to fall. While it is unlikely that the actual movement of our population will coincide exactly with any of these three estimates, it is probable that the second will be most closely realised by future events. What then would be the effect upon our population if recent trends of birth- and death-rates were to be continued into the future? Briefly, the population will reach a maximum of about 41 million in the year 1940, after which it will begin to shrink. The decline will, at first, be slow. By the year 1950 the population would be but little smaller than it is to-day, but the age composition would be very different. There would be relatively more old people and fewer children. By the year 1965, a generation hence, the population would have fallen to 36 millions; by 1975 to 31 millions; and by the year 2000 to 17 millions. The decline would gain momentum each year, and a hundred years hence, in the year 2035, the population would have dwindled to about 4½ millions—a figure rather smaller than the present population of Greater London. In the last year the trends of previous years have been slightly reversed. The birth-rate has gone up by a fraction of a point in response, it is supposed, to an increased marriage-rate fostered by the recent improvement in economic conditions. What is the birth-rate going to do in the next few years? At its present level, it appears to have fallen to about 75 per cent. of replacement rate. Dr. Charles calculates that the net reproduction rate for 1933 is 0.734; if this rate continues below unity, we are confronted with an inevitable decline in the population. What are the prospects of its being raised?

The figures in Dr. Charles's numerous tables and the direction of the curves on her carefully prepared charts depend upon intimate events occurring within the family. A comprehensive and detailed study of these changes was published in 1934 by Prof. K. Folsom<sup>2</sup> in a book which, in his words, "attempts to weave cultural anthropology, individual psychology, social psychology, history, sociology, economics, and psychiatry into a unitary *science of the family*." In this ambitious scheme the family unit is examined from every standpoint and the conclusion is reached that its future evolution will be determined by two major groups of cultural changes. These are our mechanical inventions whose general social effect is increased machinery, urbanisation, and higher material

<sup>1</sup> Obtainable from the London School of Economics, Houghton-street, Aldwych, W.C.

<sup>2</sup> *The Family—its Sociology and Social Psychiatry*. By Joseph Kirk Folsom, Professor of Sociology, Vassar College. New York: John Wiley and Sons; London: Chapman and Hall. Pp. 604. 25s.

<sup>1</sup> Hamant, A., and Durand, E.: *Rev. franç. de gyn. et d'obst.*, January, 1936, p. 1.

standards of living, and our discoveries in biological and psychological sciences which, by displacing the theology of the Victorian era, have led to an unprecedented individuation of the personality. Folsom prophesies that, in the comparatively near future, reproduction will, in civilised countries, come to be completely and universally controlled. The solution of the other problems associated with the future of the family, however, will depend upon our cultural ideology, upon the possibility of international peace and of economic stability. Civilised countries may evolve in the direction of liberalism, which places its highest value upon the development of the individual personality; or it may take what he calls an anti-liberal direction as it has done in Japan and in those European countries which have adopted fascism. He is optimistic about the future of the family if liberalism finally prevails, as he hopes it will. Chapters follow on the cultural history and geography of the family, the effect on it of social change and family mass readjustments, and individual adjustments as they affect family problems. Perhaps the most interesting part of the book is the analysis of how the four essential problems relating to the control of reproduction, the economic foundation of the family, the mate-to-mate relationship, and the parent-to-child relationship are resolved in the cultural organisations of different races and countries.

#### PAIN IN PSYCHOPATHOLOGICAL CONDITIONS

PHYSICAL pain is like fear in that many of us have felt it only in its milder forms, and, if we are doctors, learn to contemplate it in others with a detachment that would be callous if it was not associated with confidence of our ability at least to relieve it by anodynes if not to cure it. We are apt, moreover, to think of physical pain as a relatively simple matter of sensations and nerve tracts which can be understood on physical lines. The psychogenic production of pain and the varying sensitivity to it in different individuals, or in different states of mind in the same individual, are among the many interesting aspects of the subject on which Dr. Macdonald Critchley touched in the twenty-fourth Long Fox memorial lecture.<sup>1</sup> It is evident from his exposition that the questions raised by pain are complex and bring up fundamental issues in psychopathology. As he points out, the disputes as to the "reality" of psychogenic pain are usually sterile exercises in casuistry, but the elucidation of the mechanism of such pain is none the less a necessary task. Dr. Critchley mentions a patient with causalgia, repeatedly and fruitlessly mutilated by the surgeons, even to chordotomy, who might well serve as an object lesson in the need for further study of the neurological and psychological basis of pain. It is curious that suicide is seldom resorted to as an escape from continual pain. Dr. Critchley remarks on a fact which is the converse of this—viz., that depressed people, in whom suicide is frequent, often show striking indifference to pain. It is, however, difficult to be sure whether this apparent indifference is not a stoicism that masks a perception as acute as that of more normally demonstrative people. There are many ways of reacting to pain, as J. D. Achelis<sup>2</sup> has pointed out. The depressive with his ideas of self-reproach may bear without complaint, may even welcome, bodily pains: many such patients say how gladly they would exchange their mental torment for some corporeal distress. Some of them

also have morbid proclivities, often masochistic in nature, which influence their conduct. The behaviour of depressive patients, especially when operations or painful dressings are necessary, does not bear out the view that their sensitivity to pain is lowered, even though the unpleasantness of the affect accompanying the pain is swallowed up in their larger misery. The interesting researches of H. Piéron<sup>3</sup> bear on this point. J. Schröder,<sup>4</sup> moreover, reported instances of manic-depressive psychoses in which pain played a large part. It is not necessary that pain should be consciously experienced whenever it is acutely felt. Thus in alcoholics, with deep clouding of consciousness, L. Bender and P. Schilder<sup>5</sup> have observed an increased sensitivity to pain, so that they conclude (paradoxically) that the somatic apparatus of consciousness has a protecting influence against pain: when consciousness is clouded and cortical activity greatly lessened, pain seems to sweep over the whole body instead of being localised. It would be an advance of great profit to psychiatry as well as to neurology if the nexus between cortex and sub-cortical centres, especially thalamus, could be further elucidated in its psychological implications, such as this problem of pain.

#### MORE TUMOURS OF THE ISLETS OF LANGERHANS

FIVE cases of severe spontaneous hypoglycaemia came under the care of the Neurological Institute in New York within 16 months, and in all of them tumours of the pancreatic islets were found and removed and the patients restored to health. The physicians concerned have reported them at length.<sup>6</sup> The clinical picture is distinctive and ought to be recognisable by a doctor of average experience who has read about it and not forgotten what he has read. The patients were adults, suffering for months or years from paroxysmal attacks of mental and physical disturbance lasting hours or even days. They sometimes became unconscious, often just confused, restless, irritable, or negativistic; they showed superfluous movements, tic-like, semi-purposeful, or bizarre; and objective neurological signs such as diplopia, nystagmus, and extensor plantar responses were sometimes noted. Profuse sweating characterised them all. Attacks often came on when the patient was fasting, and were alleviated by taking of food. Blood-sugar levels between 30 and 50 mg. per 100 c.cm. were usually found, and intravenous glucose gave temporary relief. While it seems clear that the symptoms are due to an excess of insulin activity, their mechanism is still obscure. The relation between blood-sugar level and cerebral disturbance is by no means constant, either from patient to patient, or from time to time in a given patient, and it is difficult to understand why the attacks should be paroxysmal with long intervals of comparative freedom.

The surgeons have also published their account of these cases,<sup>7</sup> prefaced by an admirably concise historical review. They find now 31 recorded examples of spontaneous hypoglycaemia with pancreatic tumours, nearly always adenomata and only rarely carcinomata of the islets. They also find 18 cases where an expected tumour was not found,

<sup>2</sup> Zeits. f. Psychol., 1924, lvi., 31.

and on the other hand 31 cases of such tumours found incidentally post mortem in the absence of suggestive symptoms. Some useful recommendations are made as to procedure in suspected cases. The diagnosis should be made in the first place from the history and the demonstration of hypoglycæmia; if it is supported by the occurrence of symptoms during 24 hours' starvation and their relief with intravenous glucose, then operation is advised. Spinal anæsthesia, a transverse incision, and complete exposure of the pancreas are recommended. The tumour is likely to be a purplish nodule half an inch or less in diameter, on the anterior or the posterior aspect of the pancreas, and there may be two of them. Body and tail are commoner sites than the head. Shelling out the tumour is usually easy, but if no tumour is found excision of two-thirds of the pancreas is to be undertaken, and that is naturally more difficult. Tying the splenic artery and removing the spleen as well may facilitate it. This large partial pancreatectomy has relieved symptoms in some recent cases, but even the most eager surgeon will still welcome the finding of one or two well-defined adenomata, and the almost certain prospect of cure that their removal will bring. It may be that these cases are commoner than we think; it rests with the general practitioner and the physician to recognise them and give them the chance to be treated.

#### DIAGNOSIS AND PROGNOSIS IN POLIOMYELITIS

RECENT outbreaks of poliomyelitis in Denmark have led to some interesting studies of this disease by the Danes, whose public health administration is singularly well fitted for the task. Dr. N. I. Nissen<sup>2</sup> gives an account of 132 cases of poliomyelitis treated in the Blegdam Fever Hospital of Copenhagen during 1934. During the latter half of that year no fewer than 316 patients were admitted to the hospital with the diagnosis or query of acute anterior poliomyelitis, but only in 113 of them could this diagnosis be maintained. It is obvious from these figures that it is very difficult to distinguish early poliomyelitis from the many other ailments which may simulate it. In as many as 56 of Nissen's cases the diagnosis was reduced to angina faucium, and this was the final diagnosis in another group of 66 patients, although there was a suspicion of spinal rigidity in the clinical picture. In 21 cases the diagnosis was reduced to that of acute gastro-enteritis, while 16 patients were found to be suffering from influenza with conspicuous catarrhal symptoms, and 10 from pneumonia. Various other diseases such as arthritis, tuberculous meningitis, and bronchitis masqueraded in the early stages as poliomyelitis. No wonder, therefore, that Nissen writes: "Often it has been very difficult, and sometimes altogether impossible, to make the differential diagnosis between mild and abortive cases of poliomyelitis and, in particular, the numerous mild cases of angina and fever that are admitted here to the Blegdam Hospital throughout the year." It has been found that in Denmark, as in several other countries, there has been a definite and regular upward shift in the age-distribution of the disease. No similar shift in the age-distribution of diphtheria, scarlatina, measles, and influenza has been observed during the past fifteen years, and Dr. Nissen is at a loss to account for it. With regard to the prognosis in cases in which paralyses have not yet occurred, he has sought by a statistical analysis to discover signs which would enable the clinician to forecast the subsequent course. Though

he can find no one sign or symptom of uniformly reliable prognostic value, he has come to the conclusion that paralyses are most probable when the illness is characterised early by drowsiness, restlessness, shivering, tremor, excessive sweating, and muscular tenderness. It is also of bad omen when the disease runs a diphasic course—i.e., one with a distinct primary febrile reaction followed by a symptom-free latent period which in its turn gives place to meningeal signs.

#### ADDENDUM TO THE B.P 1932

THE General Medical Council, on the recommendation of the British Pharmacopœia Commission, have arranged for the publication during the present year of an addendum to the British Pharmacopœia of 1932. General revision has led to several alterations in detail of description and method, and in addition the addendum will contain monographs on numerous new remedies introduced during the last four years. In order that the addendum may have the advantage of public criticism before it is officially adopted, the principal recommendations and emendations suggested by the various committees in charge of revision are now being circulated in pamphlet form. The clinical committee regrets that the law of patents has prevented the inclusion of certain drugs, and this no doubt explains the omission of such substances as the organic mercurial diuretics. Among the more important drugs recommended for description are liquor iodi aquosus ("Lugol's iodine"), oleum iodisatum, argentoproteinum, sodii thiosulphas, tryparsamidum, histaminæ phosphas acidus and ergometrina. Five new antitoxic sera are included—namely, gas gangrene (œdematiens), gas gangrene (vibrio septique), staphylococcal and pneumococcal (Types I. and II.). Calciferol (vitamin D) is to replace irradiated ergosterol, and ascorbic acid (vitamin C) is described. A standardised preparation of vitamin B<sub>1</sub> is to be included. The pamphlet merits careful perusal by all interested in pharmacology or therapeutics.

#### CONSTITUTION AND DISEASE

Two further studies on constitution in relation to disease have lately been published by Prof. Raymond Pearl and his colleagues working in the department of biology of the School of Hygiene and Public Health, Johns Hopkins University. The first comprises a statistical analysis by Antonio Ciocco of data concerning 126 white women with heart disease<sup>1</sup> and is a sequel to Pearl and Ciocco's analogous study on white men.<sup>2</sup> As a comparative group the author takes 37 female patients (a regrettably small number) who at the time of their examination gave no clinical evidence of cardiac disease. The general conclusion that can be drawn from his data is that as a group the women with heart disease are characterised by greater body-weight associated with greater chest and especially greater umbilicus girths. It will be recalled that the same feature was observed in the earlier study on men. In stature and correlated vertical dimensions the "cardiacs" and "non-cardiacs" show no material differences. A higher proportion of the cardiacs are classified as pyknics and a lower proportion as asthenics, but their superiority over the non-cardiacs in weight and correlated horizontal dimensions appears to be independent of somatic type, since in each group, pyknic, intermediate, and asthenic, the cardiacs have the higher average weight and chest girth. In their earlier study on males

<sup>1</sup> Acta med. Scand., 1936, vol. lxxxviii., Fasc. I.

<sup>2</sup> Human Biology, February, 1936, p. 38.  
<sup>3</sup> Ibid., 1934, vi., 650; see THE LANCET, 1935, i., 242.

Pearl and Ciocco suggested that the differences might be a consequence of relative over-eating and lack of physical exercise. Ciocco has tried to gain information on this point by questioning the women about appetite and regularity of bowel movement. The proportions of cardiac and non-cardiac patients who admit eating heartily, average, or sparingly do not differ, but a higher proportion of the cardiacs complain of irregular bowel movements or chronic constipation. These two facts taken in conjunction strengthen the hypothesis. Ciocco suggests, that the accumulation of fat in the cardiacs may be in part the effect of dietary habits not in keeping with their physical activity. Clearly there is no proof that this relative overweight is an aetiological factor in heart disease, but it is of some interest in view of the beneficial effect in some cases of restricted diet and consequent reduction of weight. In addition to the detailed statistical analysis of his two groups, Ciocco includes anthropometric measurements of women with various diseases taken from several published sources, which may prove useful to workers in this field.

The second study,<sup>3</sup> by Raymond Pearl, Marjorie Gooch, John R. Miner, and Walter Freeman, is a continuation of the author's earlier work on the relation of the endocrine organs to mental disease.<sup>4</sup> The object of the present analysis is to determine whether the endocrine organ weights individually, or the general endocrine system pattern, are differentiated quantitatively in the asthenic, intermediate, and pyknic body types, with a fourth group made up of individuals not falling precisely into these so-called "pure" types, labelled dysplastics, and of somewhat doubtful content. All measurements were, it will be remembered, taken at autopsy. As would be expected, there is a clear tendency for the average weight of the endocrine organs to increase as we pass from asthenics to intermediates and to pyknics. As the average body-weight increases from habitus group to group the average weight of all the endocrine organs tends also to increase. Does the latter increase when body-weight is taken into account, or put in other words, do the pyknics, on the average, carry a greater or smaller dosage of endocrine organ tissue than do the asthenics per kilogramme of total body-weight? The authors' answer to this question is quite definite. Uniformly in each of their groups (males, females, white, and negro) they find that the average quantitative dosage of endocrine organ tissue per kilogramme of body-weight is greatest in asthenics, less in intermediates, and least in pyknics so far as concerns adrenals, thyroid, parathyroids, hypophysis, epiphysis, and gonads, while in the relative dosage of thymus tissue the order is reversed, being least in asthenics, greater in intermediates, and greatest in pyknics. The differences between the two extreme types, asthenic and pyknic, are generally large in amount and thus reveal an interesting association between the quantitative endocrine system on the one hand and the bodily habitus types on the other.

### ILLICIT TRAFFIC IN NARCOTIC DRUGS

VALUABLE evidence of the extent of illicit manufacture and traffic in narcotic drugs is furnished by a report to the League of Nations by the Secretariat. The report summarises the amounts of the various drugs seized in each country during 1934 as well as details of seizures and the discovery of clandestine manufactories during the latter part of 1935. The

total seizures of raw opium in 1934 exceeded 34,170 kilogrammes, the largest amounts being in French Indo-China, Soviet Russia, and Burma; 8064 kg. of prepared opium were seized, more than half having been found in the Netherlands; 236 kg. of morphine were confiscated, Turkey, China, and Egypt yielding the chief contributions. Nearly 500 kg. of heroin were seized largely in Shanghai and Hong-Kong. Of cocaine some 117 kg. were seized, Burma and the International Settlements of China reporting the highest figures. It was in the last-named area in Shanghai that four clandestine factories were unearthed. The culprits, who were Chinese nationals, were prosecuted and fined or imprisoned, or both, the heaviest sentence being two years imprisonment and a fine of 300 Shanghai dollars. So far as information is furnished for the year 1935 it would appear that the amount of illicit traffic, as judged by seizures made, was less than was the case in 1934.

### A FINAL LECTURE

Mr. H. A. T. Fairbank, in giving his final lecture last week as senior orthopaedic surgeon to King's College Hospital, chose to speak impromptu on some general diseases of the skeleton. It was the kind of lecture that students do not often get; they are supposed by examiners to know about developmental errors many of which they do not get a chance of seeing. Mr. Fairbank circulated a list of over sixty such conditions, although he dealt in his address with only a few of the more common ones. The lecture was illustrated by lantern slides, and at its conclusion the lecturer was presented with a silver replica of the splint which bears his name. More than this, the theatre was decorated with streamers, and to reach it Mr. Fairbank was compelled to walk through a triumphal arch of human bones and splints.

THE King has consented to become patron of the Royal Medical Benevolent Fund.

THE second International Congress for the Protection of Infancy will be held in Rome in the early part of October, immediately following the sessions of the fourth International Paediatric Congress.

WITH the death of Sir JOSEPH PETAVAL at the age of 62 years we lose a physicist of singular practical acumen. Sometime professor of engineering in Manchester University and director of the Whitworth Laboratories, in 1919 he succeeded the late Sir Richard Glazebrook as director of the National Physical Laboratory at Teddington. His contribution to aeronautical research was outstanding. He was an original member of the National Radium Commission.

THE Medical Research Council have appointed Sir Patrick Laidlaw, F.R.C.P., F.R.S., to be deputy director of the National Institute for Medical Research, and head of the department of pathology and bacteriology there, in succession to the late Captain S. R. Douglas, F.R.S. Sir Patrick has been a member of the council's scientific staff at the National Institute since 1922. He has latterly been engaged chiefly in the investigation of diseases due to ultramicroscopic viruses. His success as leader of the team of workers who solved the problem of securing immunisation of dogs against distemper and subsequently discovered the virus of epidemic influenza will be fresh within the recollection of our readers.

<sup>3</sup> Human Biology, February, 1936, p. 92.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

XCV.

### PROGNOSIS OF ACUTE POISONING

IN Great Britain and the United States of America carbon monoxide outnumbers all the other poisons combined as a cause of fatal acute poisoning. The great relative frequency and gaseous nature of this poison entitle it to primary and separate consideration. The other common poisons causing dangerous poisoning in civil life are all liquids or solids.

#### Carbon Monoxide

Most fatal cases of carbon monoxide poisoning are suicidal, but this insidious gas claims many victims as the result of accidental inhalation. Its common sources are illuminating gas, exhaust gases from motors, and coal gas from stoves and fires. Carbon monoxide is poisonous because it combines with the hæmoglobin of the blood to the exclusion of oxygen. Otherwise it is physiologically inert. The gassed patient suffers simply from anoxæmia, and his state of oxygen-lack may be as severe as that of blue-black victims of obstructive asphyxia. The bright complexion of these patients is deceptive, being due to the red colour of carboxy-hæmoglobin.

There is no question as to the lethal quality of carbon monoxide and many men or women exposed to it are dead when discovered. On the other hand, many are only slightly or moderately poisoned and soon recover when removed from the contaminated atmosphere. Interest in regard to prognosis centres on the intermediate group of cases which are dangerously poisoned and whose lives hang in the balance. These are easily recognised because they are always unconscious or on the verge of coma—i.e., collapsed and stuporose. The inexperienced observer may be misled by their appearance which is by no means alarming. Not only is the colour good, but the breathing, owing to anoxic depression of the respiratory centre, is unobtrusive. The picture of a pink, quietly breathing, and apparently slumbering patient may well deceive the observer with tragic consequences. If a gassed patient cannot be roused his life is in jeopardy; without prompt treatment many such patients die.

The immediate prognosis in serious carbon monoxide poisoning has been radically changed since the introduction in 1922 by Henderson and Haggard of the carbon dioxide-oxygen method of treatment. It is now almost true to say that no case, however deeply gassed, discovered alive and efficiently treated will die. The treatment consists in the continuous administration, by means of a mask and bag, of a mixture of 7 per cent. of carbon dioxide and 93 per cent. oxygen. In patients whose breathing is greatly depressed the administration is started with artificial respiration by the Schäfer prone-pressure method. The powerful stimulus of the carbon dioxide to the respiratory centre soon causes a remarkable increase in breathing, and this combined with the inhalation of oxygen in place of air very greatly speeds up the displacement of carbon monoxide from the blood by oxygen.

Most patients recover consciousness within an hour under the carbon dioxide-oxygen treatment, but those who are very gravely ill may remain unconscious for days. Such prolonged unconsciousness is not due to poisoning, since little carbon monoxide remains in

the blood after an hour's hyperventilation with oxygen. The continuous coma is due to damage done to the nervous system by the profound anoxia before treatment was begun. Treatment must always be prolonged until normal breathing is not only established but sustained. Furthermore, all victims must be carefully watched for many hours after cessation of treatment as respiratory depression may return and the patient may relapse; in fact there may be recurrent relapses, any one of which may prove fatal if the patient is left unattended.

Very few patients after recovery of consciousness experience anything worse than a few days of malaise with headache, dizziness, and nausea. In an extremely small proportion the acute poisoning is followed immediately or in one to three weeks by mental or nervous sequelæ. The commonest mental sequela is a confusional psychosis; the commonest nervous sequela is a parkinsonian condition.

#### Swallowed Poisons

According to the annual statistical reviews of England and Wales by the Registrar-General deaths from swallowed poisons are due, in order of frequency, to the following agents: phenol and phenolic disinfectants; corrosive acids and alkalis; prussic acid and cyanides; oxalic acid and oxalates; various narcotic and analgesic drugs—opium derivatives, barbiturates, and aspirin; strychnine and nux vomica; arsenic; mercury salts; phosphorus; atropine and belladonna.

The prognosis in acute poisoning by any of these poisons must mainly depend upon the nature of the poison and the amount of it which has been ingested and retained. Academic discussion of the relative toxicities and lethal doses of these poisons is likely to be of little service to the practitioner confronted only very rarely with a case of poisoning. Such infrequently used data eludes the memory in an emergency. Moreover, such considerations neglect the fact that in practice one does not often know precisely what the patient has taken or how much of it. Patients who have taken sub-lethal doses will recover; the important practical point is whether or not a particular person who has *probably* swallowed a lethal dose of poison can or cannot be saved. His chances of survival depend upon the possibilities of: (a) removal or neutralisation of the poison; (b) counteraction of such effects of it as are immediately endangering life.

#### REMOVAL OR NEUTRALISATION OF THE POISON

The possibility of removal of the poison must be greatly influenced by the time which has elapsed before the case is seen. The hope for the patient varies inversely with the delay in beginning treatment. But even if many hours have elapsed eliminative treatment should not be neglected. Gastric lavage is the method of choice, except in the corrosive cases, and properly performed is most effective. If the patient is seen within an hour or two the thoroughness with which the stomach is washed out is the chief factor in the prognosis so far as treatment is concerned. Two gallons of water should be used, a pint at a time being run into the stomach. Such thoroughness is almost impossible unless the patient is placed in a proper position—i.e., with the mouth and pharynx on a lower level than the larynx and trachea—so that fluid regurgitated around the stomach-tube does

not enter the air-passages. This point, of paramount importance, does not appear to be mentioned in most text-books. Attempts to carry out a stomach wash-out with the patient in an unsuitable position (lying on the back or sitting up) lead in conscious cases to great distress and coughing and spluttering, while in comatose cases with absent cough reflexes immediate death from drowning or later death from broncho-pneumonia may result. Many an unconscious patient must have been killed in this way who might have survived had nothing at all been done to him. The most convenient suitable position of the patient for general use is lying *prone* upon a couch, bed, or table with the head, supported by an assistant, projecting over its end, the face directed and bent towards a bucket on the floor. The operator sits or kneels on the floor while passing the tube. Prolonged lavage with the patient in this position is an easy and safe procedure.

The only swallowed poisons for which gastric lavage is contra-indicated are the corrosive acids and alkalis (sulphuric, nitric, and hydrochloric acids, and caustic soda, caustic potash, and strong ammonia). The phenolic disinfectants and oxalic acid are corrosive, but not sufficiently so to preclude lavage. The corrosives should be neutralised by the administration of weak alkalis or acids. In my opinion the only condition in which neutralising antidotes are of much practical importance is when they are used against corrosives. With other swallowed poisons thorough mechanical removal by lavage is of much more value than is any attempt to render the poison inert.

#### COUNTERACTION OF IMMEDIATE DANGERS TO LIFE

There are only five common modes or mechanisms by which life is primarily endangered in acute poisoning: (1) asphyxia; (2) depression of the central nervous system—i.e., coma; (3) dehydration and de-

chloridation; (4) pain and shock; (5) excitation of the nervous system—i.e., violent delirium or convulsions.

The omission of circulatory failure from this list demands some explanation. Very few poisons seriously injure the circulatory system as a primary effect. Circulatory failure may be the almost invariable final mode of death, but it is secondary to one or more of the above-named effects.

From the point of view of prognosis it is fortunate that these five dangerous conditions are easy not only to diagnose but to treat. *Asphyxia* is effectively treated by clearing the patient's air-way, doing artificial respiration, and the giving of oxygen and/or carbon dioxide. *Toxic coma* is not quite so easily controlled, but luckily its seriousness is often largely due to coexistent asphyxia from respiratory obstruction or depression. The administration of strychnine and coramine in really large doses (i.e., strychnine grain  $\frac{1}{2}$  and coramine 5–15 c.cm.), repeated as often as once every hour, is very valuable in deep coma; so also is repeated lumbar puncture as advised by Willcox and Purves-Stewart. *Dehydration and dechloridation* from vomiting and diarrhoea is the lethal factor in cases of poisoning by the gastrointestinal irritants. Continuous intravenous drip saline therapy should completely abolish this cause of death. *Pain and shock* due to pain can be controlled by morphia. *Delirium and convulsions* are now controllable by the use of barbiturates such as pernocton.

The considerable efficacy of treatment, both in eliminating poison and counteracting lethal effects, in acute poisoning due to swallowed poisons justifies the statement that in most patients seen before they are actually moribund the chances of survival are very good.

H. L. MARRIOTT, M.D., M.R.C.P.,

Resident Medical Officer, the Middlesex Hospital, London; Assistant Physician, the Miller General Hospital, Greenwich.

## THE SERVICES

### ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. T. Gwynne-Jones and Surg. Lt. (D.) A. C. Horne lent to N.Z. Division for three years (*Achilles*, on recommg.).

Surg. Comdrs. W. A. Hopkins to *Excellent* and F. L. H. MacDowel to *Repulse*.

Surg. Lt.-Comdrs. R. G. Anthony, J. G. Holmes, and E. R. Sorley to rank of Surg. Comdr.; J. G. Currie to *Royal Sovereign*; and R. B. McVicker to *Tamar*.

Surg. Lt. W. Greaves to rank of Surg. Lt.-Comdr.

Surg. Lt.-Comdr. (D.) L. R. Armstrong to *Drake* for R.N.B.

### ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. G. C. Martin to *Excellent*.

Proby. Surg. Lt. A. V. Griffiths to *Royal Sovereign*.

Surg. Sub-Lt. T. D. R. Aubrey promoted to Surg. Lt.

### ROYAL ARMY MEDICAL CORPS

Short Service Commissions: Lt. (on prob.) J. H. Caverhill is restd. to the estab.

### ROYAL AIR FORCE

Wing Comdr. T. J. Thomas to Headquarters, Fighting Area, Uxbridge, for duty as principal medical officer.

### INDIAN MEDICAL SERVICE

Col. I. M. Macrae, C.I.E., O.B.E., Ind. Med. Serv., V.H.S., is apptd. Hon. Physician to the King vice Maj.-Gen. T. G. F. Paterson, C.B., D.S.O., Ind. Med. Serv., ret.

Lt. (on prob.) C. W. A. Searle is restd. to the estab.

### DEATHS IN THE SERVICES

The death occurred at St. Briavels, Gloucestershire, on March 13th, of Surg. Capt. OCTAVIUS WILLIAM ANDREWS,

C.B.E., R.N. ret'd. Born in 1865, the son of Dr. H. C. Andrews, he was educated at Bishops Stortford, Durham University, and St. George's Hospital, London, and qualified M.B. Durh. in 1887. He entered the Navy in 1889, being surgeon of *Ringdove* from 1891 to 1894. In 1898 he was sent to the Pasteur Institute at Paris and was then appointed to *Tamar*, Receiving Ship at Hong-Kong. Later he was fleet surgeon of *Diana* when he made a "Report on the Island of Cyprus." In 1913 he retired with the rank of surg. capt. but was recalled and took part in the European War from 1914–19, being mentioned in dispatches and created C.B.E. (Mil.) in 1919 as well as an officer of the French Legion of Honour. In 1894 he wrote a "Report on Leprosy and Depopulation in the South Pacific Islands," and later "Seamarks and Landmarks." For his public health work he was awarded the Chadwick gold medal.

The death occurred on March 7th of Surg. Commander JULIAN LIONEL PRISTON, R.N. He was born at Gillingham, Kent, in January, 1892, son of Engineer Rear-Admiral R. B. Priston. He received his medical education at the London Hospital, qualified M.R.C.S. Eng. in 1914, and in April of that year entered the Navy as surg. lt., serving at the Naval Hospital, Plymouth. After the war he graduated M.B., B.S. Lond.; he took the D.P.H. in 1922, and became F.R.C.P. Lond. in 1926. In 1920 he became assistant pathologist at the R.N. College, Greenwich, where he worked on the germicidal efficiency of certain antivenereal prophylactics and the reaction of the blood in health and disease, being awarded the Gilbert Blane gold medal in 1923. Later he was transferred to the medical department of the Admiralty as assistant for hygiene duties to the director-general. Since 1933 he had served at the Royal Hospital, Chatham.

## SPECIAL ARTICLES

## IN HONOUR OF ALMROTH WRIGHT

ON Tuesday of last week a graceful tribute to the work of Sir Almroth Wright was paid when he was presented with a bust purchased with subscriptions from those who over many years have admired the untiring persistence and great results of his work. The presentation was made in the library of the medical school of St. Mary's Hospital before a large and representative gathering, and Sir HENRY DALE before unveiling the bronze, which is to stand in the inoculation department of the hospital, spoke in eloquent and intimate manner of the debt owed by the world to Wright.

## SIR HENRY DALE'S TRIBUTE

Sir Henry Dale said that he had an easy task before him, since all were present with the one object of expressing their admiration and affectionate regard for Sir Almroth Wright, now approaching the completion of his seventy-fifth year. They wished to tell him that they all realised what science and humanity had gained by his complete and tireless devotion, through so many years, to the increase of health-giving and life-saving knowledge, by work with his own skilful hands and his own ingenious mind. They wished to ask him to allow them to leave a permanent memorial of himself and his work in his own institute, so as to give some contact with his inspiring personality to those who would be working there long after all present had passed from the scene.

Some of those present could appreciate Almroth Wright's achievements chiefly from their practical results in the prevention and cure of disease and the relief of suffering. They would have in mind the comparison—who could miss it?—between the tragic toll taken of our armies in the South African War by the enteric fevers and the experience of the Great War, in which this one of the weapons in death's armoury had been effectively put out of action by the knowledge which Almroth Wright's researches had by then made ready for use. The great institute in which they were meeting was itself a monument of generous recognition of the great practical results for humanity, which had long been, were still being, and would continue to be obtained by the work in progress there into a far distant future.

There were others among those present who from a more intimate and expert knowledge could recognise not only the practical results, but the detailed interest and subtle beauty of the researches which had made these results possible. They knew their friend Sir Almroth Wright as a scientific philosopher, building and rebuilding, with brilliant ingenuity, the theories which gave order and coherence to the facts which he observed, and threatening to tax the resources of the Greek Lexicon for nomenclature to give precision to his ideas; but, though Wright was a philosopher with this scholarly instinct, it was never in the study or the library that they expected to find him. They knew by experience that, when they visited him in that institute, at any time of the day or even far into the night, they would find him bending over his laboratory bench, patiently at work with his own hands and eyes, and with the simplest of mechanical aids, putting ingenious questions to Nature, and loyally and humbly accept-

ing her answers. In that he resembled the other great scientific investigators throughout the ages. When he thought of their friend at his laboratory bench he was reminded of another great medical investigator—a friend of Sir Almroth Wright's—the late Paul Ehrlich. Ehrlich used to say that he could carry out all the experiments which he wished to make if he were provided with a supply of dyes and chemicals, a handful of test-tubes, a water-tap, and a sheaf of blotting-paper. It might be suggested that Almroth Wright would require for his beautiful researches little more than a supply of glass tubing, some rubber teats, a dab of plasticine, a gas burner, a microscope, and a tolerable incubator. With these he would need as material only some drops of blood, taken from himself, his colleagues, or his patients—for throughout his career, from his earliest researches to those which were still actively in progress, he had been consistently a man of blood. With these simple appliances and materials, his inspired imagination would devise experiments leading always to deeper knowledge of the nature of human blood, with its subtle mechanisms and delicate reactions to infection. He sometimes thought that they might regard Sir Almroth Wright as one of the born burglars of Nature's mysteries, fashioning his skeleton keys with his own ingenious fingers from the most homely materials, and using them with a touch of genius to force one after another of the intricate locks with which Nature seems to guard her secrets.

Seventy-five years was a long innings, and, in the case of Sir Almroth Wright, the score was 75 not out and well set. His long career included periods at Belfast, Dublin, Cambridge, Sydney, the Army Medical School at Netley, and, lastly, the Inoculation Department at St. Mary's Hospital, which he founded, and where they still found him working with a group of enthusiastic colleagues. In every place where he had been he had acquired devoted friends and admirers and enthusiastic disciples, and all were represented among the subscribers to the memorial, which they were going to ask him to accept, and many of them were represented in person in that gathering.

The portrait bust by Donald Gilbert, which was now unveiled, had the advantage over any painted portrait, that the subject could be seen from every aspect. It would preserve a memory of Sir Almroth Wright, which was the most familiar to those who visited him in his laboratory—namely, that of the back of a massive head and shoulders, bowed with patient diligence over his working bench. From the other aspect they would see no actual smile fixed in permanent bronze; but, he thought that they would agree, there was the hint and promise of the smile of friendly humour, which so characteristically lit up Sir Almroth Wright's features when he was talking to his friends. They all hoped that their friend would be willing to leave this portrait and memorial of himself in the niche on the landing of the institute, which the architect had, with proper foresight, provided for such a purpose.

He could not help introducing one note of sadness into a happy occasion. There was one man whom they were all sadly missing on that day—Almroth Wright's devoted friend and assistant, and his most intimate collaborator for many years, and, in more recent years, his own (Sir Henry Dale's) most loyal senior colleague and dearly loved friend, Stewart Ranken Douglas. All who knew Douglas, who died last

January, would know that he would have been among the most enthusiastic members of that gathering in honour of his great friend and teacher.

Sir Henry Dale then handed to Sir Almroth Wright an illuminated address, with the names of all the subscribers to the memorial bound in a small volume, asking him to receive this and the portrait bust as very sincere tokens of the admiration and affection in which he was held by all who had participated, and of their desire to keep the memorial of his personality and his influence alive among all who would follow him in his work.

#### SIR ALMROTH WRIGHT REPLIES

Sir Almroth Wright deplored that language provided only descriptive words for objects and events, and made no provision whatsoever for the more important business of expressing the emotions. Everybody was aware of that defect of language. The lover found it difficult to express his affection even to an ideally sympathetic audience of one. And everybody found it difficult to express in a convincing manner sympathy with the happiness or bereavement of others. And a man who had to express an internal commotion of gratitude experienced, as he did, the same sense of incompetence.

I would have you note that it is not impossible to express emotion through the channel of appropriate combinations of rhythmical words. It can be done provided only you are an orator and a poet. When however you are neither the one thing nor the other, then you have only the poor alternative—and I propose to avail myself of that now—of enumerating those to whom one feels one's special thanks are due.

I would, first in order, desire to express my gratitude to my friend Sir Henry Dale for having done me the honour of functioning as your spokesman and for having, in conveying this gift of yours to me, employed every sort of over-indulgent kindly expression. I would further express my gratitude to the sculptor—Mr. Donald Gilbert—for the skill and pains he has lavished upon this bust. I would express my thanks also to all those numerous friends whose names are written in this book as co-partners in this presentation. And I am specially grateful to the organising committee and their secretary, but I have from them the strictest orders that I must not even mention them by name. I would further thank all those who are assembled in this hall to-day for their courtesy in coming, some of them far away from London, to add distinction and grace to this ceremony. And lastly, I would thank those who would have desired to be here, but have been prevented by illness or absence abroad. And I have, among those absent for this latter reason, specially in mind Lord and Lady Iveagh. I would have you, when you presently make the round of the spacious quarters of this Institute of Research and Vaccine Therapy, bear in mind that this building owes its existence in large part to the munificence of Lord Iveagh.

I will now ask you to let me off saying anything more on the subject of my emotional reactions and my incompetence in giving voice to them. It will be more within my competence, and more congenial to the vocation of a scientist, for me to think out with you the philosophic basis of this ceremony in which Sir Henry Dale, and you, and I are playing our several parts. I would in particular very briefly discuss with you two questions: first, that of the association of the word pleasure with work in general and medical research work in particular; and,

secondly, the question of the rewards of work. The term "pleasure" is the most enigmatical in the English language. It embraces three kinds of "feelings" and "inward sensations" which are as far as far can be apart. First, pleasure includes what I am accustomed to call "voluptuary pleasures"—or, if you prefer the term, "pleasures of sense." All men, however much they may disagree in other points, are agreed that the pleasures of sense are genuine pleasures. There are pleasant sights and pleasant sounds and joys of taste and pleasures of smell—"fragrant the fertile earth," for example, "after soft showers." There is a *second* kind of internal sensations which count for a great deal in life, but to which the term "pleasure" is only doubtfully applicable. These are satisfactions of our sensory nerves—"satisfactions of our sensory requirements," we might call them. Sleep would be such a requirement. Life without sleep would be unendurable. And sleep has had from the poets its store of tenderest names. But even the poets would scruple to describe sleep as a pleasure. We may think further of the requirements of our nerves of temperature. We suffer from intense malaise when we are cold and chilly and we revive when we get comfortably warm. But relief from the malaise of chill is not what we have in view when we speak of pleasure. Precisely the same thing holds of freedom from hunger and thirst. There are many other somatic and psychological urges (biologists call these impulses *tropisms*) which are all of them reliefs from sensory discomforts, but would none of them properly be called pleasures. In particular, if I had time I might speak to you about our stereotyped cravings—our cravings for intimate contact with solid substances.

I come now to a *third* description of inward feelings which have been called pleasures. These are distinguished from the others by the fact that they come into consideration in connexion with work. And there are about these feelings all sorts of insulting misunderstandings abroad. I call it an insulting misunderstanding when a man who has never done a hard day's work in his life comes to one who has experience of the miseries of physical fatigue and tells him that it is perfectly plain that everyone who works works because he finds that work is a pleasure. Now no one who has ever done any strenuous physical or intellectual work ever thinks of work in that way. Hard work is always compelled work—there being of course two different sorts of compulsion. The one sort which we most frequently associate with the term is external compulsion. But there is also internal compulsion, this being an urge to get rid of the misery of wanting to do some particular thing (I call that misery "neuronic tension"), and to feel that the thing is done, or is at any rate so far as we are concerned done (I call that relief neuronic relief). And the proof that all hard work is done not for the sake of what is ordinarily called pleasure but from external or internal compulsion, is to be found in the fact that the "ordinary sensual man," who is untroubled by urges, absolutely refuses to undertake any of the serious forms of work. You cannot get him to dig the ground, or to learn languages, or to follow any handicraft or profession, and you may tell him as much as you please that there is pleasure in hard work, but he—for he is not a fool—knows perfectly well that there is in hard work always more pain than pleasure and more "neuronic tension" than "neuronic relief."

I have been talking with you, as you will have recognised, in quite general terms about the relation

between work and that spurious entity which is denoted by the term pleasure. But while most of you have been dwelling upon the instances of successful research work emphasised by Sir Henry Dale, all of us here who are engaged in *medical research* have had in mind the enormous disproportion of failure to success. And it is that which puts medical research in the same category of pleasure-giving occupations as, let us say, painfully attempting to climb Mount Everest, or passing a winter alone under the snow for the sake of making meteorological records.

I pass now to consider what are the external rewards of research work. For you will want to know whether the hard work of medical research can be made up to the worker by external rewards; and you will want to know something about the available rewards. I may remind you, to begin with, that Marcus Aurelius scoffs at the notion of rewards. "Does the eye," he says, "ask a reward for seeing, or do the legs ask a reward for walking?" And, you may rejoice, Does the brain ask a reward for thinking? That sort of high flown talk may seem foolishness, so I return to the discussion of rewards and of the appropriate sort of rewards for successful research.

I have it from the lips of a very famous research worker now dead that he who did important research work, such as he himself had done, should receive the emoluments of an archbishop and should be presented with a Rolls-Royce car and a salmon river. I have also heard from more than one research worker that those who are successful should be rewarded with titles of honour and public fame and decorations and fellowships of learned societies and gold medals and honorary degrees, and I can take heart of grace and say that to me these things may upon occasion have their value. For there is in my memory a speech made by a distinguished friend here present when returning thanks for a dinner given to him on his election into the Royal Society. He made this point, that every intellectual worker who is not incurably vain must in due season ask himself whether he is really the stout fellow that he imagines himself to be. And there followed then the point that a man who has been perturbed by such self-questionings is put into good heart again by his election into a learned society or the award of a medal, for these may be taken as sure indications that his work is really held in some esteem. I should like to put this to you; that the amount of pleasure that can be extracted from gratified intellectual vanity is—I venture to think—very strictly limited. And as for the ordinary flattering speech it is much better immediately forgotten. And there is with flattering speeches this special disadvantage—a man cannot with any decency go about retailing them to his friends. But I would make here one exception. There is a kind of flattering speech which is so tempered with reserves and criticism that it may quite profitably be remembered; and there is this good point about such a speech that it may without immodesty be repeated. Let me give you an example. A professor was seeking information as to the merits and demerits of your honourable servant now addressing you. "Oh!" replied Metchnikoff (and the professor reported this sally to me with pardonable pride), "Wright is a man who has very good original ideas; but he has also ideas which are only original."

I come now to the point as to what is the really gladdening reward of laborious research work. I find this reward not in the pleasures of sense which arrive in the course of our work. For these are few and rare. Nor do I find that reward in the neuronie relief which comes along with weariness at the end of a

long day's work, for the work of the day often turns out unprofitable. But I find that reward in the satisfaction of certain important psychological requirements. Just as a man requires sleep when he is tired, and food when he is hungry, and just as he longs for contact with the firm land and rest after a bad channel passage, so he requires, for the peace and satisfaction of his mind, some goodwill and affectionate esteem from those around him. Presentations, as I understand them, have something to do with this and this presentation which has been conveyed to me constitutes, I venture to believe, no exception to that rule. Finally, let me cite to you a passage that strikes the note upon which it will be good to end. It is—you will be surprised to hear—a criticism (I think a very penetrating criticism) of Shakespeare by Bernard Shaw. This is the passage:

"You suddenly see that Shakespeare, with all his flashes and divinations, never understood virtue and courage—never conceived how any man who was not a fool could, like Bunyan's hero, look back from the brink of the river of death over the strife and labor of his pilgrimage, and say, 'yet do I not repent me'; or, with the *panache* of a millionaire, bequeath 'my sword to him who shall succeed me in my pilgrimage, and my courage and skill to him that can get it.'"

## MEDICINE AND THE LAW

### Heart Disease as an Accident

*Reddish v. London, Midland and Scottish Railway*, decided at the Manchester county court last week, was one of those interesting cases where death from heart disease is found to be an accident within the Workmen's Compensation Act. An engine-driver collapsed and died on the express from Manchester to London. The court had to consider whether his employment had caused a strain which in turn had caused death. The widow contended that the heart attack was due to her husband's effort in helping to turn the turn-table at Manchester station before beginning the journey: it was aggravated, she said, by his action in closing the regulator of the engine when the train was running down from Haddon Tunnel to Rowsley. The judge went in person to the railway station, entered the cabin of an express engine, and tested for himself the requisite degree of exertion. He came to the conclusion that to pull the regulator over when the train was at rest meant no serious effort to an engine-driver in good health, but that, if the train was travelling down an incline with considerable oscillation, the effort would be a strain to a man in Reddish's state of health. The work contributed to, and materially accelerated, death; the employers were therefore liable to pay compensation.

The legal position has been well established since *Clover Clayton and Co. v. Hughes* in 1910, where the workman ruptured an aneurysm of the aorta while merely using a spanner to tighten a nut without any unusual effort. There was medical evidence that the aneurysm was so far advanced that death might have occurred during sleep. The employers contended that it was a case of disease and not of accident. "Accident," they argued, must be some sudden or unexpected occurrence of an untoward kind; the ordinary use of a spanner could not be an accident within the statute. The Lord Chancellor, however, laid down that the accident might be "something going wrong within the human frame, such as the straining of a muscle or the breaking of a blood-

vessel." It was sufficient that the "accident" was too great for the man undertaking the work, whatever the degree of exertion or the condition of health. It is unnecessary to prove sudden strain, but there must be evidence to connect the physical breakdown with the work. Thus in *McNamara v. Davis* (1933), where a lorry-driver was found dead beside his lorry and it appeared that he suffered from an aneurysm which had burst, the employers were held not liable in the absence of evidence that any accident had caused, or contributed to, his death. On the other hand, in two further cases decided in 1933 the employers had to pay. In *Partridge Jones and Paton v. James* the workman was a dipper in some iron-works; in *Falmouth Docks v. Treloar* he was a labourer unloading sacks of china clay. The arbitrator, said the court, must always consider whether, in substance and so far as he can judge, the accident comes from the disease alone (so that, whatever the man had been doing, the fatal result would probably have occurred all the same) or whether the employment contributed to it.

### Sardines Unfit for Human Food

A recent prosecution at the Mansion House disclosed some discreditable dealings in sardines unfit for human food. For some reason, which puzzled the presiding alderman, a consignment found unsatisfactory when examined at the London Docks last July was not condemned and destroyed forthwith at the time but was allowed to be sent back to the Portuguese packers. Some of the tins were found to be "blown" and to have been resoldered; the goods were far below the standard rightly required of food for human consumption in England. Last December this unwelcome consignment reappeared at the City and Continental Wharf, Upper Thames-street. Though it had been "reconditioned" and repacked in Portugal, it was none the more fit for human consumption. It was accordingly seized and condemned and the prosecution followed. The defendant, Edward Montague Fogden Humphrey, of Waverley Manor, Great North Way, Hendon, was summoned as the owner of the consignment. He pleaded "guilty." It was stated in extenuation that the goods were intended for re-export rather than for sale in England; there was indeed a half-suggestion that they were destined to be war stores for the Abyssinians. Evidence was given of a previous conviction for trafficking in dangerous drugs for which he was sentenced to six months' imprisonment in 1923. The alderman now imposed a sentence of three months in the second division. A representative of the *Consorcio Portugues de Conservas de Peixe* said that the president of that association had taken the trouble to come to London in case he could give the court any assistance. It was stated that the persons in Portugal instrumental in sending these sardines back to London after the first inquiry had been fined something like £1800 and forbidden to engage in the sardine trade for two years. It seems a pity that English law has no equivalent power of disqualifying a dealer who shows such indifference to proper standards of public health. Our rude forefathers might have put him in the stocks and fed him with his own unsavoury wares.

### Venereal Disease Act Infringement

The House of Commons lately showed no desire to prevent quacks from advertising their cures for cancer, epilepsy, and other afflictions. There is, however, one range of ailments for which Parliament has forbidden remedies to be prescribed or recom-

mended by anyone but a registered medical practitioner. The Venereal Disease Act of 1917 applies its prohibition even where the defendant has some genuine knowledge of pathology. On March 19th Ernest S. Lewis was fined £15, with £5 5s. costs, at Bow-street police-court, for having "announced" treatment for venereal disease in the pages of a book entitled "Every Man, Woman, and Child their Own Physician." The prosecution stated that it was probably true that Lewis had considerable knowledge of pathology. Lewis himself said that his book emphasised that the treatment which he advocated should be used in conjunction with medical supervision. He did not know he had committed any offence. The magistrate pointed out that the maximum punishment under the Act was two years' imprisonment; it was clear that the legislature intended serious notice to be taken of such offences.

## UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

### DAYTON DISPENSES WITH CLINICS

DAYTON, Ohio, is the headquarters of the National Cash Register and is a typical mid-western manufacturing city of 200,000 inhabitants. It is situated in Montgomery county. In March, 1934, the county medical society voted to close all out-patient clinics in the city. There had been some precedent for such action. The therapeutic clinics of the Los Angeles county health department had been abolished in the previous year. Youngstown, Ohio, had closed all clinics except those catering for patients with communicable disease. But Dayton is believed to be the first city to have made a complete sweep of all its clinics of whatever nature.

Organised medicine here is traditionally opposed to clinic practice and nourishes a belief that hospital and health department clinics habitually serve many patients who but for such service would consult and pay private practitioners. The advent of the depression lent fervour to this need as doctors saw many of their former paying patients added to the clinic rolls. From 1929 to 1933 the relief rolls of the city increased by 400 per cent. In the same period the attendance at public clinics increased by 160 per cent. Moreover when federal aid became available for the medical treatment of indigents, even the poorest became paying patients of a private physician when they did not elect to attend a clinic. Anyhow the clinics were closed. On Dec. 1st, 1935, federal aid for medical relief came to an end. The county relief funds also were depleted. On Dec. 2nd the Dayton health department reopened its venereal disease clinic staffed by two part-time salaried city physicians. The opening was approved by the clinic committee of the county medical society provided (1) there should be adequate investigation of the economic means of patients; (2) that the clinic be held on city owned property and that the doctors be adequately paid. The public relations committee is at present exploring the possibilities of opening other clinics to meet the present pressing need.

The debate as to the desirability of "socialised medicine" continues in American high schools, doctors in almost every community contributing to the negative. Common arguments against "socialised medicine" are that it destroys the physician-patient relationship, that it is unnecessary

since doctors already supply all needed medical care free of charge when the patient cannot pay, that it introduces politics into medicine with resulting political patronage and inefficiency. Exactly what constitutes "socialised medicine" it is not easy to say. Physicians are employed on a part-time basis in many communities to take care of the indigent sick, and this with the apparent consent if not approval of the local medical societies. The American Medical Association has for some years given publicity to an arrangement whereby several county medical societies in Iowa have contracted with the local government to supply medical service to indigents. Some of these Iowa contracts, but by no means all of them, guarantee choice of physician to the patient.

#### MAYHEM CHARGES IN CALIFORNIA

Two doctors in California have been indicted on charges of conspiracy to commit mayhem in connexion with the sterilisation of Ann Cooper Hewitt, only grandchild of the inventor of the quartz mercury vapour lamp. The California sterilisation law applies only to those legally committed to State institutions as insane or feeble-minded. Since no evidence was presented that Miss Hewitt had ever been so committed the judge ruled that the sterilisation law could not be invoked by the defence. Meanwhile the programme for eugenic sterilisation goes forward. The Human Betterment Foundation<sup>1</sup> reports that in the last year it has distributed more than 40,000 of its pamphlets in response to requests from 436 college instructors. Of these 431 are teaching in the United States and its territories and five abroad, in Canada, England, and Syria.

### VIENNA

(FROM OUR OWN CORRESPONDENT)

#### PSITTACOSIS IN CAGE-BIRDS

FIVE years ago, when there was an epidemic of psittacosis in Germany, quarantine was enforced upon all birds imported into Austria; the danger was then believed to be confined to parrakeets from South America. Occasional patients were suspected of having the disease, when they were known to have been in contact with parrakeets, but nothing could be proved and they all recovered. Prof. Eppinger, however, has recently had in his clinic a woman suffering from pneumonia of unusual type, the severity of which was out of all proportion to the mild symptoms. There was also a kind of "migration" of the pneumonic foci which aroused the professor's suspicions, as he had had the opportunity a few years before of observing 25 cases of psittacosis in the Rhineland. This patient had also kept two parrakeets. On the twelfth day specimens of blood and sputum sent to the Institute of Veterinary Infections were reported as giving positive reactions for psittacosis, and Prof. Gerlach, the director of the institute, succeeded for the first time in cultivating the virus from the blood and sputum. The patient had meanwhile recovered, though she was still in quarantine. The two birds had now died, but the authorities were able to exhume the bodies; both gave positive reactions for psittacosis. The shop was traced that had sold the parrakeets and orders were given for the destruction of its entire stock—176 birds in all, including 20 canaries, some forest

birds, and 2 birds of paradise—and for disinfection of the premises. The majority of these birds were found after thorough examination to be infected, and among them all the canaries.

This case was reported by Prof. Eppinger and Prof. Gerlach before the Gesellschaft der Aerzte in Vienna, and in the discussion it was pointed out that the bird-fancier's shop had been infected in spite of the quarantine restrictions. The only safe precaution was to keep birds that had been reared in the country and to avoid those that had been imported. The public should refrain from too intimate contact with any cage-birds and these should have a prompt examination at the first sign of illness. With these measures it should be easy to quell if not to prevent entirely an outbreak. All cage-birds seem liable to contract the disease; its onset is never spontaneous, for cross-infection can always be proved. Strict cleanliness is as important in these pets as in dogs and cats, to ensure their health and to prevent the spread of disease to their owners.

#### A MUSEUM OF ELECTROPATHOLOGY

In concentrating the medical institutes and laboratories within the buildings of the old General Hospital, two extensive wards of the former psychiatric departments have been converted into a museum for electropathology, where there is ample room for lectures and demonstrations. This collection of specimens, which owes its existence to the unceasing efforts of Prof. Stephen Jellinek, has hitherto been seriously handicapped by lack of space. The new institute contains a large amount of very interesting and instructive material on the physiology and pathology of the effects of electricity on living organisms. It is the only museum of its kind, and during its 35 years it has attracted a large number of visitors to Vienna, engineers as well as physicians. It contains many unique specimens, collected from all parts of the world, and the results of numerous scientific investigations which have been made in the institute—for example, methods for prevention of electrocution, the improvements in the safety of electric apparatus, the problem of markings after the discharge of a current. The museum will be concerned with the following subjects: the effects of lightning, protection against accidents, electricity in the army, in treatment, and in forensic medicine. Regular courses, chiefly for post-graduates, will be held in the museum by Prof. Jellinek.

### BUDAPEST

(FROM OUR OWN CORRESPONDENT)

#### THE LEX VENEREA

THE foundations of the Bill called the Lex Venerea have been laid during the past two years by a committee of the National Public Health Association under the presidency of Prof. Edward Neuber, ministerial commissioner for the prevention of venereal disease. Similar laws and their effects in other countries have been carefully studied and the Bill has been adapted from these to meet the special needs of Hungary. It makes treatment compulsory and provides for the discovery and treatment of all infected persons. The Minister of the Interior will be authorised to demand serological and other examinations, and the Bill contains an innovation, the "sanitary control," enforceable against women as well as men. Prostitution becomes illegal, brothels

<sup>1</sup> Suite 321, Pacific Southwest Building, Pasadena, California.

and similar institutions are to be abolished, and the police will be ordered to combat the activities of street-walkers. Anyone who exposes another to the risk of infection will be guilty of a misdemeanour and if infection takes place will be very severely punished. There are heavy penalties also for those who marry while still infected, and the law enforces a medical consultation—though not an examination—before every marriage. Physicians are obliged to give written as well as oral instructions to their patients and to report any who suspend or discontinue treatment. They must also notify any known source of infection. Advertisements and treatment through correspondence are forbidden. Steps are to be taken to instruct young people in the dangers of venereal diseases.

#### LONG LIFE

Nonagenarians have been called into consultation in an effort to discover the causes of longevity, and questionnaires have been sent by the Hungarian Statistical Bureau to all in the country over 90. These old people, of course, are the best authorities on the subject, and they have been asked to answer 63 questions about their heredity, environment, and mode of life. Some of these relate to the age, financial status, and health of their parents and grandparents, others to their own health, physique, diet, exercise, and sleep. The questions go into some detail about such subjects as the number of meals and whether these are meat or vegetarian; the partiality to tobacco or alcohol, and the nature and extent of indulgence; the length of sleep, time of rising, hours of work in the past and at present; and whether the surroundings are congenial. The part of the house in which the nonagenarians live is considered important, for four-fifths of the inhabitants of Budapest live in flats, most of which are five stories high. The conclusions of the Statistical Bureau will soon be published in the press for the benefit of the public.

After protracted negotiations and much expert advice the municipality here has made a contract with the Belgian firm Union Minière du Haut Katanga. Budapest will buy outright 1500 mg. of radium and hire 3242 mg. A cheaper offer had been made by an Austrian firm but it could only deliver the same amount in five monthly instalments and would not lend any; so its offer was declined.

The Budapest Health Resort Committee has received the grand prix given by the bureau of the World Exhibition held last summer in Brussels. It was awarded for the exhibit of modern bathing facilities and is much valued on account of the keen competition that there was from all parts of the world.

## IRELAND

(FROM OUR OWN CORRESPONDENT)

#### THE IRISH HOSPITALS SWEEPSTAKES

THE draw for the seventeenth of the Irish Hospitals Sweepstakes was held at the Mansion House, Dublin, last week. The total receipts from the sale of tickets was over £1,400,000, of which the share to be handed to the National Hospital Trustees will be approximately £467,500. The sum is an increase on that which was received at the sweepstake on the Cambridgeshire last November, but less than that at the sweepstake on the Grand National a year ago. The total sum which has been collected for hospitals in

the seventeen sweepstakes since November, 1930, is approximately nine and a quarter million pounds. It was announced at the draw that the Minister for Local Government and Public Health had now given his approval to the scheme for the endowment of medical research put before him by a representative body of those interested in medical science, and that only certain legal formalities had to be gone through before the first grant would be available. It is understood that the council to control the scheme, must be given legal status as a registered association before moneys can be granted to it by the Minister. It is expected that, as soon as registration is effected, a grant of some £10,000 will be immediately available.

#### PROVISION FOR CARE OF SANE EPILEPTICS AND MENTAL DEFECTIVES

The Irish division of the Royal Medico-Psychological Association is trying to impress the Minister for Local Government and Public Health with the need for provision of care and treatment for mental defectives and sane epileptics. At present many of these unfortunate classes are either in mental hospitals or in district hospitals, in neither of which can they get curative treatment or educational care. The joint committee of Grangegorman Mental Hospital has recently passed and circulated a resolution in support of the activities of the Medico-Psychological Association, adding its opinion that "the establishment of suitable institutions or centres for the care and treatment of these afflicted classes would result in a saving to the community by reducing the number of admissions to mental hospitals and prisons, whose inmates are to some extent recruited from these sources." The committee further asks that the co-operation of medical officers of health and of school teachers should be sought in order to collect information as to the mentally defective children throughout the country who would be capable of education and improvement under persons specially qualified to deal with such cases.

#### DR. JOHN MILLS

The death of Dr. John Mills, resident medical superintendent of Ballinasloe Asylum, occurred in Dublin recently after a long illness. Dr. Mills graduated from Dublin University as M.B., B.Ch., B.A.O. R.U.I. in 1890. After a short period as house surgeon in the National Eye and Ear Infirmary, Dublin, he decided to practise in lunacy and went as clinical assistant to the Richmond Asylum in Dublin, and thereafter devoted himself to the care of the insane. Almost his whole professional life was spent in Ballinasloe, first as assistant medical officer, and for some fifteen years past as medical superintendent. Ballinasloe is in an out-of-the-way part of the country, and asylum practice is often detached from other branches of medical practice. But Mills became one of the best known, most trusted, and most loved members of the profession in Ireland. He was active in every matter of medico-political interest. He was for many years a member of council of the British Medical Association and a member of the Irish Medical Committee. When, about 1912, the interests of the medical profession appeared to be threatened by the National Health Insurance Act, it fell to Mills's lot to organise the profession of the province of Connaught, and despite the pressure of his official duties, he found time to visit almost every medical man in two counties. He was one of the most active members of the Irish branch of the Medico-Psychological

## CORRESPONDENCE

## TREATMENT BY PROLONGED NARCOSIS

To the Editor of THE LANCET

SIR,—I have read with great interest the leading article on treatment by prolonged narcosis in your issue of March 21st, which has done a great deal to clarify the position with regard to the dangers and efficacy of the treatment. There are one or two points of considerable importance that have not yet been sufficiently stressed. As your article suggests,

“there is no precaution, no routine procedure in their administration (i.e., that of malariotherapy and prolonged narcosis) which can take the place of special experience in their use, or good clinical judgment in selecting cases and supervising the course of the therapy.”

and I believe that much of the present confusion is due to neglect of these fundamental precautions. The method, which at its best is a difficult one, requires expert supervision and keen powers of observation for the detection of early danger signs if fatalities are to be avoided, and to be of therapeutic value and free from risks it should never be undertaken by the wholly inexperienced.

In this connexion it is interesting to note Oberholzer's criticism of Müller's comprehensive review. He observes that amongst the 17 authors whose work Müller summarised there was only one (Stuermann) who had at his disposal a material of more than 50 cases, the others having published results on work which frequently embraced fewer than 20 cases. These workers were for the most part inexperienced in the management of prolonged narcosis, and their results as one might expect, showed a proportionally larger number of catastrophes and failures. This unfortunate tendency on the part of over-zealous psychiatrists has no doubt to some extent contributed to bringing the method into disrepute.

If a plea should be necessary for a form of therapy that has proved of undoubted value in many forms of mental disorder it would be not only for caution in applying the method, but also for caution against hasty condemnation, based on results in such series of cases. On the other hand, as you point out, the treatment can be carried out in the vast majority of cases without a hitch, if the physician has thoroughly familiarised himself with the method beforehand, and has realised that no routine procedure or set rules, but only the condition of the patient during treatment, must be his guide. As regards dosage it is impossible to generalise; each case must be treated according to its own particular requirements. Although the “mitigated” form of narcosis, where not more than 4 c.cm. somnifaine is used per diem, may be successful in many cases, it will be found that larger quantities (up to 6 c.cm.)

(Continued from previous page)

Association. He was a very progressive alienist, and indefatigable in his attention to the welfare and comfort of the sufferers committed to his care. To them and to their relatives he was more than a doctor, he was a friend in whom they trusted. His death is a grave loss to the poor of the counties of Galway and Roscommon, as well as his colleagues in the profession the good repute of which he did much to enhance.

are often required for the treatment to be efficacious. In the 107 cases reported by Muriel McCowan and myself the average dose in 24 hours more often than not exceeded 4 c.cm. in 24 hours. The dosage, however, varied so much from one individual to another that it was found impossible to lay down any definite rule. Again, most workers who have given insulin a serious trial as a protective against the toxic risks speak favourably of its effect in this direction. Thus several Scandinavian workers (Östlind, Gjessing, and others) encountered fewer complications with the use of insulin than without, whereas glucose alone made but little difference.

Whatever theories of narcotic action may be held there can be no two views about the benefit obtained by combating rationally the state of severe ketosis which arises during the course of prolonged narcosis.

I am, Sir, yours faithfully,

ROLF STRÖM-OLSEN.

Runwell Hospital, Essex, March 25th.

## THE NUTRITION QUESTION

To the Editor of THE LANCET

SIR,—The thanks of your readers are due to Dr. Hutchison for provoking a discussion on this subject in your columns. Its importance is so great that a statement of certain facts may be permissible even if I repeat something of what I said at a recent meeting of the Royal Society of Medicine (see THE LANCET, Feb. 1st, p. 258). As Dr. Hutchison points out, one of the difficulties is the lack of definition of terms that are frequently employed.

1. It is certain that on the average children of the well-to-do are for their age taller and weigh more than those of the poorer classes; in fact, the grade in society is indicated by the amount of growth, as appears from Elderton's figures. Public school boys are taller for their age now than they were 50 years ago. The evidence is in favour of these differences being due to the presence or absence of growth factors in the food, though heredity also plays a part.

2. When the average height is compared with the average weight this relation, which we look upon as the best measure of “general nutrition,” is the same for all classes. This applies to public school boys now and 50 years ago (Roberts), to elementary and other school-children in this country observed by Greenwood, Fleming and Martin, Elderton, and to children in America observed by Baldwin and by Benedict and Talbot, in Germany by Camerer, in Denmark by Bierring, and in Sweden by Nylin.

These two facts are well known, but perhaps their combination has not been sufficiently emphasised. Riches tend to produce giants, poverty to produce pigmies; both giants and pigmies are on the average equally well formed. The height/weight relation is an excellent measure of under or over-nutrition (Dr. Hutchison's terms) of the *individual*; but cannot be used to distinguish the classes of society. The problem remains whether it is a disadvantage to be short. Dr. Hutchison suggests that it may not be and it was Prof. A. E. Boycott<sup>1</sup> who wrote in the Osler Memorial volume “on the importance of being rather small,” applying this to man as well as to other organisms. On the other hand, Sir John Orr<sup>2</sup> has defined as the standard of health “a state of well-

<sup>1</sup> Contributions to Medical and Biological Research, New York, 1919, i., 226.

<sup>2</sup> Food, Health, and Income, London, 1936.

being such that no improvement can be effected by a change in the diet." On this definition, which many would agree with, poor children are not perfect in health though this does not mean that they are "starving or even suffering from such a degree of ill-health as is recognised in the term disease."

Clearly additional criteria are desirable, such as are given by dynamometer, equilibration tests, and hæmoglobin determinations now being investigated by Dr. H. E. Magee<sup>3</sup> at the Ministry of Health. Then there is the incidence in children of those diseases where nutrition plays a part, as dealt with by Orr. If we view the evidence so far obtained, we must surely admit that the health of poor children could probably be improved by adding certain substances to their diet. This would not mean that the diet of adults should be increased, as in all classes of society they tend to eat too much already; hence the diabetic and cardiovascular diseases that Dr. Hutchison and all of us deplore.

I am, Sir, yours faithfully,

London, W., March 27th.

E. P. POULTON.

To the Editor of THE LANCET

SIR,—Dr. Neustatter's experience, as recorded in his letter in THE LANCET of March 21st, is probably unique. Much as one deplores the existence of poverty—and, personally, I should like to see the State provide every man, woman, and child in this country with food and other bare necessities of life—it is not a fact that poverty, per se (other than actual starvation, which fortunately need not exist at the present day), is a cause of malnutrition, as gauged by Dr. Neustatter's standard—viz., under-weight, under-height, pallor, poor posture, baggy eyes, poor muscular tone, and prematurely senile appearance. He finds 70 out of 240 boys examined by him in the poor districts of the East End of London to be of such poor physique. I doubt if anyone else has met with similar experience. I have examined many thousands of children in similar districts of London and have not found any considerable number having the standard of unsuitable physique given by Dr. Neustatter. On the other hand one not infrequently meets with such poor physique among the pampered children of the well-to-do. I have only very recently, in the course of a medical inspection of school-children in the East End, seen two children whose fathers were unemployed, but each of them looked a picture of health. They were above the average weight and height, had rosy cheeks, and were healthy in every respect.

I am, Sir, yours faithfully,

Harley-street, W., March 24th.

W. M. FELDMAN.

To the Editor of THE LANCET

SIR,—As a public health officer, whose work is mainly concerned with infants and children the vast majority of whom must be termed normal, I feel bound to express my indebtedness to Dr. Hutchison for pointing out that nutrition may be regarded as the public health "stunt" of the moment, and for emphasising the dangers of over-nutrition, to which some of us in the public health service may have unwittingly exposed those children brought for our advice.

If we have erred in this way, it must be due to the fact that we followed too literally the advice given us by the physiologists and specialist workers in nutritional fields, and emphasised year after year

in the annual reports of the chief medical officer of the Ministry of Health. We have been insistent to parents on the importance of an adequate supply of milk (say) not less than one pint per day—Sherman advocates two pints for optimum calcium intake—and of a regular supply of the so-called protective foods, including eggs, green vegetables, and fruits. We also knew that sugar protected against starvation, but had been warned of the dangers of a high carbohydrate diet. We had read of such experiments as Corry Mann's, where the addition of a regular daily milk ration in addition to a good basic diet—better in itself than many children get in the usual way—caused a more rapid growth and increase of physical well-being than in the control groups, and drew our conclusions accordingly. If we had advocated sugar as a protective food, certainly our advice would have been cheaper to carry out; the stumbling block in an enormous number of homes to an increased intake of milk, &c., proved to be the cost, and the Government, giving recent recognition to this fact, introduced the milk scheme for school-children, and therefore some millions are now being supplied with one-third of a pint extra per diem. If, on the same principle, a scheme for the cheap supply of the other protective foods were introduced so that their consumption were enormously increased, to what unknown dangers, brought on by this possible over-nutrition, does Dr. Hutchison suggest our children would be exposed?

If the dangers of over-nutrition in this connexion are rather vague, those of under-nutrition are certainly much clearer. Sir John Orr takes three characteristic signs of malnutrition in children to be rickets, bad teeth, and anaemia, all of which are widespread in the lower income groups, and all of which are directly affected by diet. "It is most interesting," he writes, "to note that these diseases and stunted growth are attributable to lack of those dietary factors—viz., first-class protein minerals and vitamins which are the constituents of the diets shown to be deficient in the lower groups." The common respiratory disorders, and those arising in connexion with whooping-cough and measles, are also of much more serious import in the lower income groups than in the higher groups.

With regard to the question of physique, Dr. Hutchison suggests that the "smaller and more wiry type fits in better with the conditions of urban life and a machine age." Presumably also it is this smaller and more wiry type which is rejected as physically unfit for the Army to the extent of between 50 and 70 per cent. If it is true, however, that this type may fit in better with our present state of civilisation, then we should rightly deplore the fact that reports of school medical officers from all over the country for many years past have shown a consistently slow but steady increase in the average weights and heights of school-children at all ages. It is true that public school boys are still bigger and heavier than elementary school boys at corresponding ages, but, on the other hand, the elementary school boy is now up to the standard of the secondary school boy of a generation ago. Does this mean that those fitted for the "urban life and a machine age" are likely to become fewer in number?

Dr. Hutchison summarises the purport of his paper as a protest against the pessimistic view that defective nutrition is prevalent in this country and the optimism which believes it possible to bring about a great improvement in the public health by an alteration in the national diet. Some of us may

<sup>3</sup> Proc. Roy. Soc. Med., 1935, xxviii., 713.

find it difficult to acquiesce in this attitude after reading two of the most recent summaries, Sir John Orr's "Food, Health, and Income" and Sir Robert McCarrison's Cantor lectures.

I am, Sir, yours faithfully,

V. FREEMAN,

Assistant Medical Officer of Health Heston  
Hounslow, March 25th. and Isleworth.

### FOOD PRODUCTION

To the Editor of THE LANCET

SIR,—It is suggested in your summary (March 21st, p. 681) of Sir John Orr's survey of nutrition that there are now "greatly increased powers of producing food." What, if anything, has happened in recent years to enable farmers to produce much more food per acre at little extra cost to themselves or the public—except, perhaps, in the case of poor grasslands? In 1922 a leading authority on the subject, the late Sir Henry Rew, said: "Within the past thirty years not only have many agricultural stations and colleges been established, but many millions of public and private money have been spent in promoting agricultural education and research. The result of this expenditure cannot be said to be very apparent in the statistical records of output."

I am, Sir, yours faithfully,

Manor-fields, Putney, S.W., March 21st. B. DUNLOP.

### SCURVY IN THE ADULT

To the Editor of THE LANCET

SIR,—In your last issue (p. 710) Dr. Archer and Dr. Graham have indeed made good use of the case of scurvy which came under their care. There is no doubt that scurvy is rare in the voluntary hospitals of this country. On the other hand, it is not quite so rare in the local authority hospitals which deal almost exclusively with the sick poor. During the last four years I have seen at least half a dozen typical cases of scurvy of varying degrees of severity. I have no doubt that my colleagues in municipal and poor-law hospitals have had similar experiences. I find that the patients are mostly elderly people living alone on a small pittance.

I am, Sir, yours faithfully,

W. A. RAMSAY,

Medical Superintendent, Crumpsall Hospital,  
Manchester.  
March 30th.

### OXYGEN ADMINISTRATION

To the Editor of THE LANCET

SIR,—In the annotation on oxygen tents on p. 730 of your last issue you point out that A. L. Barach recommends a flow of 6–8 litres of oxygen per minute with a tent that is not very airtight. Dr. Poulton uses 2–3 litres per minute and makes his tent more airtight. One of the main advantages of the tent is that it allows this great reduction of oxygen. If we are going to use 6–8 litres per minute a simple open box-shaped face mask is all that is required. With this we find it is possible to maintain an alveolar oxygen pressure of 60 per cent. with a flow of 6 litres per minute if a single catheter is placed 3 in. in the nasal cavity. If 8 litres per minute is used the catheter need not be within the nasal cavity but just outside.

This box mask may be made from thin cardboard; its length is 6½ in., breadth 4¾ in., and depth 2½ in. Its long axis lies in the long axis of the face and the eyes look over the top which is closed except for the entry of the catheter. On the back of the mask there is a triangular opening, lined with lint, into which

fit comfortably the nose and mouth. The bottom of the mask is freely open to the air at a space of 12 sq. in. (4¾ by 2½). The capacity of the mask is about 1000 c.cm. and the patient breathes the mixture of oxygen and air from this cavity. A flap at the lower end of the front side could be raised when food is taken.

The apparatus is simple to make, very light and comfortable in use, and it does not get overheated.

I am, Sir, yours faithfully,

London, N.W., March 28th. J. ARGYLL CAMPBELL.

### SOCIETIES CHARITABLE AND UNCHARITABLE

To the Editor of THE LANCET

SIR,—In writing to thank you for the valuable article in your issue of March 14th under this title, may I point out a remarkable legal anomaly. Christian Scientist parents are liable to prosecution and punishment for fatalities caused by their wilful neglect to supply their children with such a treatment as antidiphtheritic serum, for example, the great value of which, when given in time, has been very generally recognised by the medical profession for some forty years. The so-called antivivisectionists, to be logical, should be Christian Scientists or its equivalent; for they cannot make systematic use of modern medical treatment without availing themselves of knowledge obtained through physiological, therapeutic, and bacteriological experiments on animals.

Yet it appears to be legal for antivivisectionists, with no medical qualifications, to spend tens of thousands of pounds yearly in trying to persuade parents to withhold illegally such treatments from their helpless children; largely by means of propaganda including the aid of "harrowing descriptions and illustrations . . . in many cases calculated to deceive the public," to use the words of the 1912 final report of the last Royal Commission, in reference to shops, of which the then Home Secretary in reply to a question in the House of Commons was reported in the *Times* of June 11th, 1912, to have said: "I regret that I have no power to prevent such displays."

Would it not, therefore, be of importance to obtain the present Home Secretary's opinion on the advisability of ending this anomalous state of affairs, which has now reached a scale that it is a menace to public health?

I am, Sir, yours faithfully,

London, March 25th.

LEONARD ROGERS.

### EPILEPSY AND ALLERGY

To the Editor of THE LANCET

SIR,—It seems necessary to take a wider view than that taken by Dr. Oriel and Drs. Costello and Fox to explain the coincidence of epilepsy and asthma or migraine. The allergic side appears to be but a part of the whole mechanism which is a chain of emotional, neurological, chemical, and other factors. The psychological is just as important as the allergic factor in the problem. I should like to illustrate this by the case of a man whom I have had under my care.

This patient when a boy lost his mother and, since his father had to travel abroad on business, was sent to a boarding-school. The head master of this school was a sadist of the worst order and flogged the boy every day. Under this treatment the patient started to develop major epileptic fits—there does not appear to be any

doubts as to the genuineness of the epilepsy—and these became so marked that the father was informed and removed him to another school. At this new school the epilepsy disappeared but was replaced by migraine. He suffered from this until puberty when the migraine was replaced by attacks of depression which occurred in the spring (when his mother died) and elation which occurred in the autumn. These attacks gradually increased in severity until he was unable to work more than six months in the year. He came under my care about a year ago and was treated by psychotherapy. Last autumn was the first time for fifteen years that he did not have an attack of elation, and this spring he has, so far, failed to have his usual depression. His environment has been unchanged so that no factor other than the treatment can be found to have caused the disappearance of his symptoms.

I have recently seen a boy aged 14 years who complained of asthma, minor and major epilepsy, and headaches (which lacked the symptoms of typical migraine). The epileptic attacks started when he was aged 6 years and sent to England to school while his parents stayed abroad. He was under the care of a master who used to hit him a great deal, and was very unhappy. The asthma started when his parents visited him and he was not allowed to leave with them. It was controlled by allergic factors also. I had no opportunity to treat this boy.

It seems possible to explain the relation of emotion to epilepsy and migraine by postulating that emotion is a point of cortical excitation which is limited by inhibition. If the excitation overcomes the inhibition it can spread over the cortex either as a slow wave, which is migraine, or as a sudden wave, which is epilepsy. Whether asthma is due to this wave of excitation penetrating the hypothalamic regions it is difficult to know. In manic-depression the excitation (emotion) is not allowed to sweep over the cortex but is isolated. The allergic factors such as occur in asthma apparently stimulate one of the links of the chain between the highest cortical units and the bronchial musculature. It is only by postulating some such mechanism as this that one can explain the relief of symptoms by such diverse means as psychotherapy, drugs (such as Luminal), and desensitisation.

I am, Sir, yours faithfully,

CLIFFORD ALLEN.

Harley-street, W., March 30th.

### CARCINOMA OF THE CERVIX IN NULLIPAROUS WOMEN

To the Editor of THE LANCET

SIR,—In that useful little book the "Early Diagnosis of Malignant Disease," by Donaldson, Cade, Harmer, Ward, and Edwards, recently published, reference is made to the early diagnosis of carcinoma of the cervix and it is stated (p. 24) that "carcinoma of the cervix is found solely in patients who have had at least one child." At the Marie Curie Hospital 115 cases of carcinoma of the cervix occurring in women who have never been pregnant have been treated. In some of these, unfortunately, only temporary palliation was possible because the general practitioner, believing that carcinoma of the cervix never occurred in nulliparæ, had treated them for some months with douches, &c., before sending them to hospital.

I am, Sir, yours faithfully,

E. HURDON,

Director, Marie Curie Hospital.

Fitzjohn's-avenue, N.W., March 20th.

### A QUESTION OF PROFESSIONAL CONFIDENCE

To the Editor of THE LANCET

SIR.—Surely this is a very simple matter! Dr. A was quite right in conveying the information to his patient of her maid's complaint. Also, there is no reason why he should refrain from scrutinising the case sheet in the hospital. But if he took care to intimate to the mistress that a more tactful dismissal would be better, he would have saved a lot of trouble. The whole situation seems to have arisen, not through any breach of professional etiquette on either the doctor's or the hospital's part, but merely through a lack of a little of the tact and savoir-faire of which every general practitioner of repute is, or should be, possessed.

I am, Sir, yours faithfully,

March 30th.

M.R.C.S.

### FOTHERGILL TESTIMONIAL FUND

THE following is the fourth list of subscriptions to the testimonial to Dr. E. Rowland Fothergill received in response to the letter published in the *British Medical Journal* and *The Lancet* of Jan. 18th:—

Amount previously acknowledged, £967 8s. 6d.  
 Herefordshire Local Medical and Panel Committee, £15 15s.; Hull Local Medical and Panel Committee, £5 5s.; Sir John Atkins (London), £5; F. J. Gomez (South Petherton) and S. Hunt (Spondon, Derby), each £1 1s.; Dorset Local Medical and Panel Committee, £10 10s.; A. E. Hodder (Stafford), £2; Staffordshire Panel Committee, £20; C. Frier (Grantham), £2 2s.; Renfrewshire Panel Committee, £3 3s.; F. A. Roper (Exeter), £2 2s.; E. A. Gregg (London), £1 1s.; Burnley Panel Committee, £5 5s.; Lancashire and Cheshire Branch, B.M.A., £10 10s.; G. W. Beresford (Hove) and S. Fraser (Hove), each £1 1s.; Cleveland Division B.M.A., £5 5s.; Edinburgh Panel Committee, £2; Anonymous, 10s.; East Lothian Panel Committee, £2 2s.; Members and Staff of Brighton Insurance Committee, £5 5s.; Hastings Local Medical and Panel Committee, £21; A. E. Larking (Beckley), £1 1s.; Burnley Division B.M.A., £5 5s.; J. Livingstone (London (Hamilton)), £2 2s.; Manchester Local Medical and Panel Committee, £10 10s.; N. Kemp (York), £1 1s.; Blyth Division B.M.A., £3 3s.; E. D. Broster (Wirksworth), 10s. 6d.; Lanarkshire Panel Committee and Hertfordshire Local Medical and Panel Committee, each £10 10s.; J. M. Martin (Cheltenham), £1 1s.; L. A. Johnson (York), £1; Leeds Panel Committee, Nottingham Panel Committee, and Bournemouth Panel Committee, each £5 5s.; Barrow Panel Committee, £2 2s.; Cheshire Local Medical and Panel Committee, £50; Greenock Local Medical and Panel Committee, £5 5s.; Huddersfield Local Medical and Panel Committee, £2 2s.; North Riding of Yorkshire Panel Committee, £15; Morpeth Division B.M.A., £3 10s.; Surrey Local Medical and Panel Committee, £3 3s.; M. Du Bois Ferguson (York) and C. Charnock Smith (Hastings), each £1 1s.; Walsall Local Medical and Panel Committee, £3 3s.; Birmingham Panel Committee, £26 5s. Total, £1361 12s.

Cheques should be made payable to the Fothergill Testimonial Fund, and addressed to the Treasurer, Fothergill Testimonial Fund, British Medical Association, B.M.A. House, Tavistock-square, London, W.C. 1.

ROYAL NORTHERN HOSPITAL.—At the annual council of governors of the Royal Northern Group of Hospitals held on March 26th it was stated that the new section to St. David's wing had brought the bed complement of the Group up to 480, but unfortunately 43 of the beds were closed through lack of funds. The number of in-patients treated last year was 6295, and the out-patient attendances numbered 360,637. The casualty department, which is the Islington war memorial, received 18,956 patients, and the X ray department had 18,614 attendances, an increase of over 3000 on 1934. The expenditure amounted to £122,495, an increase of £6212, and the general debt of the hospital now stands at £139,460. An appeal for £350,000 will be launched next year, of which £138,000 will be devoted to maintenance and £212,000 towards buildings. The Zachary Merton trust has also offered £20,000 to provide a new section for early convalescent cases at Grovelands, Southgate.

## OBITUARY

**SIR ARCHIBALD EDWARD GARROD,  
K.C.M.G., M.D., F.R.S.**

CONSULTING PHYSICIAN, ST. BARTHOLOMEW'S HOSPITAL; LATE  
REGIUS PROFESSOR OF MEDICINE, UNIVERSITY OF OXFORD

THE death occurred at his house in Cambridge on March 28th of Sir Archibald Garrod, a leading figure for the last 40 years in scientific research and clinical medicine. We owe to Dr. Hugh Thursfield, his friend and colleague, the following sketch of his career and fine tribute to his great qualities.

Sir Archibald Garrod, the distinguished son of a distinguished father—Sir Alfred Garrod—has passed away in his eightieth year, and the medical profession has to mourn the loss of one who was not only a pioneer in a somewhat obscure field of research but was a source of inspiration and an example of accurate and clear-cut thought to many generations of medical students. He was born, so to speak, in the profession, and married into it, for his wife was the eldest daughter of Sir Thomas Smith, in his day the best-loved surgeon in London.

Marlborough and The House at Oxford preceded Garrod's entry to the medical school at St. Bartholomew's Hospital, where after holding the usual house appointments he became successively a teacher in the school, a tutor and registrar, and assistant physician on the staff. For this appointment, the immediate goal of his ambition, he had to wait more years than usually fall to the lot of the aspirant, for at that epoch St. Bartholomew's had a galaxy of medical talent, most of the members of which had reached the staff at an early age, and so blocked the path of Garrod and his contemporaries to promotion. It was therefore only after years of preparation that he attained his ambition. These years were busily employed in the day-to-day work of a medical school teacher, and in research work, which was mainly devoted to chemical investigations of the colouring matters, normal and abnormal, of the urine, a subject, which as he once said to the present writer, "lay on the very fringe of knowledge." His work in this field led to an appreciation of his merits, which at that time was probably higher on the continent, and especially in Germany, than at home, where outside St. Bartholomew's, and a small ring of scientific researchers, he was comparatively unknown.

It was during these years of waiting in connexion with St. Bartholomew's that he became attached to the staff of the Hospital for Sick Children, Great Ormond-street, in the work of which for the next twenty years he took the keenest pleasure. There

also came a period of waiting before he became a physician in charge of beds, but in later years he used to regret occasionally the loss of the opportunity of out-patient work, which with all its limitations and irritations, still offers an unequalled training to the clinician. Thus it happened that he was already past middle age before his reputation had spread beyond the walls of the two hospitals he served with so deep a loyalty and devotion. But he then began to enter upon a practice as a valued consultant, which though it never attained the extent of those of a good many of his contemporaries, yet made a demand on his time, owing to his cautious and deliberate accuracy. This involved to some degree the sacrifice of many of the researches he had planned. But though he

had thus to relinquish some of his personal activity in these directions, the spirit of research lived in him strongly, and in the years which were to come made him a source of inspiration to many of his younger colleagues and pupils.

The war found him with an established reputation and a grown-up family, only the youngest son being still at school. After serving the first part of the war in England he was appointed consulting physician to the Forces in Malta, where in busy work with a happy band of medical and surgical colleagues and helpers he spent the remaining years of the war. But the war brought him the greatest sorrow of his life. His second son was killed in action in the first year; his eldest

(Photograph by Lafayette)

SIR ARCHIBALD GARROD

son, who had become a doctor, was killed by a shell when working with an ambulance; and his youngest son who had survived a year or more of active service died in Cologne after the Armistice in the plague of influenzal pneumonia which in 1918 and 1919 attacked the Army. These repeated blows deprived him temporarily of energy and resolution, and it was a shadow of his former self which returned to St. Bartholomew's in 1919. However not long afterwards he was asked to take charge of the newly formed medical unit at that school, when he threw himself with reawakened zest and earnestness into work with the scope and aim of which he was thoroughly in sympathy. In the comparatively short time during which he remained director of the unit he was able to draw out the lines of an experiment which in the hands of himself and his successor, Prof. Fraser, has proved entirely successful.

From this post he accepted the succession to the professorship of medicine at Oxford, rendered vacant by the death of Osler. He did so with a characteristic modesty, declaring both in public and still more

emphatically in private that he could think of the names of several men better fitted than himself. At the same time he could feel that the work which he had been called to do in the unit at St. Bartholomew's was fairly started, and all his inclination was now to leave its development to younger men, and himself to embark on the "great adventure" of attempting to follow his admired and admiring friend, Osler. He could not, as he said, hope to emulate Osler's influence, and was wont, after he had been a short time at Oxford, to assert that in such a post every man must work on the lines which appeared to him to be most productive of good, and that no one should, or indeed could, pursue, in other than the broadest sense, the precise direction of his predecessor.

Others can appreciate the successes and the failures of his tenure of the professorship which he held till 1927, when on reaching 70 years of age he retired. He had in the meanwhile served both his own and all other English universities well on the Universities Commission.

In the meantime his only remaining child Miss Dorothy Garrod had maintained the family tradition of distinction, though in a new field, that of archaeological and anthropological research. Sir Archibald—he had been created K.C.M.G. in 1918—and Lady Garrod after leaving Oxford had retired to a house which they had long possessed in Suffolk, but not long afterwards they removed to Cambridge, where their daughter was now, in the intervals of her fruitful explorations in Gibraltar and the Near East, a director of studies at Newnham. Sir Archibald was received with open arms both by the University and Colleges of Cambridge; almost, he said, as if they had supposed him capable of changing Dryden's famous lines:

*Cambridge to him a dearer name shall be  
Than his own mother-university,  
Thebes did his green unknowing youth engage,  
He turns to Athens in his riper age.*

In this honoured retirement Garrod passed the remaining years of a life which in many respects was singularly happy, cheered by the warmth of his many friendships, clouded only lately by a steadily failing vision; retaining all his old interests, especially in medical and chemical research, and in his own chosen field still an acknowledged master.

Sir Archibald was, in the prime of life when I first knew him, of markedly handsome presence, with a finely shaped head and face, from which looked out dark eyes of an impressive brilliance, which at first sight seemed to promise quickness, vivacity, and perhaps irascibility. Yet with deeper knowledge it became clear that any such supposition was completely incorrect. Of irascibility there was never a trace; even by a momentary irritation he was but rarely overtaken, and never possessed but for a second or two; and quickness of wit, of which he had plenty, was always subdued to a somewhat slow and deliberate utterance, the outcome no doubt of his life-long habit of conscious self-criticism. This characteristic marked also all his teaching and writing, so that the bulk of his written work is comparatively small, but, especially in his volume on the "Inborn Errors of Metabolism," holding "great riches in a little room."

To all those who have enjoyed the privilege of working with Sir Archibald at any period of his active life, but most of all in what were perhaps his two happiest periods, before the war and when director of St. Bartholomew's unit, his death will come as a reminder of a time when his interest and

enthusiastic desire to help were a part of their own best and busiest days.

Prof. Francis Fraser writes: "The death of Garrod leaves a gap in the medical profession that cannot be filled. There was no one quite like him. An able, practical physician when the need arose, patients, as he said himself, did not really interest him, and the complex problem presented by an individual who is ill did not really appeal to him for solution. In a patient he saw one symptom only, one abnormality, and on this he would concentrate, thinking about it, reading about it, and experimenting with it, all else ignored. It is the mind of the true scientist and often one wondered, and he wondered also, how he had come to be a practising physician. He was almost an onlooker when he applied himself to the daily task of seeing patients and treating them. This daily task was something that had to be done, a price that had to be paid, for the privilege of contact with the numerous intriguing puzzles that he found and set himself to solve. Often he would spend all morning at a window in the ward testing a urine that presented an unusual colour or smell. The morning's round could be left to others. If he could not find the answer himself he would consult Dr. Hurtley in the chemistry department or seek help from his friends at Oxford or Cambridge.

"Each group of students was to him the raw material in which he hoped to find an individual who would be interested in the search for truth, who would be inspired to see a 'higher medicine' in the problems of the ward, who would perhaps be tempted to ignore the immediately practical and devote his life to 'things that matter.' He would look back on his career as a teacher of undergraduates and pick out those whom he thought he had influenced to think clearly and honestly, and with pride he would name those whose careers he had guided. With these ideals and with these objectives in his teaching, it is no wonder that he welcomed the opportunity of becoming director of the professorial unit at St. Bartholomew's Hospital at the close of the war. In the war he had lost his three sons, and it was with paternal devotion that he moulded the unit and with paternal ambition that he looked forward to the unit giving the stimulus and the opportunities for the advance of clinical science to the next generation of medical men. It was only after careful thought and some misgivings that he left St. Bartholomew's Hospital in 1920 to succeed Osler at Oxford, and it was partly the hope that there he could sow seed on soil uncontaminated by considerations of careers and of utility that persuaded him to leave the unit so soon after its inception.

"At Oxford he found the administration of the medical faculty gave him the opportunities for advancing his plans for 'better medicine,' and it was there that he worked at 'Inborn Errors of Metabolism' and 'The Inborn Factors of Disease.' These books epitomise his medical outlook. He saw that there are problems in medicine that are the field of the clinician and that only the clinician can solve, problems that do not interest the physiologist or the pathologist, but require for their solution the aid of the pathologist, the physiologist, and the chemist. He stoutly maintained that the clinician must have his own laboratories, for only he saw the problems and only he would worry at them and solve them. Garrod's researches were biological, though conceived at the bedside, and few physicians have had the power to eliminate the sociological and

environmental factors that obscure clinical medicine and see the clear biological problems beneath as he did. His critical faculties never sterilised his intellect, his honesty was constructive.

"Inclined to long silences, with bushy eyebrows and gentle voice, he had a personality that claimed attention. What he said was worth listening to and worth thinking about long afterwards, for what Garrod said and what he wrote was always carefully pondered and examined. He could be sarcastic but was never unkind, so when he censured strongly there was good reason for it. The deaths of his sons in the war were blows that affected greatly his private life, and no one can tell how they influenced his work, but he was a scholar in all he said and gentle in all he did, and those who had the privilege of knowing him, lived better and worked better because of him."

There should be added to these tributes certain details in Garrod's professional career. It is true that the bulk of his written work was not large but he had a great gift for summarising, in the form of public addresses, both the bearing of his own researches and the influence upon scientific progress derived from other predecessors and contemporaries. At the Royal College of Physicians of London he delivered the Bradshaw lectures in 1900, taking as his subject urinary pigments in their pathological aspects; he was Croonian lecturer of the College in 1908, his subject being the inborn errors of metabolism, a theme developed in his book with that title, and also in "Inborn Factors of Disease" published in 1931. Lastly, as Harveian orator at the College in 1924 he set out in an eloquent way the debt of science to medicine. All these addresses were published in full in THE LANCET at the time of their delivery, and those who consult them will derive from them both wisdom and pleasure. In 1912 he was Lettsomian lecturer at the Medical Society of London. Here in four lectures he told the story of glycosuria with a wealth of detail, chemical and clinical, while the carefully compiled bibliography displayed erudition and industry. In 1920 he delivered the Schorstein lecture at the London Hospital on the diagnosis of diseases of the pancreas, and in 1923 the Linacre lecture at Cambridge, when he modestly entitled his accomplished delivery as Glimpses of the Higher Medicine. In 1927 he delivered the Huxley lecture at Charing Cross Hospital, taking for his subject the broad theme of diathesis. These various addresses amount to a considerable literary performance and many would like to see them published as a volume. To the *Transactions* of the old Medical and Chirurgical Society, to the *Journal of Pathology*, and to the *Proceedings* of the Royal Society he was also a valuable contributor.

He was elected F.R.S. in 1910 for his work in connexion with errors of metabolism, urinary pigments, and alkaptonuria, and served on the council of the society during 1914-15. He was for some time a member of the Medical Research Council, was an honorary member of many English and foreign foundations, and a member of the advisory committee appointed in 1924 by the Home Secretary to report on the administration of the Cruelty to Animals Act. His services as an examiner in medicine were requisitioned by the Universities of Oxford, Cambridge, Glasgow, Manchester, and Liverpool, and by the English Conjoint Board. He was given an honorary doctorate degree of the Universities of Glasgow, Aberdeen, Malta, Dublin, and Padua, the last distinction giving him particular pleasure as emanating from Harvey's university.

Garrod's claim to admiration and respect is unchallengeable, and regret for his death will be widespread and real.

### SIR JAMES SMITH WHITAKER, M.R.C.S. Eng.

LATE SENIOR MEDICAL OFFICER, MINISTRY OF HEALTH

WE announced last week the death at Farncombe of Sir James Smith Whitaker, the medical politician to whose organising powers was due much of the shape which the medical side of the National Insurance Act assumed.

James Smith Whitaker was a Yorkshire man, born in 1866 the son of John Whitaker, of Hawes, and was educated at Manchester Grammar School and Owens College. He qualified as L.R.C.P. Lond., M.R.C.S. Eng. in

1891 and was for a time medical officer in Wye House Asylum, Buxton. He then went into practice in Great Yarmouth and during his ten years in the busy Norfolk town became deeply interested from personal experience in many sides of the general practitioner's life. At that time it had become evident to all who took interest in the practice of their profession that doctors, especially in provincial towns,

suffered seriously from the methods of medical clubs. Numerous societies having as their professed objects life assurance arrangements added to their projects medical aid as an inducement to the public to enter their fold. Many of these societies were at bottom nothing but attempts to secure for the public medical attendance at low rates. And where the management of the society remained entirely in lay hands the interests of both medical men and public suffered badly, competent practitioners saw their poorer, and by no means always their poorer patients taken from them and handed over to the ill-paid salaried servants of a society. In Great Yarmouth an active association of this kind was in existence and its operations led Smith Whitaker to consider whether the medical profession could not organise resistance to a movement which was becoming increasingly mischievous to medicine and public alike. He was a local official of the British Medical Association but found that body not to be inspired with what he considered the necessary zeal or the adequate machinery to deal with the scandal. He associated himself with others who held the same view or who for various reasons were disappointed in the policy of the Association, and he became their spokesman at a meeting held in Manchester in 1900. The meeting in Manchester had for its object to consider the need for reorganisation of the Association, especially on the medico-political side, and the reformers were able at an important conference to take such a strong line that the existing authorities of the Association found themselves in sight of a

[Photograph by Elliott & Fry

SIR JAMES WHITAKER

serious break away from their body. The result, however, proved entirely different. A committee, upon which Whitaker sat, was appointed to enter into negotiations with the council of the Association, with the result that not only was the medico-political side of the Association reconstructed, but what was in effect a completely new constitution was introduced, under which the affairs of the Association have since been administered. In the revolution Victor Horsley took the lead, but Whitaker gave effect, through his remarkable ability for draughtsmanship, both to Horsley's principles and his own views. Under reconstruction the Association became a representative body, and Whitaker, who was appointed medical secretary, proved a conspicuous success in the post. He was a tireless worker, a good public speaker, and while always logical in his expositions, combined persuasiveness with severity, and as a tactician he was remarkably subtle.

On the introduction of the first Insurance Bill all these qualities were of the first advantage to the Association and to the medical profession, and the value that they would have to the Government in the many difficulties obviously ahead was recognised by Mr. Lloyd George who made the dramatic move of securing Whitaker's services for the National Health Commission. As for sound reasons the medical profession had just cause to be critical of the details for working contract practice under the National Health Insurance Acts, the acceptance by Whitaker of the post of deputy chairman of the Insurance Commission came as a shock to many—it wore the appearance of a desertion. But Whitaker was a strong man. He knew perfectly well that he would be reproached for going over to the side against which he had been in action, but he knew intimately the evils to which the new legislation was designed to put an end. He knew also how sound were the grounds on which the medical profession resented the Bill in its original shape, and he apprehended with courage and shrewdness that, while obeying what he considered a public call, he could serve the interests of the profession best by directing official attention to the existent evils. It was on those grounds, and with the formal approval of the council of the British Medical Association, that he accepted Mr. Lloyd George's offer. The result was that the medical profession found inside the precincts of the Ministry of Health a well informed and valuable friend.

The war broke out shortly after Smith Whitaker's appointment as vice-chairman of the Insurance Commission and he played an important part in many of the activities set in motion. At the conclusion of hostilities he settled down to his official duties and was an assiduous public servant in a position which gave no appropriate openings for his talents. It seemed as though the recollection of past abuses, which he had been prominently keen in abating, remained always with him; he was a legalist and formalist, and a champion of the practitioner's rights, but he never showed a large conception of the needs of public health. But the good work that he did for medical practice will never be forgotten. He was knighted in 1931, shortly before his retirement from his official post.

#### THE LATE MR. A. R. TWEEDIE

Two of the late Mr. Tweedie's colleagues have sent addenda to the obituary notice which appeared last week. One colleague writes: "I was associated with Tweedie in various ways and at various times during the past 40 years. He was a man of outstand-

ing ability, among his chief characteristics being his unbounded and untiring energy; and his readiness at all times to assist whenever his advice and help might be sought. It is said that he never sat in an easy chair to read the newspaper or a novel; his time when he was not engaged in carrying out the multifarious duties of his practice being occupied in contributing to the literature of his specialty, in translating, or in reading current medical literature. His aid was never sought in vain; he would throw his whole interest and energy into the elucidation of a correct diagnosis, and this having been made, all his time and thought would be given to affording relief. He was an excellent surgeon, and to his work devoted a whole-hearted enthusiasm; any young men interested in aural surgery found in him a very real friend and helper. His favourite phrase, 'Anything I can do to help, you have only to command me,' conveys the character of the man. He was possessed of a very genial humour, and was an excellent story-teller, and played all his games with the energy that he put into his work."

Another colleague writes: "Tweedie possessed an abounding generosity. He was the most loyal of friends and colleagues. Since the war he kept in touch with all the members of his unit, ever ready to help anyone who was in trouble. A lover of nature; of hills and moors and wild places; of the spring notes of the curlew and the golden plover. His capacity for work was tremendous, but his modesty was such, that in all his labours for the Deaf and Dumb Institute he never let his name appear. A strong man; a robust personality; a good speaker with a ready wit. A man of intense sincerity with a fierce hatred of anything that savoured of selfishness or pretence."

#### INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 21ST, 1936

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2453; diphtheria, 1215; enteric fever, 24; pneumonia (primary or influenzal), 1232; puerperal fever, 44; puerperal pyrexia, 116; cerebrospinal fever, 27; acute poliomyelitis, 3; acute polio-encephalitis, 1; encephalitis lethargica, 8; dysentery, 49; ophthalmia neonatorum, 83. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on March 27th was 6493, which included:—Scarlet fever, 1031; diphtheria, 1111; measles, 2927; whooping-cough, 724; puerperal fever, 17 mothers (plus 12 babies); encephalitis lethargica, 283; poliomyelitis, 5. At St. Margaret's Hospital there were 19 babies (plus 11 mothers) with ophthalmia neonatorum.

*Deaths.*—In 121 great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 114 (38) from measles, 4 (1) from scarlet fever, 32 (6) from whooping-cough, 24 (3) from diphtheria, 61 (22) from diarrhoea and enteritis under two years and 86 (19) from influenza. The figures in parentheses are those for London itself.

The mortality from measles has again risen slightly, the figures for the last seven weeks (working backwards) being 114, 105, 84, 88, 78, 58, 34 for the country as a whole, and 62, 58, 47, 38, 18, 14, 13 for Greater London. Manchester reported 8 deaths, Liverpool 7, Salford 5, Leyton, Tottenham, and York each 4, Dagenham, Bradford, and Leeds each 3, no other great town more than 2. Deaths from influenza were scattered over 49 great towns, Liverpool reporting 4, Portsmouth, Birmingham, and Cambridge each 3. Birmingham reported 6 deaths from whooping-cough, Liverpool and Manchester each 3. Deaths from diphtheria were reported from 15 great towns, 3 from Wakefield, West Ham and Liverpool each reported a death from enteric fever.

The number of stillbirths notified during the week was 294 (corresponding to a rate of 43 per 1000 total births), including 49 in London.

## PARLIAMENTARY INTELLIGENCE

### NOTES ON CURRENT TOPICS

#### Advertisement of Medicines and Surgical Appliances

THE Medicines and Surgical Appliances (Advertisement) Bill was the outcome of the labours of a committee representative of the various interests connected with the trade in proprietary medicines. Their work had been directed towards removing some of the worse abuses in the advertising of proprietary medicines, surgical appliances, and curative treatment. The advertisements which the Bill was designed to control are those which are not only grossly misleading to the public but also tend to bring legitimate proprietary medicines into disrepute. All the principal interests concerned in the proprietary medicine trade had taken part in framing the draft—the manufacturers, the distributors, and the advertisers—and the position of the unqualified practitioners of medicine had received the fullest consideration. The deputation which presented the Bill to the Minister of Health in July, 1935, included representatives of the following organisations:

Advertising Association.	Parliamentary Medical Com- mittee.
Association of Municipal Cor- porations.	Pharmaceutical Society of Great Britain.
British Medical Association.	Periodical Trade Press and Weekly Newspaper Propri- etors Association, Ltd.
County Councils Association.	Proprietary Association of Great Britain.
Institute of Incorporated Practitioners in Advertising.	Surgical Instrument Manu- facturers Association.
National Association of Insur- ance Committees.	Wholesale Druggists Sundries and Proprietaries Associa- tion.
National Pharmaceutical Union.	Wholesale Drug Trade Asso- ciation.
Newspaper Society.	
Parliamentary Committee on Food and Health.	

The Bill was presented by Mr. A. Duckworth in the House of Commons on Feb. 7th and a summary of its provisions appeared in THE LANCET of Feb. 15th (p. 400).

#### MOTION FOR SECOND READING

In the House of Commons on March 27th Mr. DUCKWORTH moved the second reading of the Bill. The scope of the measure was, he said, extremely limited. Its provisions had received the support and approval of a large number of bodies, including the representatives of the proprietary medicines trade, the Advertising Association, the County Council's Association, the Pharmaceutical Society, and many other bodies. It was not promoted by any vested interest and it was not intended to discriminate in any way between the qualified and the unqualified practitioner, nor did they believe that it could possibly damage the interests of any religious body or association since such bodies were specifically excluded from the provisions of the Bill. The Bill sought to remove some of the worst abuses that existed in connexion with the advertisement and sale of patent medicines and secret remedies. It also struck at another method which was only, he thought, practised by the unscrupulous person, and that was the method of offering to diagnose and give treatment by correspondence. The existence of the abuses against which the Bill aimed was not, he thought, disputed, and he did not think that anyone would seek to justify those abuses. The Bill was designed solely to give the public some protection against the worst of the forms of exploitation that were practised by fraudulent and unscrupulous persons for their own profit; and even should this Bill become law it would still leave open an enormous field for the activities of the swindler and the cheap-jack. When they considered the state of the law in this country as compared with the protection in this respect given by the law of other countries, particularly in the British Dominions, it might be justly argued against the Bill that it erred on the side of moderation.

The extent and widespread nature of the abuses which were aimed at by this Bill were first made known to the public through the report of the Select Committee of the House of Commons which sat from 1912 to 1914 and reported in August of the latter year. That Committee in their report made some startling revelations as to the fraudulent claims put forward in advertising many well-known patent medicines on the market and as to the ingredients used in their composition. The report laid emphasis on the abuses and dangers to public health inherent in the advertising of claims to cure diabetes, cancer, consumption, and other diseases listed in Clause 1 of the present Bill. The report laid bare the fact that the traffic in that type of advertisement had grown to enormous proportions and produced evidence to show that agencies had been established where the unscrupulous for a sum of money could purchase thousands of names of persons suffering from these complaints. The Select Committee recommended that all advertisements in connexion with these diseases should be prohibited by law, and that was the intention of this Bill. The Select Committee's recommendations went much further than anything contemplated in the present measure. It was true that the report of 1914 was to some extent out of date and that the public had meanwhile received some additional measure of protection through the passing of the Dangerous Drugs Act and the Pharmacy Act. It was also true that reputable newspapers had now established a voluntary form of censorship which excluded the more unsatisfactory type of advertisement; but all newspapers did not come within the scope of that censorship. Examples of the type of advertisement which were still current and which no one could possibly defend were those which claimed to have cures for diabetes and tuberculosis, and which held out by implication the procuring of miscarriage by women. The last named was one of the most harmful and the most fraudulent, because he had been assured by medical opinion that there was no substance known that was in fact effective for this purpose, and if it was effective it could not be so without proving harmful to the health of women.

Efforts had been made in 1920 and in 1931 to deal with these abuses by legislation, but those efforts had proved abortive. The present Bill was of a much more modest character than its predecessors. It represented the greatest measure of agreement that had ever been attained on this problem, and he believed that it would afford the public the minimum amount of protection to which it was entitled. There was no intention, whatever, to discriminate between the unqualified and the qualified practitioner. The removal of the abuses to which he had drawn attention would be as much to the advantage of the unqualified practitioner as to the orthodox medical profession. Orthodox medicine had made enormous strides during the last 100 years, but he recognised the excellent work carried on outside the orthodox medical profession by osteopaths, herbalists, and others. There was no intention in the Bill of placing difficulties in the path of these people. If it could be clearly shown that the Bill did in any way threaten legitimate interests the promoters would be willing to accept amendments.

Captain ELLISTON, who seconded the motion, said the Bill was sorely needed and long overdue. In his experience he had never known any Bill to be so grossly misrepresented as this one. In this Bill the president of the Royal College of Physicians was placed on exactly the same footing as the most humble unqualified practitioner. In early days of the promotion of the Bill it was proposed to give exemption to qualified medical and surgical practitioners, but when they found that there was this feeling about what was called safeguarding the monopoly of the medical profession they said to the British

Medical Association, "Are you anxious for this protection?" and to his surprise the Association replied, "Not a bit." They said, "Place us on the same footing as unqualified practitioners; we ask for nothing more." That struck him as a very remarkable concession. The amendment to which Mr. Lansbury had lent his name said that the Bill "would unjustly penalise unregistered practitioners of various forms of genuine natural healing and would virtually prohibit the employment of many well-tried methods for preventing disease and correcting functional disorders"—in other words that the unqualified practitioner was better fitted to deal with certain conditions than a man who had been trained for the medical profession. The Privy Council through the General Medical Council had laid down what they considered to be the essential requirements of a medical education. When after a minimum period of five years students left medical schools to practise they left behind them chemists, biochemists, biologists, physiologists, bacteriologists, and pathologists carrying on ceaseless research to keep these men abreast of the latest progress in medicine and science. Any educated man knew that most diseases took many varying forms, and that each case demanded individual study and treatment. The patient who interpreted his own condition by the terms of an advertisement might often prevent the discovery of the real disease. It was a common trick of the quack to pick out certain perfectly normal physiological phenomena and to state in these advertisements that these were indications of incipient disease. They thus fraudulently traded on the fears of nervous people, and that was why so much importance was attached by the promoters of the Bill to personal consultation between practitioner and patients. There was not a hospital surgeon in this country but could testify to delayed inoperable cases in which the affected area had been treated with some secret remedy and in which life might have been prolonged or saved by early treatment.

Capt. Elliston said he felt bound to mention the whip that had been circulated to hon. Members to come to the House to-day to defend the pretensions of the gentleman who had offered to the public for many years past an infallible remedy for tuberculosis known as "Umckoloabo." He asked for no greater example of the class of cure which he hoped this Bill would regulate. The report of the Select Committee described him as "a well-known consumption curer who has been denounced in *Truth* for nearly ten years." When the first draft of this Bill appeared in the newspapers this gentleman wrote to all his cases and asked them to write to him (Capt. Elliston) appealing against this very outrageous Bill, which would rob them of their hopes of life. He (Capt. Elliston) received within a few days, less than 18 months ago, 1350 letters from strong supporters of this remedy. He was bound to say that he was considerably shaken, because they gave such assurances of salvation and rescue from death. Finally he put all these letters in a sack and sent them to Dr. Ernest Ward, the secretary of the Joint Tuberculosis Council, and asked for his answer to them. Dr. Ward had not yet been able to complete his investigation of the letters, but he had sent him an interim report. He had so far secured the investigation of 604 cases of which 31 could not be traced; 137 had never been notified as tuberculosis; 122 were in good condition, or fair condition and working; 115 were ill and not working; 62 were desperately ill, some at the point of death; 77 were dead. He had 30 or 40 typical letters written to him less than 15 months ago by unfortunate people who were "cured" and were now dead. The discoverer of this cure had said, "I do not say in my advertisement that consumption can be cured or that consumption is curable, or any such evasive remarks, but I say that I guarantee to cure you if you are consumptive, or to return your money." He did not know whether those 77 people got their

money back but if they did it must have been small consolation.

In conclusion Capt. Elliston remarked that if this Bill interfered with the liberty of any subject then all the public health legislation passed by that House came under the same description.

#### MOTION FOR REJECTION

Sir ARNOLD WILSON moved the rejection of the Bill. He and his friends did not feel that the orthodox medical profession had a monopoly of wisdom; the Bill would tend unduly to restrict the activities of the unorthodox practitioner. The House should pause before it acted on the assumption that most remedies and alleviations not approved by the orthodox medical profession were fraudulent, and that because remedies and treatment were advertised and sold for profit they were therefore deceptive. He agreed entirely that the problem presented by the vast development of advertising in relation to remedies and treatments should be dealt with and if the Minister of Health brought forward a Bill on the lines of that which was introduced last year the House of Commons would give it a patient and respectful examination. Enormous frauds were being perpetrated on the public, but they were not those dealt with by this Bill. Until men and women were able to take independent views and not be misled by propaganda Parliament must protect them as far as it could. But this Bill would do nothing to prevent the credulity of fools. Not one-quarter of 1 per cent. of the money spent on quack remedies in this country was dealt with by the Bill. This Bill did not touch the real problem. It did not touch the cures for asthma, bronchitis, influenza, the common cold, for too much flesh or too little flesh—a very common source of illness—for rheumatism and arthritis, for too little hair on men and too much on women—by no means safe remedies as they saw from scores of cases—for "that tired feeling" at night and in the mornings, shyness and stammering, pimples and skin diseases. He suspected that those who sought these remedies were not persons who had never gone to their local panel doctors, but persons who had not gained relief by orthodox treatment and turned in desperation to other remedies. What was the real remedy? He did not deny that there were evils, but the remedy was to deal with unorthodox practitioners on their own ground. The General Medical Council should accept for the first time in their history—it would be a great decision—the principle that they or the Medical Research Council should accept responsibility for broadcasting on public health at every opportunity without the grudging statement which every medical man who broadcasted at present received from the B.B.C. that he did so at his own risk. The G.M.C. were so frightened of advertisement that they had made it difficult for medical men to broadcast as they should. He would like to see the National Health Insurance Commissioners spend considerable sums of money on sending out leaflets inculcating positive good health instead of presiding over the permanent endowment of ill-health. The campaign for physical education would be useless unless it was accompanied by a campaign in favour of good positive habits of life. The G.M.C. should move with the times. Was the Medical Research Council making the best use of the money at its disposal? Let them have the antidote to quack remedies over the wireless. "Drugs alone will not cure you. You should go to your doctor early." Syphilis and gonorrhoea deserved far more serious attention than they got. It was a shameful fact that there had been no improvement in the death-rate in this respect for the last 10 years. Let the Minister tackle epilepsy seriously. The Eugenic Society stated that the proportion of mental deficiency in the United Kingdom was four times as great as over the northern parts of Europe. That should make us pause. The remedy was not this Bill, but a bold programme of remedial measures. If the Bill became law it would provoke fruitless,

barren, bitter, and purely negative controversy, and would tend further to exacerbate public opinion which was inclined to regard the medical profession with a suspicion which was unfair and unjust.

Mrs. TATE seconded the motion for rejection. She said the Bill would not do what it was designed to do because it was full of loopholes. How was it proposed to prevent the wireless broadcasting from a foreign station in English of advertisements of patent medicines? She deeply sympathised with the object of the provision in the Bill in regard to advertisements for procuring miscarriage of women. She knew how numerous those advertisements were and how serious the matter was. But even if the Bill did away with those advertisements altogether women would not be safer. If these drugs were taken away women would go in increasing numbers to the women who used some sort of instrument—an unsterilised knitting needle or something of that kind. If the Bill were passed there would also be a grave danger that some men whose work might be of immense value to the health of the nation would in future years be debarred from giving such help.

#### THE DEBATE ADJOURNED

Mr. J. G. KERR, speaking as a teacher of biology, said it was necessary to realise the immense amount of natural healing that goes on in the animal kingdom. Before he had had time to develop his argument attention was called to the fact that there were not 40 Members present.

The House was "counted out," the debate on the Bill being adjourned.

#### Public Health (London) Bill

On March 26th, in the House of Lords, Lord BALFOUR OF BURLEIGH moved the second reading of the Public Health (London) Bill. It was, he explained, a consolidation measure promoted by the London County Council after consultation with the Metropolitan Boroughs Standing Joint Committee, and also with the Ministry of Health. Public health legislation was regulated so far as London was concerned mainly by the Public Health (London) Act, 1891, and so far as the provinces were concerned by the Public Health Act of 1875. The law relating to Public Health in London had not been consolidated since the passage of the 1891 Act. Moreover, when that consolidation took place the laws relating to two very important parts of public health legislation—namely, sewerage and drainage and common lodging-houses—were not included in the consolidation. It had now been thought right to bring these within the scope of this Bill. They were at present governed, so far as sewerage and drainage were concerned, by the Metropolitan Management Acts of 1855 and 1862, and so far as common lodging-houses were concerned by the Acts of 1851 and 1853; and all these enactments were now brought within the scope of this consolidation. The public health legislation of London really could only be described at the moment as a jumble. It was in fact a maze, the route to the centre of which was beset with very grave difficulties, and this state of affairs had become an obstacle to good administration. This Bill included the whole of nineteen Acts so far as they applied to London, the whole of four other Acts, except so far as they related to the City of London, and parts of 57 other Acts. The consolidation of 80 Acts of Parliament into one would greatly simplify the administration of the public health legislation of London.

Viscount GAGE, on behalf of the Ministry of Health, stated that the Department regarded the Bill as a valuable clarification of the existing law. Naturally, it would have to be examined with great care by the Joint Committee on Consolidation Bills, but the Government welcomed it in principle.

The Bill was read a second time and referred to the Joint Committee.

#### National Pension Fund for Nurses

In the House of Lords on March 31st, the Royal National Pension Fund for Nurses Bill was read the third time and passed.

#### HOUSE OF COMMONS

WEDNESDAY, MARCH 25TH

#### Medical Examinations at Junior Training Centres

Mr. WILSON asked the Minister of Labour what steps were taken at the juvenile training centres to see that no physical deterioration was taking place; and whether at any period a medical examination took place.—Lieut.-Colonel MUIRHEAD replied: Under the existing scheme local education authorities have power to make their school medical service available to such juveniles attending junior instruction centres as are referred by the superintendent of the centre, and a considerable number of authorities have made such provision. I may add that it has been found in practice that the terms of the statutory scheme governing the provision of those medical services are too restrictive, and my right hon. friend hopes shortly to be able to announce to education authorities generally an amendment of the scheme to enable the school medical officer, if he finds it necessary to do so, to examine boys or girls other than those referred by the superintendent of the course.

THURSDAY, MARCH 26TH

#### Training Camps

Mr. ANDERSON asked the Minister of Labour what arrangements were made for the medical examination of men before being sent to training camps in view of the heavy work performed there; and how many men were rejected as unfit to enter these camps for the three months ended February, 1936.—Mr. ERNEST BROWN replied: Men are not admitted to instructional centres unless found on medical examination to be fit for admission. Men not fit for heavy work are passed for light work only. During the three months ended February, 1936, 940 men, or about 17 per cent., were rejected for training on medical grounds.

Miss WARD asked the Minister of Labour whether he was yet in a position to make a statement with regard to the providing of medical treatment for young men in accordance with the recommendations of the special commissioner.—Mr. ERNEST BROWN replied: I am proposing to set up a number of special local centres in the special areas of a non-residential character, in which men will receive preliminary training before entering either a Government training centre or an instructional centre. In any case where young men are in need of remedial treatment of a simple character, arrangements will be made for them to receive it in connexion with the centre. Pending the establishment of such centres, where it is necessary I shall hope to arrange as a temporary measure for the admission of such cases to one or two of the residential instructional centres where special arrangements for their treatment will be made.

FRIDAY, MARCH 27TH

#### Medicine Stamp Duty

Mr. HOLMES asked the Chancellor of the Exchequer the amounts received for medicine stamp duty in the years 1932-33, 1933-34, 1934-35, and the estimated amount to be received in the year 1935-36.—Mr. CHAMBERLAIN replied: The net receipts from the medicine stamp duty for the years 1932-33 to 1935-36 were as follows:—

1932-33	..	£882,006	1934-35	£709,046
1933-34	..	£777,131	1935-36	.. £730,000*

\* Estimated.

#### Playing Fields and Physical Training

Mr. JOEL asked the President of the Board of Education by what date the inquiry into the adequacy or otherwise of playing fields and physical training arrangements at elementary schools would be completed.—Mr. OLIVER STANLEY replied: In January last the Board issued a

circular on physical education, in which they expressed the hope that the authorities would survey the needs of their areas for playing fields and facilities for physical training and organised games. The authorities are showing great interest in the circular, but I think my hon. friend will agree with me that this matter is not one which can be dealt with by means of a survey, subject to a time limit.

#### Temporary and Voluntary Patients in Mental Hospitals

Mr. SORENSEN asked the Minister of Health how many temporary and voluntary patients received treatment in mental hospitals in 1935.—Sir KINGSLEY WOOD replied: According to the returns 1532 temporary patients and 9744 voluntary patients received treatment in mental hospitals in 1935. The latter figure is, however, subject to a small deduction to allow for persons who may have been admitted to treatment on more than one occasion during the year.

#### Antimony in Enamel Ware

Mr. BANFIELD asked the Minister of Health whether he proposed to introduce legislation to give effect to the recommendation contained in No. 73 of Reports on Public Health and Medical Subjects for the total prohibition of antimony in enamelled hollow-ware.—Sir KINGSLEY WOOD replied: I have under consideration the question of legislation on this subject, but I am not at present able to say when it will be possible to introduce a Bill.

#### Acetic Vinegar

Mr. DENVILLE asked the Minister of Health whether his attention had been drawn to the recent death of a farm labourer at Wainfleet as the result of drinking so-called concentrated vinegar concocted from acetic acid; and, in view of the fact that the sale of acetic acid as vinegar, whether diluted or undiluted, was prohibited by law in almost every country in the world, he would take steps to protect the public from the obvious risks of poisoning which they were running at the present time by prohibiting the sale of acetic vinegar.—Sir KINGSLEY WOOD replied: Yes, Sir. As my hon. friend may be aware, the case referred to has been the subject of a coroner's inquest. The question of the designation of acetic acid mixtures has been noted in connexion with the issues, at present under my consideration, which were raised in the report by the Departmental Committee on the Composition and Description of Food.

#### Public Health Acts Consolidation

Sir ROBERT TASKER asked the Minister of Health whether he contemplated introducing a Bill this session to consolidate the various Public Health Acts; and, if so, he would take the opportunity to make the necessary amendments consonant with technical progress.—Sir KINGSLEY WOOD replied: The Bill to which my hon. friend refers was introduced in another place in the early part of this week. Within the limits applicable to a Bill whose principal object is the consolidation of the existing law, I hope my hon. friend will find in the Bill an affirmative answer to the second part of his question.

#### Abortions and Maternal Mortality

Colonel SANDEMAN ALLEN asked the Minister of Health if the maternal mortality returns from his Ministry included those caused by abortions; and what percentage of those figures were due to illegal abortions.—Sir KINGSLEY WOOD replied: The published statistics of maternal mortality in England and Wales (deaths classified to pregnancy and childbearing) include deaths due to abortion or miscarriage with the exception of those classified to criminal abortion on a coroner's certificate, which are separately shown. Full analyses of all forms of maternal mortality and fatal abortion are annually included in the Text Volume of the Registrar-General's Statistical Review.

MONDAY, MARCH 30TH

#### Temporary Pensions for Neurasthenia and Shell-shock

Mr. ANDERSON asked the Minister of Pensions if he was aware of the ill-effects caused to ex-Service men suffering from neurasthenia or shell-shock by the non-

permanence of their pensions; and if he would arrange for all such pensions that had been given continuously for eight years or more to be made permanent.—Mr. R. S. HUDSON replied: Of the total number of pensions in issue for neurasthenia and shell-shock over 91 per cent. have been made permanent. To make awards permanent in cases where the prognosis is still uncertain would not be in the interests of pensioners, but awards for prolonged periods are given in all suitable cases.

#### Advertisements of Aids for Hearing

Mr. THORNE asked the Postmaster-General whether he was aware of the unfairness to the deaf arising from exaggerated advertising of aids for hearing; if he would decline to accept advertisements for insertion in books of stamps and other post office publications from dealers whose business practices were thus prejudicial to the interest of the deaf; and, before accepting advertisements of aids for the deaf, if he would communicate with the secretary of the National Institute for the Deaf.—Major TRYON replied: I am looking into the question raised by the hon. Member.

#### Anti-Gas Training

Sir GIFFORD FOX asked the Home Secretary (1) whether any local authorities in the London area were operating his anti-gas order and whether he could give the names of such authorities; and (2) if he would state the number of local authorities who had taken any action in the direction of providing gas-masks and providing anti-gas training.—Mr. G. LLOYD, Under-Secretary, Home Office, replied: A circular letter was sent to local authorities on Feb. 24th inviting them to submit the names of employees who should receive training as instructors in anti-gas measures at the civilian anti-gas school. As the circular letter suggested consultation among neighbouring local authorities, it is too early yet to make any statement about the general response to the circular, but I am quite satisfied with the progress that has been made so far. It is hoped by the end of this year that approximately 600 qualified instructors will have passed through the school. The Government has undertaken to provide respirators and protective clothing at the cost of the Exchequer to persons on air raid precautionary services.

#### Compensation for Occupational Diseases

Lieut.-Commander FLETCHER asked the Minister of Labour when it was proposed to ratify the international labour conventions on night work for women (revised), workmen's compensation for occupational diseases (revised), hours of work in the sheet-glass industry, and unemployment provision.—Lieut.-Colonel MUIRHEAD, Parliamentary Secretary to the Ministry of Labour, replied: A Bill to enable the draft conventions concerning the night work of women (revised) and hours of work in the sheet-glass industry to be ratified is now before the House. As regards the conventions concerning workmen's compensation for occupational diseases (revised) and unemployment provision, a Command paper announcing the intention of His Majesty's Government to ratify was presented last January, and the necessary Orders of the Privy Council are now being printed. Subject, in the case of the two former conventions, to the passing into law of the Bill referred to, I anticipate that it will be possible very shortly to notify the Secretary-General of the League of Nations of the ratification of all the four conventions.

TUESDAY, MARCH 31ST

#### Dust in Textile Card-rooms

Mr. RHYS DAVIES asked the Home Secretary whether he was aware that negotiations for the establishment of a voluntary fund to provide compensation for the victims of dust in textile card-rooms had proved abortive; and whether he would now take steps to achieve the object in view by some other means.—Mr. GEOFFREY LLOYD replied: Representations have been received on this matter from the Amalgamated Association of Card Blowing and Ring Room Operatives, who have asked for a deputation to be received. My right hon. friend has asked me to receive the deputation on his behalf, and I

(Continued at foot of opposite page)

## PANEL AND CONTRACT PRACTICE

### Secrecy of Medical Records

THE letter of *Iatros II.* on p. 742 of our last issue may give rise to misapprehension about the confidential nature of entries on medical records. In the case related a patient on the list of Dr. A. in the area of committee X. secured acceptance as a temporary resident by Dr. B. in the area of committee Y. It is stated that the clerk to the Y. insurance committee returned the record form on the ground that it contained insufficient professional details. Now the only details with which an insurance committee is normally concerned are (1) name and address of the insured person and (2) particulars of society or fund membership. Some committees now credit doctors for temporary residents only when a continuation card, showing that treatment has been given, has been submitted, and in such cases the clerk of the committee (or an officer specially deputed by him) would have to satisfy himself that the continuation card actually indicated that treatment had been given. But the clinical notes are no concern of the insurance committee or of its officers. When the present system of envelope medical records was initiated in 1921 the records had to be transmitted in a separate window envelope which allowed the staff of the committee to see the particulars which affected them and nothing else; this rather cumbersome arrangement was terminated in 1923, at the request of the Insurance Acts Committee, on the definite understanding that the records would be handled either by the clerk himself, or by an assistant specially deputed by him, who would be pledged to respect their confidential nature.

As regards the transmission of continuation cards for temporary residents from one doctor to another in sealed envelopes it is a fact that some committees make this arrangement but it applies only where credits are allowed whether treatment is given or not. In the case of other committees the fact of treatment being given on certain dates (a temporary resident is not temporary for more than three months from the date of arrival) must be made known to the committee in order that the treating doctor may be properly remunerated. Possibly Dr. B. could have overcome his difficulty by inserting the dates together with a reference to his having sent a report on diagnosis and treatment direct to Dr. A. Dr. A. could place the report inside the envelope record, as is the practice with hospital reports, reports of the R.M.O., and the like. It is not explained why Dr. B.'s trouble seems to be restricted to temporary residents; does he make entries of treatment of his permanent patients who suffer from ailments which they would prefer should not be divulged?

*(Continued from previous page)*

will arrange to do so at an early date. The position will be further considered in the light of the information furnished by the deputation.

### Milk Designations

Sir GIFFORD FOX asked the Minister of Health whether he had now reached any decision with regard to the suggested designations for milk; and whether in any case he proposed to postpone the coming into force of any order on the subject.—Mr. SHAKESPEARE replied: My right hon. friend regrets that he is not yet able to announce his decision on this subject. He is postponing the operation of the new order until June 1st.

After all the envelope records also have to pass through the insurance committee office if the patient happens to transfer. But since, as Dr. B. admits the medical service subcommittee have twice recommended deductions from his remuneration for delay in returning medical records, he gets over the difficulty by not returning the records.

### Surgery Visitation

A few weeks ago the London insurance committee had an experience (*THE LANCET*, March 7th, p. 574) which led it to ask the medical benefit subcommittee to consider what steps should be taken to satisfy themselves with the surgery accommodation to be provided by an insurance practitioner. The Insurance Acts Committee have had some qualms about this inquiry, and one of their members, pointing out that it was illegal for any surgery inspection to take place before a doctor had his name on the medical list, expressed the view that even if the inspection was voluntary it whittled away something of the right of every qualified practitioner to have his name on the list. The London representatives explained that the surgery accommodation was sometimes of a kind likely to bring the service into disrepute and friendly advice beforehand would prevent this. They may have had in mind the doctor whose consulting-room, in which he also lived, was approached by forty narrow winding stairs, and whose waiting-room was the landing. It was proposed that a medical man from the panel committee and the clerk of the insurance committee should together visit each new applicant and advise him if necessary.

In Edinburgh the practice is for the clerk of the insurance committee to notify the panel committee of doctors asking to be admitted to the medical list, and if there is reason to suppose from a knowledge of the neighbourhood or of the premises that the accommodation is likely to be unsatisfactory the applicant is visited by two members of the panel committee. Birmingham goes farther. In 1922 the insurance and panel committees there appointed a special joint subcommittee to consider questions relating to the efficiency of the insurance medical service, and under the direction of that subcommittee the doctors' waiting-rooms and surgeries were visited by non-medical members of the insurance committee. The local panel committee have agreed to the proposal that surgeries and waiting-rooms should be visited by non-medical members of the insurance committee, but they think that this should apply chiefly to doctors whose premises have not been previously visited, and that the insurance committee itself should decide when it is a question of revisitation. The panel committee have been asked to appoint four members to serve on a joint subcommittee to deal with the matter.

WESTMINSTER HOSPITAL.—The discovery is announced that an old banded iron strong-box in which the great seal of this hospital is kept is of Spanish workmanship of the sixteenth century, and is probably a relic of the Spanish Armada. There is a reference to the box in the minutes of the hospital for 1732-33, and it is thought to have been a gift from Mr. Henry Hoare, the banker, to the hospital on its foundation in 1719. A correspondent of the *Times*, however, believes "Armada chests" to be of late seventeenth or early eighteenth century German origin.

## MEDICAL NEWS

### University of London

Prof. A. K. Henry has been appointed to the university readership in surgery tenable at the British Postgraduate Medical School. Since 1925 he has been professor of clinical surgery in the medical school at Cairo and director of the surgical unit at Kasr-el-Aini Hospital.

Prof. Henry was born in 1886. He studied at Trinity College, Dublin, where he obtained a scholarship and gold medal in natural science in 1909 and graduated M.B. in 1911. In 1914 he came to London as house surgeon and medical registrar at the Cancer Hospital, and in 1915 went abroad to serve as a surgeon, first with the Serbian Relief Fund unit and later with the Royal Army Medical Corps and with the French Army. For his services he was decorated with the Order of St. Sava and made a chevalier of the Legion of Honour. In 1919 he returned to Dublin as assistant surgeon to the Royal Hospital and surgical specialist to the Ministry of Pensions; he also held the post of senior demonstrator in anatomy at the Royal College of Surgeons in Ireland. He took up his present appointment in 1925.

At recent examinations the following candidates were successful:—

D.M.R.

*Part I.*—S. B. Adams, F. R. Berridge, George Friedlaender, J. J. Magner, R. K. Modi, P. J. B. Murphy, H. E. Oford, Ihsan Qainaqchi, Atul Rakshit, B. G. Thompson, J. A. Vote, and A. J. O. Wigmore.

Among those who are to receive honorary degrees from the University in connexion with its centenary celebrations this year are Prof. Einstein, Sir William Bragg, P.R.S., Sir George Newman, Sir Joseph Larmor, F.R.S., Mr. H. G. Wells, Lord Snell, and Mr. S. A. Courtauld (chairman of council of the Middlesex Hospital medical school).

### University of Manchester

At recent examinations J. A. Hobson and Geoffrey Williamson were successful in the first part of the examination for the diploma of psychological medicine.

On May 20th the hon. degree of D.Sc. will be conferred on Dr. John Beresford Leathes, F.R.S., emeritus professor of physiology in the University of Sheffield.

### University of Dublin

At recent examinations at the School of Physic, Trinity College, the following candidates were successful:—

M.D.

Abraham Agranat, James Bell, W. A. Hopkins, and J. C. T. Sanctuary.

M.CH.

C. S. Wilson.

FINAL EXAMINATION FOR M.B., B.CH., B.A.O.

*Medicine.*—W. A. Gillespie, Max Levy, Neville Jackson, G. C. Retz, G. W. Patterson, W. D. Chesney, and John McQuillan.  
*Midwifery.*—\*E. W. L. Thompson, \*Isabelle M. V. Elliott, G. B. Jackson, D. T. Bardon, F. M. D. Byrn, S. E. M'Connell, M. R. W. Spack, J. M. Bryson, H. A. Daniels, H. W. W. Good, R. F. Cantan, J. H. A. Jewell, Francis Keane, J. G. Steinbock, Monty Toohey, B. P. P. Berney, Peter Delap, C. W. Greene, W. E. Connihan, G. L. Daly, Hyman Elliman, D. H. A. Irwin, E. T. McCartney, Margaret Perry, R. J. Sandys, T. S. Agnew, D. P. Beckett, Cecil Eppel, E. D. Mansell, P. J. Mulaney, B. G. Kearon, P. G. Patton, D. S. Toole, and J. G. Cunningham.  
*Surgery.*—\*W. A. Gillespie, D. J. Hayes, G. H. B. Roberts, Benjamin Rogol, J. C. Roux, G. S. Caithness, Bethel Lapedus, F. T. P. Bergin, J. J. Talbot, P. X. O'Dwyer, R. A. Bond, and R. L. Oakes.

D.P.H.

*Part I.*—\*W. C. B. Harrison, H. O. Mackey, P. B. Robinson, R. I. G. Reid, and H. R. Rogers.

\* Passed on high marks.

### British College of Obstetricians and Gynæcologists

The following have been awarded the diploma of the college after examination:—

A. M. F. Batty, Anthea A. Benham, J. A. Bentham, E. C. Bryant, H. F. P. Grafton, J. C. Gregory, Mahmoud Ismail, C. F. Krige, T. E. Lennon, E. W. Martindell, J. K. McCollum, William More, Dudley Racker, William Simpson, I. H. K. Stevens, and Anne E. Williams-James.

### Atmospheric Pollution

An educational exhibition illustrating smoke abatement and atmospheric pollution is to be opened by Sir Kingsley Wood, the Minister of Health, at the Science Museum, London, in October next. It is being designed to show the harmful effects of polluted atmosphere on health, buildings, vegetation, works of art, fabrics, and food, as well as the difficulty and danger caused to aviation. Further information may be had from the National Smoke Abatement Society, Salisbury-square House, Fleet-street, London, E.C.4.

### Hunterian Society

The 116th annual general meeting of this society will be held on Monday, April 6th, at Simpson's Restaurant, Cheapside, at 7.15 p.m. The business of the meeting will begin after dinner, at about 8.30 p.m., and will be followed by a short talk on mild radium therapy by Dr. Howard Humphris.

### London Jewish Hospital Medical Society

The annual oration of this society will be delivered at B.M.A. House, Tavistock-square, London, W.C., on Thursday, April 16th, at 4 p.m., by Dr. Robert Hutchison. He will speak on constitutional medicine.

### Congress of Sanatoria and Private Nursing Homes

The first International Congress of Sanatoria and Private Nursing Homes will be held in Budapest at the end of September. Further information may be had from the committee of the congress, Margitsziget Sanatorium, Budapest.

### Central Association for Mental Welfare

A course for persons engaged in the training of mental defectives in occupation centres or mental hospitals will be held in London from July 4th to 25th. Further information may be had from the secretary of the Central Association for Mental Welfare, 24, Buckingham Palace-road, London, S.W.1.

### British Red Cross Society

The King has become patron of this society, which has had the patronage of the reigning monarch since its foundation in 1870. Queen Mary is the president, the Duke of York chairman of council, and the Princess Royal commandant-in-chief of British Red Cross voluntary aid detachments.

### London County Council Hospitals

It is stated that the council have spent over £1,321,000 on the hospitals in their charge since they took them over from the old boards of guardians in 1930.

### Wingfield-Morris Orthopædic Hospital, Oxford

The Minister of Nepal in London has given £4000 to this hospital to provide a new ward for the treatment of infantile paralysis and £250 for a hard tennis court for the nurses.

### Post-graduate Courses in Tuberculosis

Under the auspices of the Joint Tuberculosis Council a post-graduate course on tuberculosis will be given by the medical and surgical staff of the Royal Chest Hospital, City-road, London, E.C., from May 4th to 9th. Short intensive post-graduate courses on modern methods of therapy in tuberculosis of the respiratory system with special reference to collapse therapy will also be given by Dr. Peter Edwards at the Cheshire Joint Sanatorium, near Market Drayton, Salop. The courses will be held from April 21st to 23rd, June 23rd to 25th, and Sept. 22nd to 24th. Inquiries about them should be addressed to the hon. secretary for the council's post-graduate courses, 8, Christ Church-place, Epsom, Surrey.

### Royal Sanitary Institute

A meeting of this institute will be held in the Guildhall, Swansea, on Friday, April 17th, at 2.30 p.m., in conjunction with the Welsh branch of the Society of Medical Officers of Health. Prof. R. M. F. Picken will open a discussion on the coördination of general hospital services and the provision of additional accommodation, and Mr. Walter Hunter on the coördination of housing, rehousing, and redevelopment under the housing acts with regional and town planning.

On Tuesday, April 21st, at the house of the institute (90, Buckingham Palace-road, London, S.W.), Dr. E. Kaye L Fleming, chairman of the physical education committee of the British Medical Association, will open a discussion on the problem of physical education in schools.

THE President of the French Republic has conferred upon Sir Henry Wellcome, LL.D., F.R.S., the Croix d'Officier de la Légion d'Honneur.

#### Food Production on the Continent

A party of British food chemists is to pay a visit to Holland in May. The tour, which is being arranged by the food group of the Society of Chemical Industry, follows on a similar visit paid last year to Paris and Brussels in which about 40 chemists took part.

#### Lincoln County Hospital

In connexion with the appeal for the extensions of this hospital, it is announced that £55,000 has been spent. The sum of £39,000 has already been received and a further £16,000 is needed at once.

#### Princess Alice Hospital, Eastbourne

Last year 1561 in-patients were treated in this hospital as against 1519 in 1934, but the report submitted at the annual meeting on March 20th showed a deficit on the year's working of £958, and an accumulated deficit of £7686. To meet this deficit the governors have reluctantly drawn upon the endowment fund and some legacy money. The hospital was fortunate last year in the amount it received in legacies, but subscriptions and donations fell by £932. The household box scheme however yielded £5866, which is £523 more than in 1934. The hospital has 116 beds, and the daily number of patients during the year was 108 to 110, but further extensions cannot be considered until the finances improve.

#### Medical Panel for Nurses' Examinations

In our advertisement columns will be found a notice that the General Nursing Council for England and Wales is now seeking the co-operation of doctors in the preliminary as well as the final State examination. Applications are invited (1) from "medical practitioners of good standing who have held a resident or other post on the staff of a hospital and who have experience in teaching" for examinerships in anatomy and physiology, and (2) from present or past members of the staff of hospitals recognised by the Council as complete training schools for nurses, for examinerships in medicine and in surgery. Examinations are held three times a year—in February, May, and October—and the names of examiners are entered on a panel from which those selected to serve are called up as required.

#### A Patients' Library for the Middlesex Hospital

The value of ample reading matter of all kinds to hospital patients was proved by the libraries for wounded soldiers initiated by Mrs. Gaskell during and after the late war, and there are now few hospitals, either voluntary or municipal, without a supply of books. A large modern library, fully equipped with bookcases and space for 10,000 books, has just been installed in the reconstructed Middlesex Hospital as a gift from the staffs of the *Times* and the *Times* Book Club. The presentation was made by Major Astor, M.P., on March 25th, in the presence of the governors, the medical staff, and voluntary workers at the hospital, and many others interested in the library movement. Prince Arthur of Connaught, in accepting the gift, spoke of the need for such a service for the patients and its help in a sound recovery; the gift came most happily and appropriately from the great national newspaper and its admirable book club. Mrs. Beddington, head librarian, traced the development of hospital libraries from sporadic beginnings to 1930 when organised libraries were generally started. Her voluntary staff rose from 8 last year to 18 this year, and in the 12 weeks from Jan. 1st to March 18th they had issued 4557 volumes, including books of all kinds and in many different languages. This library was one of the training schools for voluntary librarians in association with the Guild of Hospital Librarians recently formed for pooling and disseminating information about the formation and running of patients' libraries. On behalf of the donors Major Astor stated that the gift was the outcome of the realisation that the tedium of illness and convalescence can be relieved by the solace of books; they hoped the library would help the patients along the road to recovery and add something to the pleasant recollection they would carry away with them.

#### Royal Society of Medicine

The house and library of this society (1, Wimpole-street, London, W.) will be closed from Thursday, April 9th, to Tuesday, April 14th, both days inclusive.

#### Torbay Hospital

This hospital has only £330 with which to meet its debts of £5868. Subscriptions have again fallen, though a payment of £6555 was made by the contributory scheme.

#### Leeds General Infirmary

In the latest report of this hospital it is stated that in 1935 £4014 was spent on the in-patient treatment of accident cases of which only £2197 was recovered.

#### King's College Hospital

The Duke of York has issued an appeal on behalf of this hospital. To complete the buildings now in progress of erection, including the nurses' home, about £85,000 is needed, while alterations to the X ray department and new apparatus will cost £20,000, and the dental department and its equipment £8000. There is an outstanding debt of £57,000. As a beginning a sum of £79,000 has been collected.

#### Birmingham Hospital Centre

A sum of £770,000 towards the £1,250,000 which it is estimated the new centre will cost has been raised or promised. So far the appeal expenses have not amounted to 1 per cent. A general hospital of 500 beds with nurses' home and the medical school buildings will probably be finished by October, 1937.

#### Royal Free Hospital

The London (Royal Free Hospital) School of Medicine for Women has received an anonymous gift of £11,000 to endow the Free Woman's Lectureship in Clinical Medicine, and Dr. Una Ledingham, assistant physician to the hospital, has been appointed to the lectureship.—The Aldrich Blake travelling scholarship for 1936 has been awarded to Miss Geraldine Barry, assistant surgeon to the hospital.

#### Guest Hospital, Dudley

Workpeople's contributions here have reached a record sum of £8435, an increase of £771. The old buildings are decayed and no longer safe and £30,000 is to be spent in erecting a new administration block. At present there are 107 beds and a waiting-list of 284. The wards now being built will add 56 beds to the accommodation.

## Appointments

BOMFORD, R. R., B.M. Oxon., M.R.C.P. Lond., has been appointed Medical First Assistant and Registrar at the London Hospital.

BROWN, K. R., M.B. Glasg., F.R.C.S. Edin., Assistant Medical Officer of Health for Harrow.

CARTWRIGHT, F. E., M.R.C.S. Eng., D.A., Hon. Anaesthetist to the Ear, Nose, and Throat Department at St. John's Hospital, Lewisham.

HALL, A. S., M.B. Camb., M.R.C.P. Lond., Tuberculosis Medical Officer for Harrow.

HUGHES, D. O., M.B. Liverp., D.P.H., Assistant Medical Superintendent at High Carley Sanatorium, Preston.

MILLIGAN, P. J. W., B.M. Oxon., Resident Medical Officer at Royal Surrey County Hospital, Guildford.

PERRY, K. M. A., B.Chir. Camb., Medical First Assistant and Registrar at the London Hospital.

PHILLIPS, Prof. MILES H., M.D. Brist., F.R.C.S. Eng., F.C.O.G., Hon. Consulting Gynaecologist to the Rampton State Institution, Retford.

SIMPSON, Prof. GRAHAM S., F.R.C.S. Eng., L.D.S., Hon. Consulting Surgeon to the Rampton State Institution, Retford.

TIMMS, W. G., M.B. Liverp., Junior Assistant Medical Officer, Wroughton Hospital, Preston.

TOPHAM, E. J. E., M.B. Leeds, D.M.R.E., Junior Assistant Medical Officer in the Radiological Department of the Manchester Royal Infirmary.

WATSON, JEAN C., M.B. Belf., D.P.H., Assistant County Medical Officer of Health for Warwickshire.

*Middlesex Hospital.*—The following appointments are announced:

GRAY, C. H., M.B. Manch., F.R.C.S., Fracture and Orthopaedic Registrar;

JOHNSON, B. R. M., M.R.C.S. Eng., Anaesthetist; and

ROBERTS, F. W., M.B. Lond., Assistant Anaesthetist.

Certifying Surgeons under the Factory and Workshop Acts: Dr. D. F. SUTTIE (Auchtermuchty District, Fife); Frodingham District (Lincolnshire).

## Vacancies

For further information refer to the advertisement columns

**Ashton-under-Lyne District Infirmary.**—H.S. At rate of £150.

**Aylesbury, Royal Buckinghamshire Hospital.**—Second Res. M.O. At rate of £150.

**Beckenham, Bethlem Royal Hospital, Monks Orchard.**—Two Res. H.P.'s. Each at rate of £175.

**Birmingham, Canwell Hall Babies' Hospital.**—Res. M.O. At rate of £250.

**Birmingham City.**—Sen. Asst. M.O.H. £750.

**Birmingham City, P.H. Dept.**—Res. Asst. M.O. £400.

**Birmingham, Queen's Hospital.**—Bacteriologist and Clinical Pathologist. £600. Also Res. Surg. Reg. £125.

**Bolton Royal Infirmary.**—H.S. £125.

**Bradford Children's Hospital.**—H.P. £100.

**Brighton, Royal Sussex County Hospital and Hove General Hospital.**—Hon. Physiotherapist.

**Bristol Eye Hospital.**—Jun. Res. H.S. £100.

**Bristol Royal Infirmary.**—Hon. Asst. Surgeon. Also Hon. Clin. Asst.

**Burnley, Victoria Hospital.**—H.P. At rate of £150.

**Canterbury, Kent and Canterbury Hospital.**—H.S. £125.

**Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.**—Three Assts. to Out-patients.

**Chelmsford and Essex Hospital.**—H.P. and H.S. Each at rate of £150.

**City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.**—H.P. At rate of £100.

**Cumberland County Council.**—Asst. County M.O.H. and District M.O.H. £800.

**Evelina Hospital for Sick Children, Southwark, S.E.**—H.S. £120

**Exeter, Royal Devon and Exeter Hospital.**—H.S. to Ear, Nose, and Throat Dept. £150.

**General Nursing Council for England and Wales, 20, Portland-place, W.**—Examinerships.

**Glasgow, Stobhill Hospital.**—Res. Anaesthetist. £350.

**Golden-square Throat, Nose, and Ear Hospital, W.**—H.S. £100.

**Gordon Hospital for Rectal Diseases, Vauxhall Bridge-road, S.W.**—Res. H.S. £150.

**Halifax and Royal Infirmary.**—Second and Third H.S.'s. £175 and £150 respectively.

**Hampstead Borough.**—Asst. M.O.H. and Clin. Tuber. O. £750.

**Hampstead General and N.W. London Hospital.**—Cas M.O. for Out-patient Dept. £100. Also H.S. £100.

**Hereford, Herefordshire General Hospital.**—Hon. Anaesthetist.

**Hull Royal Infirmary.**—First H.P. At rate of £175.

**Isleworth, West Middlesex County Hospital.**—Visiting Orthopaedic Surgeon. £3 3s. per session.

**Italian Hospital, Queen-square, W.C.**—Hon. Asst. Surgeon.

**Kent Education Committee.**—Half-time Asst. M.O. £350.

**King Edward Memorial Hospital, Ealing.**—Jun. Res. M.O. At rate of £150.

**Lancaster Royal Infirmary.**—Jun. H.S. £130.

**Leeds Public Dispensary and Hospital, North-street.**—Two H.P.'s. Also Cas. O. and H.S. At rate of £150.

**Leeds University.**—Chair of Anatomy. £1000.

**Leicester City, Education Committee.**—Asst. School M.O. £500.

**Liverpool Sanatorium, Delamere Forest, Frodsham.**—Second Asst. to Med. Supt. £200.

**London County Council.**—Asst. M.O.'s (Grade I.). Each £350. Two Asst. M.O.'s (Grade II.). Each £250. H.P.'s. Each £120. Clin. Asst. £150. Temp. Dist. M.O.'s. £165 and £142 10s. Also Locum Tenens Asst. M.O.'s. Each 6 gns. a week.

**London Homoeopathic Hospital, Great Ormond-street, W.C.**—Hon. Surgeon. Also Hon. Asst. Surgeon.

**London School of Hygiene and Tropical Medicine, Keppel-street, W.C.**—Asst. M.O. for Northern Rhodesia. £840.

**London University.**—University Chair of Anatomy at St. Bartholomew's Hospital Medical College. £1000.

**Macclesfield General Infirmary.**—Second H.S. At rate of £150.

**Maidstone, Kent County Ophthalmic and Aural Hospital.**—Ophth. H.S. £200.

**Manchester, Ancoats Hospital.**—Res. M.O. At rate of £150.

**Manchester, Christie Hospital and Holt Radium Institute.**—Asst. M.O. £400.

**Manchester Royal Children's Hospital, Pendlebury.**—Res. Surg. O. At rate of £125.

**Margate, Royal Sea-Bathing Hospital.**—Asst. Med. Supt. £500.

**Maudslayi Hospital, Denmark Hill, S.E.**—Part-time M.O. £300.

**Metropolitan Hospital, Kingsland-road, E.**—Sen. and Jun. H.P.'s and H.S.'s. Also Cas. O. and Res. Anaesthetist. Each £100.

**National Hospital for Diseases of the Heart, Westmoreland-street, W.**—Res. M.O. Also Out-patient M.O. At rate of £150 and £125 respectively.

**Newport, Mon. Royal Gwent Hospital.**—H.S. and Cas. O. Each at rate of £135.

**New Zealand, Queen Mary Hospital, Hamner Springs.**—M.O. £650.

**Oldham County Borough.**—M.O.H. £1200.

**Penarth, Glam. Llandough Hospital.**—Jun. Res. M.O. £100.

**Poplar Hospital for Accidents, East India Dock-road, E.**—Asst. Hon. Surgeon.

**Preston and County of Lancaster Royal Infirmary.**—Res. Surg. O. £300.

**Princess Beatrice Hospital, Earl's Court, S.W.**—Hon. Clin. Assts. Radium Institute, 16, Riding House-street, W.—H.S. At rate of £150.

**Richmond, Surrey Royal Hospital.**—Jun. H.S. At rate of £100.

**Rochdale County Borough.**—Sen. Asst. Res. M.O. &c. £500.

**Rochdale Infirmary and Dispensary.**—Second H.S. £150.

**Rochester, St. Bartholomew's Hospital.**—H.P. £175.

**Rotherham Hospital.**—H.P. Also Cas. H.S. £180 and £150 respectively.

**Royal College of Surgeons of England.**—Election of Professors and Lecturers.

**Royal Dental Hospital of London, 32, Leicester-square, W.C.**—Hon. Asst. Dental Surgeon.

**Royal National Orthopaedic Hospital, 234, Great Portland-street, W.**—H.S. At rate of £150.

**Royal Naval Medical Service.**—M.O.'s.

**St. Mary's Hospital for Women and Children, Plaistow, E.**—Res. H.S. and Res. H.P. £155 and £150 respectively.

**Salford City.**—Asst. M.O. for Venereal Diseases Treatment Centre. £500.

**Salisbury General Infirmary.**—H.S. At rate of £125.

**Sheffield Children's Hospital.**—H.S. At rate of £100.

**Sheffield University.**—Sorby Research Fellowship. £500.

**Sheffield, Winter-street Hospital.**—Asst. Tuber. O. £350.

**Shoreham-by-Sea, Southlands Hospital.**—Second Asst. Res. M.O. £300.

**Southern-on-Sea General Hospital.**—H.P. At rate of £100.

**Stamford, Rulland and General Infirmary, Stamford.**—H.S. £250.

**Surrey County Council.**—Ophth. Surgeon. £750.

**Swansea General and Eye Hospital.**—Cas. O. £150—£175.

**Taunton and Somerset Hospital.**—H.S. At rate of £100.

**University College Hospital, Gower-street, W.C.**—Hon. Clin. Asst. in X Ray Dept.

**Warwick, King Edward VII. Memorial Sanatorium, Hertford Hill.**—Jun. Asst. M.O. £250.

**Warwickshire and Coventry Mental Hospital, Hatton.**—Two Jun. Asst. M.O.'s. Each £350.

**West End Hospital for Nervous Diseases, Welbeck-street, W.**—Hon. Clin. Asst. to Psychiatric Out-patient Dept.

**West Suffolk County Council.**—Asst. County M.O.H. and Dist. M.O.H. £800.

**Wilkesden General Hospital, Harlesden-road, N.W.**—Hon. Anaesthetist.

**Wolverhampton Royal Hospital.**—H.S. At rate of £100.

**Worcester Royal Infirmary.**—Sen. H.S. £160.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Tutbury (Staffs), Middlewich (Cheshire), Southminster (Essex), and Ribchester (Lancs).

## Births, Marriages, and Deaths

### BIRTHS

**BAIN.**—On March 23rd, at Harrogate, the wife of Curtis Bain, D.M. Oxon., of a son.

**BELL.**—On March 24th, at Bentinck-street, the wife of Arthur C. Bell, F.R.C.S. Eng., of a daughter.

**DAVID.**—On March 24th to Dr. Olivia F. Digby-Smith, wife of T. N. T. David, Welling, Kent—a son.

**DAVIES.**—On March 24th, at Leicester, the wife of Dr. D. Justin Davies, of a daughter.

**EDWARDS.**—On March 24th, the wife of Dr. John A. Edwards, Colnbrook, Bucks, of a son.

**KAY.**—On March 28th, at Ipswich, the wife of R. S. Kay, M.B., Ch.B. Glasg., of a son.

**LUCAS.**—On March 24th, at Devonshire-place, W., the wife of Ernst Lucas, L.R.C.P. Edin., M.D. Munich, Hollycroft-avenue, N.W., of a daughter.

**MEADOWS.**—On March 24th, at Wilbraham-place, S.W., the wife of Swithin P. Meadows, M.D. Lond., M.R.C.P., of a son.

**SANDERSON.**—On March 26th, at Birmingham, the wife of Dr. A. W. Sanderson, of a son.

### MARRIAGES

**EMSLIE-ANDERSON.**—On March 27th, at King's College Chapel, Aberdeen, Harold L. Emslie, M.B., Ch.B., Edinburgh, to Elizabeth Grace, daughter of Dr. John A. Anderson, Aberdeen.

**GROVES-ST. JOHN.**—On March 28th, at St. Cross, Winchester, Dr. John Nixon Groves, to Myrtle St. John, niece of Sir Charles and Lady Close.

**HINDLE-BOYEN.**—On March 25th, in London, Edward Hindle, Rectus Professor of Zoology, Glasgow, to Mrs. Ellen M. Boyen, of Gloucester-gate, N.W.

**MILES-JAMESON.**—On Feb. 3rd, at Chungking, West China, Surg. Lt. Thomas Frank Miles, M.R.C.S. Eng., to Rosemary, younger daughter of the late Engineer Captain T. O. Jameson, R.N., and Mrs. Jameson, of Southsea.

### DEATHS

**ALSTON.**—On March 3rd, at Fish Hoek, South Africa, John Averell Alston, M.R.C.S. Eng., second son of the late Hugh Alston, of Canonbury, London, aged 65.

**CHRISTIE.**—On March 31st, at St. John's Wood, London, Joseph MacNaughtan Christie, C.B.E., M.D. Glasg., F.R.C.S. Edin., Colonel, N.Z. Medical Corps.

**EDER.**—On March 30th, after a short illness, at Brendon House, W.1, Montagu David Eder, B.Sc. Lond., M.R.C.S. Eng.

**ELAM.**—On March 26th, suddenly, George Elam, M.D. Durh., of Barry, Glam.

**GARROD.**—On March 28th, suddenly, at Cambridge, Archibald Edward Garrod, K.C.M.G., D.M. Oxon., F.R.S., formerly Regius Professor of Medicine in the University of Oxford, Consulting Physician to St. Bartholomew's Hospital, aged 78.

**HUME.**—On March 29th, at Brecon, Norman Hallburton Hume, M.B., B.S. Durh., Major, I.M.S., ret'd.

**O'DONNELL.**—On March 23rd, at Seamount Nursing Home, Galway, Dorothy O'Donnell, M.B., B.Ch., dearly beloved wife of Michael O'Donnell, M.D., M.R.C.P.I., Edanam Lodge, Sea-road, Galway.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

THE OVERCLOTHED BOY

By JOHN RIDDELL, M.D. Glasg., D.P.H.  
 ASSISTANT MEDICAL OFFICER OF HEALTH FOR THE  
 COUNTY OF STIRLING

"A CHILD should be clothed lightly, so that its activity is not hindered, but warmly enough so that its heat-productive power is not over-taxed." In these words Sir Leonard Hill<sup>1</sup> gives an objective excellent to strive for, but very difficult to reach. How many parents are governed by any such criteria in considering the clothing of their children? How many doctors even?

The probability is that the main factor influencing choice is "fashion." This almost entirely decides the types of garment to be worn. Individuality can only exist in minor differences in detail and in quantity, as expressed by the number of layers of clothing. Fortunately, since the beginning of the present century, fashion has tended to encourage approach towards the above standard. Perhaps it may sometimes have been made an excuse for an excessive zeal in discarding clothing, but on the whole much good has resulted. This is especially so in the case of girls. With boys, fashion has changed but little, and far too much clothing is still worn. An attempt should be made to remedy this.

To illustrate the changes which have taken place, and also those which still require to be effected, the following inquiry was undertaken among pupils attending schools in Stirling. The scholars come almost entirely from mining and working-class families. They were weighed with and without their indoor clothes (excluding shoes or boots) first at the end of August and again in the latter half of December. The average temperatures (Fahrenheit) over the periods of the examinations are given below—representative samples of summer and winter weather.

	Maximum.		Minimum.	
	Open.	Screen.	Open.	Screen.
August ..	72.5	61.1	49.0	48.8
December ..	44.5	37.4	29.0	29.6

With regard to the amount of clothing worn, very striking differences at once become apparent as shown in Table I.

TABLE I.—Weight of Clothing

Weight of clothing in lb.	Number of cases in—			
	GIRLS.		BOYS.	
	Summer.	Winter.	Summer.	Winter.
1-1	43	6	1	—
1-1½	104	29	15	—
1½-2	94	38	43	5
2-2½	50	77	85	18
2½-3	21	52	92	27
3-3½	12	43	105	47
3½-4	2	23	103	57
4-4½	—	16	68	69
4½-5	—	3	34	72
5-5½	—	2	28	71
5½-6	—	1	7	37
6-6½	—	1	4	32
6½-7	—	—	1	18
7-7½	—	—	—	10
7½+	—	—	—	11
Total ..	326	291	586	474

The differences between the sexes and in different seasons are noteworthy, but even with the same sex in the same season, individual variation is apparently very great. Universal factors which might affect this are age, height, and weight, the two latter being to a certain extent, of course, correlated with the former.

XII. to XV.	326	—	—	1.8	291	—	—	2.7

Y.=years. M.=months.

Table II. shows the effect of varying age and brings out the contrast between boys and girls. While the amount of clothing worn by girls changes very little with increasing age, that worn by boys increases markedly. In both cases, however, the weight of clothing expressed as a percentage of the clothed body-weight tends to decrease slightly with advancing age.

Table III. shows the relationship between height and weight of clothing, while Table IV. shows the relationship between the latter and clothed weight of the children. Again the amount of girls' clothing varies little, while that of boys increases, with both height and weight.

The present investigation shows, then, that girls between the ages of 12 and 15 years wear clothing amounting to about 1.8 per cent. of their weight in summer and 2.7 per cent. in winter, while the clothing of boys between the ages of 11 and 16 years amounts to about 3.9 per cent. of their weight in summer and 5.1 per cent. in winter or roughly twice that of the girls.

Comparing this with the results of previous inquiries is both interesting and illuminating. Quetelet<sup>2</sup> in Paris in 1835, presumably working in conditions comparable to our summer temperature, allowed 5.5 per cent. of the gross weight in the case of boys and 4.2 per cent. for girls. Bowditch,<sup>3</sup> of Boston, in 1875 found that the average amount to be allowed for clothing over the whole year was between 9.9 per cent. and 7.9 per cent. for boys and 5.8 per cent. and 7.3 per cent. for girls, depending on the age (similar to those in the present investigation), but he almost certainly included footwear as part of the clothing. Schmidt Mounard<sup>4</sup> in 1901 concluded that the weight of clothing in the case of boys from six to fourteen years of age was 7.75 per cent. of the gross

Several cases were omitted as they were outside the weight limits.

weight and in the case of girls 8 per cent. In 1921 Baldwin<sup>5</sup> noted a change in conditions and stated: "It has been found that the weight of children's clothing worn at the present day is considerably less than the earlier estimates by other investigators. Also the range of variation in the clothing of different children and at different seasons is not so wide as has been supposed." In 1923, in conjunction with Wood,<sup>6</sup> he gave the weight of clothing as 4 per cent. of the nude weight in the case of boys and 2-2.5 per cent. in the case of girls.

The trend is therefore perfectly definite, but it has not been so marked in the case of boys as with girls. It is now commonly accepted that reduction of clothing, allowing more benefit to be derived from the sun and air, not only does no harm, but develops an increased immunity to those diseases commonly attributed to the influence of cold. On the other hand, it must only be put forward as part of the campaign for better health. To quote Leonard Hill<sup>7</sup> once more: "The scanty clothing of women should not result in overheated stuffy houses and hotels in which the air becomes polluted with dust and microbes which occasion respiratory disease. The clothing should be the lightest that can be borne without the wearer being pinched with cold or feeling the need of artificial heat when the weather is mild. It should not be so heavy as to reduce the heat production of the body to a lower level and interfere with the taking of vigorous exercise. . . . It is only the old, the underfed and feeble who require very warm clothing, those whose fire of life is weak and cannot be fanned up by vigorous exercise."

What lead is the medical profession giving to help the boys?

## ESTIBIUS PSYCHALETHES

William Coward, who more than once found it convenient not to append his name to his works, but who originally employed the above curious pseudonym, is the subject of an essay in a recent issue of the Annals of Medical History.<sup>1</sup> His memory is worth rescuing because he was such a singular man. He was born at Winchester and in Dr. Burton Chance's essay he is credited with having been at Winchester College. He was at any rate a classical scholar, graduated in arts from Wadham College, Oxford, in 1677, and was shortly afterwards elected a fellow of Merton when he graduated in medicine. He seems to have practised in Northampton for a time and also in London, but no evidence as to his having obtained any regular position is forthcoming, though he was at one time "a candidate for qualification" at the Royal College of Physicians of London. His literary performances make curious reading. He started authorship by publishing a Latin version of Absalom and Achitophel which was not accepted by the University of Oxford for publication, but was

<sup>1</sup>Chance, B.: Annals of Medical History. New York: Paul B. Hoeber, 1935, vol. vii., p. 559.

afterwards published for him by a friend under the assumed name of Walter Curle. The effort brought him no great credit and he turned to medical literature, writing several books of a theologico-metaphysical sort, one of which, on volatile ferments, received the approval of the president and censors of the Royal College of Physicians of London. With one of his productions he obtained real publicity, and his Greek pseudonym suggests its purport in a vague manner. This was an essay on mortality entitled *Second Thoughts Concerning the Human Soul*, and its views aroused such serious controversy that Coward was called to the bar of the House of Commons to explain, and if necessary apologise for, his doctrines. He professed his readiness to the House of Commons to recant any views which might be considered irreligious or immoral, and it will be seen from the title-page that he would have much to explain to the orthodox thinker of the day. It runs thus:—

“SECOND THOUGHTS

Concerning

HUMAN SOUL,

Demonstrating the Notion of Human Soul,

As believ'd to be a SPIRITUAL IMMORTAL

SUBSTANCE, united to Human Body,

To be a Plain

HEATHENISH INVENTION,

And not Consonant to the Principles of

PHILOSOPHY, REASON, OR RELIGION;

But the Ground only of many

Absurd, and Superstitious Opinions,

Abominable to the Reformed Churches,

And Derogatory in General to

TRUE CHRISTIANITY”

The House considered that the book was offensive and ordered it and other of Coward's works to be burnt by the common hangman. As further editions of the incriminated works appeared it may be presumed that the tenets and theories were modified; certainly his zeal for authorship remained, and he returned to the composition of religious poems. Lastly, in his work on diseases of the eye, entitled *Ophthalmiatria*, he came into medical notice. This small book written in Latin appeared in 1706 and according to Dr. Chance the author must have been considerably indebted to others for his representation of the knowledge of his day, but his theological views probably made the text more unintelligible. Sir Hans Sloane undertook the supervision of the proofs and appears to have differed with the author on religious points. The alteration, as narrated by Dr. Chance, gives the honours to Coward who did not see his way to making certain modifications in order “to add something in commendation of the ‘tender consciences’ of physicians in point of religion.” Such modern ophthalmologists as have had the equipment and curiosity to peruse Coward's contribution to science have found nothing in his pages to show any original research or practical teaching. But it seems that from the bibliophile's point of view his books have the value of their rarity.

#### WILLESDEN WOMEN'S WELFARE CENTRE

WE have received the first report of this new centre which covers the period from June to December, 1935. It is a promising little document. Those behind the birth control clinic appealed at the start for £200, a sum which they felt would justify them in taking action. The immediate return amounted to only one-third of that sum, but none the less those responsible for the movement felt that the need for assistance in the district was such that a commencement ought to be made; already they are able to prove that valuable work is being done, and the Willesden borough council has come to their assistance by providing cheerful and hygienic premises. But the rent has only been paid in accordance with a special donation, and very little money is left. Any contribution, therefore, will be gratefully received by the honorary treasurer, Mrs. I. Bedford, Lake View, The Vale, Hampstead.

#### “MUSIC HATH CHARMS—”

THE Rev. S. C. TICKELL, writing from the vicarage, Latton with Eysey, calls attention to the influence of music in cases where the symptoms are dependent on mental strain and anxiety. No doubt he has had in mind that David's first appearance in biblical history is in the character of “a cunning player on the harp,” when it is recorded that he performed so well that Saul, who was troubled with an evil spirit from God, was refreshed and was well—at any rate for a period though his relapse was dramatic. Mr. Tickell will have on his side many churchgoers when he accuses the musical services of the church of being too dreary and didactic to minister to the diseased mind, and he suggests that this position could be remedied if organists had an opportunity for suitable improvisations which might attain the wider circulation of being broadcast. Mr. Tickell has a great advocate on his side when extolling music as mental refreshment, for Burton in the “*Anatomy of Melancholy*” devotes considerable space, and much of his quaint erudition, in enlarging on the theme. Burton's great work must rank high in that considerable list of classics which many quote, which more talk about, and which few read. An essay by Dr. J. L. Miller in the current issue of the *Annals of Medical History* should persuade readers to turn to Burton's deeply interesting and often highly amusing pages. Undoubtedly the book is made difficult reading by the prolific citation of the classics, and not those read as school books, but as a rule the passages are not difficult to follow taken with their English contexts. Burton was a learned priest, not a doctor, but it is always admitted that in his fantastic way he was a considerable psychologist. Dr. Miller has evidently read the “*Anatomy of Melancholy*” with gusto, as Sterne and Lamb, and possibly even Milton, have done before him. And those who are encouraged by his essay to follow suit will be rewarded.

#### FATHERS AND MATERNITY

FOR some years fathers' councils and committees have been springing up here and there in connexion with infant welfare centres and similar institutions. The Central Union of Fathers' Councils was formed to coördinate their activities, and it held its fifth annual conference in London on March 25th. Dr. G. F. Buchan, medical officer of health for Willesden, who presided, said that mothers should have at their disposal the best and most efficient service the community could provide. The maternity hospital should be in the charge of an obstetric specialist. He instanced the situation in Willesden, where in the municipal maternity hospital there were 64 beds, (comprising 9 antenatal, 4 isolation, 43 lying-in, and 8 labour beds). The maternal death-rate at the hospital during the last five years had been 1 per 1000, and in the last 2500 cases there had been no deaths at all.

Speaking on the psychological aspect of maternal welfare Dr. Grantly Dick Read stated his conviction that the rôle of the man was essentially that of the protector and provider, while the nature of woman was primarily dependent, a quality which became particularly apparent during pregnancy. The expectant mother relied on her husband not only for maintenance but also for a sympathetic understanding of her own state of mind. It was important for the husband to express pleasure and satisfaction at the prospect of a child. “The man who does not want his coming child may start a series of thoughts in his wife's mind which will make pregnancy a misery,” said Dr. Read. “Nothing is more likely to cause unsuccessful childbirth than unhappiness.” The father should assume the responsibility of ejecting relatives who told scare stories, and the expectant mother should not be allowed to hear talk of maternal mortality, for she was extremely suggestible.

## NEW PREPARATIONS

**NOVURIT SUPPOSITORIES.**—Novurit is an organic mercurial diuretic akin to Salyrgan, and containing 5 per cent. of theophylline. It is inactive when taken by mouth and has occasionally caused local pain when given in the usual way by intravenous or intramuscular injection. The manufacturers (Chinoin Chemical and Pharmaceutical Works, Hungary) have therefore devised suppositories containing 0.5 gramme of Novurit in cocoa-butter for use wherever injections of the drug are inadvisable or inconvenient. In our issue of Jan. 4th (p. 17) Dr. John Parkinson and Dr. W. A. R. Thomson reported a trial of this suppository in ten cases of congestive heart failure, from which they concluded that it is a safe and effective diuretic—"an addition of value in the treatment of dropsy." Given by rectum Novurit does not evoke quite so large a flow as when injected intravenously, but rectal administration is often more practicable, and no toxic or irritative action was observed in these ten cases. The manufacturers state that there are no side-effects and that the efficacy of the drug does not diminish on prolonged use; they recommend it for cardiac oedema, fluid in serous cavities, nephrosis, eclampsia, and other conditions—but not in cases with diarrhoea or acute or chronic glomerulonephritis. The suppositories are obtainable in this country from Messrs. W. Martindale, 50, Wigmore-street, London, W.

**NORMO-GASTRINE** is a preparation of aluminium silicate made up in tablets and intended for the treatment of excessive gastric acidity. The main advantage claimed is that it is not alkaline and does not operate against hydrochloric acid in the low percentages found in the normal stomach; nor does it affect the activity of pepsin. Its use is said to obviate the disadvantages associated with generation of carbon dioxide in the stomach or with imperfect digestion due to weakening of the gastric juices. The makers are Burgoyne, Burbidges and Co., Ltd., East Ham, E.6.

**LUTEOANTIN**, sold by Gedeon Richter (Great Britain) Ltd., 1, Hardwick-street, E.C.1, is a preparation of gonadotropic hormone obtained from the anterior pituitary, and its luteinising power is said to be several times as great as that of similar hormones extracted from pregnancy urine. In clinical practice it is meant to serve as substitute for the more expensive corpus luteum hormone (progestin), and it is held to be useful in various forms of excessive uterine hæmorrhage, and in dysmenorrhœa, hyperemesis, and habitual and threatened abortion. Luteoantin is issued in double ampoules, one of which contains the powdered hormone and the other a solvent. Each ampoule is stated to contain 50 mouse units.

**ANAHÆMIN B.D.H.**—Last year Dakin and West recorded a substantial advance towards isolation of the active principle which cures pernicious anæmia. They extracted from liver the light buff-coloured powder, soluble in water, which is now known as anahæmin, and in our issue of Feb. 15th Dr. Ungley and Profs. Davidson and Wayne were able to report excellent clinical results from the use of this concentrated extract as prepared in this country by the British Drug Houses Ltd. (London, N.1), who now market it under the name Anahæmin B.D.H. The substance is so potent that the manufacturers believe that a monthly injection of 200 mg. (or 2 c.cm. of the solution they supply in ampoules) will probably be sufficient to maintain a normal blood picture, and in view of this small dosage they claim that the use of anahæmin is not only convenient but also economical. The preliminary observations of Dr. Ungley and his colleagues suggested that the new preparation "may prove to be at least as potent as other liver extracts in the treatment of the neurological manifestations of pernicious anæmia," and it is hoped that it may be found to possess all the therapeutic properties of liver in this disease.

Messrs. Allen and Hanburys Ltd. announce that **EUCORTONE** (extract of suprarenal cortex) is now to be issued in a more concentrated form, having 2½ times the potency of the previous preparation and a correspondingly lower dosage. It will be supplied in ampoules of 10 c.cm. instead of 25 c.cm. and their price will be 30s. instead of 36s.

From their new premises at Greenford **GLAXO LABORATORIES LTD.** have issued a revised catalogue including particulars of their detoxicated vaccines, vitamin and antiviral preparations, pharmaceutical products, and foods. A price list gives the discount charges to the medical profession.

## ADDRESSES AND ORIGINAL ARTICLES

**MEDICAL PROBLEMS IN MINERAL METABOLISM\***

R. A. McCANCE, M.D., Ph.D. Camb.,  
F.R.C.P. Lond.

ASSISTANT PHYSICIAN IN CHARGE OF BIOCHEMICAL RESEARCH,  
KING'S COLLEGE HOSPITAL, LONDON

### III.—EXPERIMENTAL HUMAN SALT DEFICIENCY

IN my second lecture I tried to give you an account of the importance of sodium chloride deficiencies in clinical medicine, and it must have been obvious to you how incomplete is our knowledge of the subject. It is perfectly true that a great deal has been written on the matter, but much of it will not bear scientific criticism. Almost all the salt deficiencies which have been produced experimentally have been accompanied by a forced loss of water, alkalosis, starvation, Addison's disease, or diabetes, and it is difficult to disentangle the effects. Patients with salt deficiencies are generally too ill to be studied experimentally, and there is generally the complication of some coincident disease. It occurred to me that if I could produce a simple sodium chloride deficiency in a normal animal or person, uncomplicated by forced dehydration, change of reaction, or any other concurrent morbid process I might be able to throw some light on the pathology of this group of diseases. A salt-free diet combined with sweating was the obvious method to try first. None of the ordinary laboratory animals are available for this sort of experiment since they do not sweat, but in any case man is the best experimental animal to use in this type of research, so I decided to employ him. Continuous loss of hypotonic sweat would of course lead to an over-concentration of the sodium salts in the body fluids, but my intention was to replace the water as it was lost by the simple process of giving more to drink, so that the net result would merely be a loss of sodium chloride and bicarbonate. I planned to follow the development of the deficiency by noting any symptoms or physical signs that might appear, and by studying the composition of the blood and the intake and output of mineral salts and nitrogen. As you can imagine, experiments of this sort are not very easy to carry out. I could not possibly have done them by myself and any success that I may have had has been the result of team-work. I have had a great deal of help from Miss E. M. Widdowson and my wife. I could never have managed the technical work but for the assistance of L. R. B. Shackleton, A. W. Haynes, and R. J. Millar, and I should like to take this opportunity of saying publicly how much I have appreciated all this coöperation.

#### Conduct of the Experiments

There have so far been four subjects. The first was one of the women medical students, P. M. Edwards, who very kindly volunteered to be the pioneer. We never succeeded in making her really salt-deficient.

After I had got the technique through its teething troubles I made myself sodium-deficient and I have since done it a second time. Between my two exploits

we have carried out experiments on two medical students from Oxford, R. B. Niven and D. Whitteridge, and I could not have wished for better or more willing helpers. There have therefore been five main experiments of which the first was a semi-quantitative trial, the second and third were fully quantitative balance experiments, and the fourth and fifth were carried out partly to confirm previous observations and partly to open up fresh ground.

We have found that it takes us about a week to make the subjects seriously deficient. We have generally maintained them in this condition for 3 or 4 days, so that the deprivation periods have all lasted about 11 days. The recovery periods have varied from 24 hours to 7 days according to the object of the particular experiment.

We have unfortunately no diet kitchen at King's College Hospital, so that it was impossible to have our special low salt diets prepared there, but my wife very kindly offered to do this for us, so I slept and ate at home and two of the other subjects have also stayed in my house during their experiments. We have lived mostly on salt-free "casein" bread, synthetic sodium chloride-free milk, salt-free butter, thrice boiled vegetables, jam, fruit, home-made salt-free shortbread and toffee. All the food was carefully weighed. The milk and bread were designed for these experiments<sup>20</sup> to enable a reasonably high protein intake to be combined with a salt-free diet, and both are quite palatable. I am very much indebted to Miss B. Swayne for making this bread for us. I experimented with rather more fancy dishes such as washed mince curried, but they were not a great success. During the recovery periods Niven and I ate regulated quantities of highly salted foods such as anchovies and bacon and also small weighed amounts of pure sodium chloride. We ate the bacon out of the frying pan to avoid losing any of its salt, and then, to make assurance doubly sure, we washed out the pan with a little hot water and drank the washings. All these salted foods and also all special foods such as the washed mince and vegetables were analysed. The composition of other foods was taken from our own food tables.<sup>10 12</sup>

We used a full length radiant heat bath as a sweating chamber. A mattress with two pillows at one end was placed on the floor and over all an 8 ft. strip of red rubber sheeting. The bath was placed on the sheeting. The open end of the bath, which was of the usual "tunnel" type, was closed by hanging a second piece of sheeting over it. The heat was always switched on half an hour before the subject got into the bath. Sweating under these conditions may be extraordinarily profuse. The subject usually spent two hours simmering inside with the heat on, followed by 10 minutes with the heat off, and during this time it was quite usual to lose 2 litres of water. Whitteridge once lost over 3 litres. 500-1000 c.cm. of sweat had generally been scooped off the sheeting before the subject came out. It is not very uncomfortable inside provided perspiration becomes profuse at a reasonably low body temperature: between 100° and 101° F. suited me very well. I sometimes got considerable abdominal discomfort towards the end. Whitteridge felt very sick once or twice after getting out, but Niven and Miss Edwards rather enjoyed the performance. The two hours and ten minutes in the bath passed quickly. There was really plenty to do, temperatures to take, notes to be made, measured amounts of water to be drunk, and so on. When

\* The Goulstonian lectures for 1936, delivered before the Royal College of Physicians of London on March 5th, 10th, and 12th. Lectures I. and II. appeared in previous issues.

time was up the subject crawled out and stood in an enamel tub while he was washed down from head to foot with a jet of warm distilled water. This was rather pleasant.

When the subject was out of the bath, washed down, dried, and dressed again, and all possible liquid sweat had been bailed off the sheetings, these, and the parts of the air bath touching them, were washed down with distilled water into the enamel tub. The contents were then evaporated down for analysis.

All urines and faeces were preserved for analysis, the latter in periods of several days at a time. To collect the insensible perspiration we wore special underclothes (day and night) which had previously been washed four or five times in distilled water. At the end of the deprivation period we took these off and washed them out in distilled water till the washings were again chloride-free. The washings were evaporated down and analysed. The underclothes were then dried, and we put them on again till the experiment was over, when they were again washed and the washings analysed. We shaved, but were very careful to get the lather off, and we used no soap anywhere else except for our hands, so that we did very little domestic washing of any kind.

### Symptoms and Signs \*

Salt deficiency produces an obvious change in the facies. The temporal hollows and the cheeks fall in, and the eyes seem tired and sunken. I think we all looked rather worn and ill towards the end of our experiments.

There is always a loss of weight, to which I shall refer again later. We have all noticed a peculiar sensation in the mouth, which is present all day long. This is not thirst, although Miss Edwards considered that it was so, and drank freely in her attempts to obtain relief. All food seems to be tasteless, even fruit, which contains no salt and is normally eaten without any. I found that cigarettes had lost all their flavour. At the same time an apple would never be mistaken for a pear. The characteristic flavours are there, but they are blunted. I am afraid we have not been able to make very much headway with the investigation of this symptom. At the close of my second experiment I tried the effect of washing out my mouth with salt and water and found it very refreshing, and thought my sense of flavour was thereby restored. We have examined the resting saliva on several occasions and have not been able to detect any important change in composition. I believe these observations are of clinical interest, for I think it is quite possible that the "thirst" so often complained of by patients with intestinal obstruction may really be this curious loss of taste brought about by salt deficiency. At all events Mr. J. B. Hunter has informed me that a patient's "thirst" is often relieved by hypertonic saline in amounts too small to relieve the general dehydration.

Anorexia and nausea are prominent symptoms. I was never hungry, and I think this is true of all the other victims, but Niven and I always managed to get through the prescribed rations for the day. Whitteridge was sick one evening after sweating. This nausea is not at all the same as "indigestion," from which none of us suffered. Indeed, the nausea is not noticeably related to food, and my feelings of sickness often passed off after I had managed to force a little food down my throat. The nausea and lack of appetite were not due to achlorhydria. The response to histamine, moreover,

when we were salt-deficient was almost exactly the same as it was when we were in normal health. None of us suffered from constipation.

We have all noticed that our water metabolism was not normal. After drinking a large amount of water no diuresis would develop at the expected time, but then, hours later—possibly during the night—the diuresis would begin. On one occasion, for example, Whitteridge wished to produce a diuresis for some kidney function tests to be carried out at midday. He began to drink at breakfast time, but the diuresis was quite moderate during the tests and fell off later. Between 10 P.M. that night and 8 A.M. next morning, however, he passed 1800 c.cm. of urine!

We have all suffered a good deal from cramps except Miss Edwards, who escaped, I think because her deficiency was relatively slight. These cramps are most characteristic. They are not the severe localised type described by Moss<sup>13</sup> and others<sup>2,19</sup> in miners and stokers. Our cramps were relatively mild and easily controllable, but any muscle suddenly brought into action was liable to spasm. Coughing produced cramps all round the chest; yawning, cramp in the floor of the mouth. I think the most characteristic were the cramps in the fingers that came on whenever one tried to use a pipette or a pair of forceps.

We have all suffered from excessive fatigue and a general sense of exhaustion. Towards the end Whitteridge felt wretched enough to go to bed as soon as the day's experiments were over, but I fancy I felt the physical strain more than the others. I noticed it particularly in going up the two flights of stairs to the laboratory, and the effort was accompanied by a sense of breathlessness and a most unpleasant feeling of constriction across my sternum, which compelled me to pause and rest several times on the way up. Once or twice I found my arm getting tired while I was shaving, and one day at breakfast I actually noticed my jaws getting tired eating toast! On the other hand, I think my mental faculties were more or less normal, whereas Whitteridge and Niven both got into an extraordinarily interesting state, in which they were content to sit and do nothing in a chair, sometimes for hours on end. They both commented on feeling "slow in the head." They reacted very slowly and apathetically to any suggestions, pleasant or unpleasant, made to them, and their whole mental processes appeared to be dulled. Whitteridge, for example, was quite unable to make any notes or even label his specimens. Roused up by someone and presented with a suitable vessel he would produce the specimen of urine demanded, set it on the bench and settle again in a comfortable chair without occupation of any kind. I am sure this mental state would repay investigation by those competent to do so.

We have not noticed any change in the resting pulse-rate, but the volume became small. All the subjects had normal blood pressures throughout, and we have failed to detect any fall in them, which I think is an important observation. We must conclude that even severe salt deficiency lasting for 6-8 days need not, and does not, alter a normal person's blood pressure.

The resemblance between some of the symptoms which I have been describing and those of Addison's disease are, I think, too striking to be a coincidence. I was not expecting anything of the sort when we began our experiments. Our own weakness, languor, nausea, and anorexia drew my attention to the possible resemblance because these are the text-

book symptoms of Addison's disease. My own breathlessness and cardiac distress and Whitteridge's and Niven's mental apathy seemed to me to be something fresh. I have since discovered Rowntree and Snell's descriptions of clinical Addison's disease based on 108 authentic cases seen at the Mayo Clinic. They say: "The disturbance is evidenced by . . . palpitation and dyspnoea, particularly on exertion. Heart consciousness and occasional precordial angina-like pains are precipitated by exercise." I felt just like this. They also describe mental symptoms of languor, patients "feel disinclined for physical or mental effort . . . they lose their ability to concentrate and drowse constantly." They might have been describing Whitteridge.

Further, our failure to produce a normal diuresis by drinking water recalls the fact that patients with Addison's disease suffer in exactly the same way.<sup>15</sup>

Pigmentation and a subnormal blood pressure, however,—two of the well-known signs of Addison's disease—were not observed in our experimental salt deficiency. I think it possible that both these signs may be due to the absence of the medullary rather than the cortical hormone. In any case pigmentation could hardly have been expected to develop in ten days. A very low blood pressure, moreover, is not invariable in Addison's disease<sup>15</sup> and there is always the possibility that a combination of several factors may be necessary to produce it.

Hypochlorhydria and achlorhydria are said to be common, although by no means invariable, in clinical and experimental Addison's disease.<sup>4 18</sup> We have not encountered this, nor was it to be expected, since it has been shown in normal persons and animals that hypochloræmia and anhydræmia caused by the removal of gastric juice itself do not produce achlorhydria.<sup>3 5 7</sup> Cramps are much less common in clinical Addison's disease than they were in these experiments, but I think that this may very well be due to the former's relatively chronic nature. Our cramps were mild compared with those of stokers, and I would correlate this with the fact that in our experiments the salt was removed comparatively slowly. With still slower desalting we might have missed the cramps altogether. I have often wondered if the well-known cramps of severe diabetes are really cramps of sodium deficiency, but I have no concrete evidence on this matter.

### Loss of Sodium and Chloride

The sodium and chloride lost could only be assessed by measuring carefully the intakes and outputs throughout the experiment. I attempted to do this on myself and Niven.<sup>9</sup> Niven's intake of sodium was of the order of 70 mg. per day. Mine was lower, only some 40 mg. per day. Niven lost 23,314 mg. of sodium, gross, of which nearly 18,000 was lost in the sweat, about 4000 in the urine, and the remainder in the faeces, insensible perspiration, and blood taken for analytical purposes. His net loss of sodium was 22,516 mg. His net loss of chlorides amounted to 27,028 mg. Now, in the first place, where did all this sodium and chloride come from? Some, of course, from the plasma, for, as I shall show you presently, there was a fall in serum sodium and chloride and also a fall in plasma volume; but the whole of Niven's plasma only contained some 8300 mg. of sodium and 9000 mg. of chloride—clearly not nearly enough to account for the loss. The red blood-cells contain chloride, but their loss of this ion was measured and found to amount only to a little over 1000 mg. Red blood-cells contain

very little sodium, and muscle-cells practically no sodium or chloride. The amount supplied by them may be neglected. To some extent the sodium and chloride lost may have come from the cells of glandular organs such as the kidney, or the brain, but the main source must have been the so-called extracellular fluids, lymph, intestinal secretions, interstitial fluids, and so on. These must have been very greatly reduced in volume. In the second place, what percentage of his total body sodium and chloride did Niven lose? This is difficult to answer because we have no accurate information as to the amount of sodium or chloride in an adult's body. I believe the best figure is obtained from a study of the amount of chloride in a number of the smaller animals of all ages, and the few analyses of fetuses and new-born infants which have been made.<sup>14 21 22</sup> Taking this evidence for what it is worth, Niven contains about 90,000 mg. of chloride. He lost 27,000 mg.—i.e., about 30 per cent. of his total chloride. His losses of sodium were undoubtedly of the same order, so that you see he was seriously depleted.

During the recovery period Niven regained almost exactly as much sodium as he had lost during the deprivation period, so that as regards sodium the *status quo* had practically been restored. By this time, however, he had more than made good his loss of chloride (Table I.) for his net gain had been nearly

TABLE I

	22,295				
Net gain = 34,738 mg.					

35,000 mg. against a loss of some 27,000 mg. Exactly the same phenomenon occurred in my experiment. It is due to the fact that sodium is the controlling ion, and during deprivation sodium lactate and bicarbonate were lost as well as sodium chloride. During recovery, sodium chloride *only* was returned and the body retained it. In course of time the extra chloride would no doubt have been excreted as the ammonium salt, and the sodium retained and recombined with bicarbonate to restore the original balance.

### The Water Balance

I have already alluded to the difficulty of producing a diuresis during salt deficiency. I now wish to discuss the relation between the loss of sodium and the water balance of the body. I must remind you once again that we all drank as much water as we wanted during these experiments, and our urine volumes were generally over 1500 c.cm. per day. We were therefore not dehydrated in the sense that we were ever deprived of water. Changes in the water balance were due to the loss of sodium, and to

this alone. The importance of securing such experimental conditions has not been generally appreciated, but Kerpel Fronius<sup>8</sup> has recently subjected rabbits to some interesting experiments which were designed to dissociate effects due primarily to loss of water from those due primarily to loss of salt. We did not attempt to measure the intake and output of water, but in these short-term experiments one can take the changes in body-weight as a rough measure of the variations in body water. The Figure shows Niven's loss of weight plotted against his loss of sodium. The two scales are so constructed that a

Subject R. B. N. Loss of weight and sodium.

loss of 1 kg. of body-weight is equal to a loss of 3400 mg. of sodium, which is approximately the amount of sodium in a litre of plasma or extracellular fluid. You will notice that at first each loss of sodium was followed by an almost equivalent loss of weight. During this time there can have been little change in the body's osmotic pressure, although there may have been (and probably was) some anhydræmia and hæmo-concentration. Suddenly the weight ceased to fall. The body had begun to sacrifice its osmotic pressure to maintain its plasma and extracellular fluid volumes. It had been forced into a compromise. It was during this period of compromise, when the osmotic pressure of the plasma was reduced, that we all noticed the abnormality of our water regulation. The fluctuations in Niven's weight are due to this, and one of the most interesting points is the large loss of weight that took place when he began taking salt.<sup>9</sup> I think the abnormal water metabolism of advanced Addison's disease, both clinical and experimental, is due to the loss of salt and the fall in the body's osmotic pressure which has inevitably ensued. In Kerpel Fronius's experiments a primary loss of salt produced changes comparable to those I have described. He also obtained the converse, for he found that a primary loss of water was not followed by an equivalent loss of salt, and that the sodium and the osmotic pressure of the plasma then rose.

### The Blood Changes of Salt Deficiency

We have all shown the same sort of blood changes, some of which are obvious to the naked eye. The venous blood, for instance, becomes sticky and viscous and flows slowly through a needle. The changes in Whitteridge's blood are shown in Table II. The rise in the cell counts, hæmoglobin, cell volumes, and plasma proteins all indicate anhydræmia. The plasma volume was undoubtedly reduced, and the

excretion of urea was certainly not normal. The colloidal osmotic pressure of the plasma was too high, owing to the rise in the plasma proteins, whereas the electrolytic osmotic pressure was too low, owing

TABLE II

Changes in the Blood during Salt Deficiency  
(Subject: D. W.)

	Normal.	Deficient.
Cell count (mil./c.mm.)	4.96	5.95
Hæmoglobin (per cent.)	101	126

K ( " " )	16.2	16.5

to the fall in the serum sodium and chloride. The corpuscle chloride fell, but not the alkali reserve.

You will notice that these are the changes characteristic of experimental Addison's disease which I discussed in my second lecture. I have no doubt that the changes, which were taking place in the tissue cells, were also similar. In one respect only do the present findings differ from those of experimental Addison's disease. It is usual, although I believe not invariable,<sup>1</sup> to find the serum potassium raised in advanced suprarenal insufficiency. We have never observed this, and I feel satisfied that our experimental conditions do not bring about any gross changes in the serum potassium.

### The Nitrogen Balance During Salt Deficiency

I was anxious to make a study of the nitrogen balance because, as I outlined in my second lecture, the existing evidence was so unsatisfactory. The present experiments offered an excellent opportunity of doing so, because the subjects were able to eat ample food and protein to supply the normal needs of the body. Two nitrogen balances have been carried out, one on myself and one on Niven, and both have shown that salt deficiency led to a negative nitrogen balance. As is shown in Table III, my balance

TABLE III

Apparent Nitrogen Balance. From McCance.<sup>9</sup>  
(Subject: R. A. M.)

Deprivation period (days).	Daily intake (g.) (average).	Daily output (g.) (average). <sup>a</sup>	Balance.

4-5 " " ..	17.9	16.3	+1.6

<sup>a</sup> The output includes all sources except blood taken for analytical purposes.

† The last day of the deprivation period was not a full 24 hours. For the construction of this table the actual output for 19 hours has been multiplied by 24/19. The intake for the missing meal has been assumed to be the same as the intake on the previous day.

became more negative as the deficiency grew worse, which suggests an intimate association. Actually the balance was worse than the figures in Table III. suggest, for during the deficiency my blood-urea rose from 30 to 70 mg. per 100 c.cm., and the apparent balance should be corrected for this retention of metabolic products. I have done this by making certain assumptions, and the results are given in

Table IV. I lost 33.6 g. of nitrogen during my deprivation period and 1.6 g. over the five days of my recovery period. The latter was due to the large loss on the first two days when I was still very deficient. If I had been able to carry my recovery

TABLE IV

"Corrected" Nitrogen Balance. (Subject: R. A. M.)

	Deprivation period (11 days).		Recovery period (5 days).

Balance (g.)	-33.6	Balance (g.)	-1.6

period on for a few days longer I would have shown a positive balance over the whole recovery period, as Niven did. Niven lost 45 g. of body nitrogen during his experiment, so that there can be no reasonable doubt that we were in negative nitrogen balance. Just why we were is not quite so clear. It may simply be the result of autolysis of the tissues due to their malnutrition following the reduction in the volume of the blood and interstitial fluids. I imagine that the increase in the viscosity of the blood may also interfere with the normal circulation, and so with the nourishment of the cells. These experimental results undoubtedly have a bearing on the wasting of Addison's disease, particularly the muscular wasting which would probably go on even if there were no digestive disturbances.

The Secretion of Urine

RESPONSE TO AN ALKALOSIS

I pointed out in my previous lecture that clinicians have observed that persistent vomiting may be accompanied by an acid urine. Since protracted vomiting causes an alkalosis, the urine should have been alkaline, and these observations suggest that one of the most characteristic functions of the kidney had failed. The explanations offered to account for this failure have not been altogether satisfactory, and so, since prolonged vomiting causes not only an alkalosis but usually a sodium deficiency as well, I decided to try to reproduce the clinical observations when we were salt-deficient and to study them. We required for this purpose an intense temporary alkalosis which would not interfere with the rest of the experiment. I considered the possibility of producing this by removing hydrochloric acid by a stomach-tube, but I decided that it would be easier and probably more pleasant to remove carbonic acid by overbreathing. The latter has the further advantage of producing a much more violent alkalosis. We have all overbreathed at least twice, once when in normal health and once when salt-deficient. I have done it seven times, and for 45 minutes on each occasion, but I let the others off with 30 minutes and I really think that this is long enough.

The urines secreted before, during, and after the periods of overbreathing were collected and analysed. One untoward incident occurred during these experiments. I foolishly forgot to breathe again voluntarily on one occasion after I had completed my 45 minutes overbreathing. I was so alkaline that I received no stimulus to breathe from my respiratory centre, and the resulting anoxæmia was so sudden and severe that I was unconscious for some minutes and very collapsed for several hours.<sup>8</sup> Miss Widdowson and I are publishing a full account of these overbreathing

experiments.<sup>11</sup> I have simplified and summarised the results in Table V.

You will notice in the first place that the normal response to overbreathing was a diuresis and an alkaline urine. The alkalinity was brought about by

TABLE V

Effect of Overbreathing on the Secretion of Urine

	Normal health. Breathing air.	Salt-deficient. Breathing air.	Salt-deficient. Breathing a CO <sub>2</sub> air mixture.
Reaction of the urine.	Becomes alkaline.	Does not change.	Does not change.

of creatinine	No change.	" "	No change.
of sulphates	"	" "	"
of phosphates	"	" "	"

an increased excretion of sodium and potassium. There was sometimes a small increase in the rate of excretion of chloride as well, but this has no bearing on the present argument. Both sodium and potassium contributed to the increased excretion of base and it was this which brought about the change of reaction to the alkaline side. There was no constant change in the rate of excretion of the other urinary constituents mentioned in Table V.

Now observe what happened when the subjects were salt-deficient. To begin with there was no change of reaction, so you see we have been successful in reproducing the clinical observations. Next you will observe that there was no increased excretion of base. This explains why the urine did not become more alkaline. It is understandable that since the kidney is excreting practically no sodium during salt deficiency, it should not be able to excrete any when the plasma becomes alkaline. I may explain it by saying that the kidney prefers to regulate the osmotic pressure of the plasma rather than its pH, but it is at first most puzzling why the normal increase in the rate of excretion of potassium does not occur. I think the explanation comes from a consideration of the other urinary constituents. Observe firstly that the minute volume fell very greatly instead of rising, and that secondly there was a decrease in the rates of excretion of urea, creatinine, sulphates, and phosphates, whereas there had been no change under normal conditions. In other words, the normal excretory powers of the kidney were seriously curtailed. I think the excretion of potassium was involved in this general depression of functional activity, and hence the normal response was not observed. Now there are two possible explanations for this general depression of activity produced by overbreathing during salt deficiency. The mere muscular exertion of overbreathing might have caused the blood (already greatly reduced in volume) to be diverted from the kidney to the muscles.

On the other hand the depression of activity might have been due to the damaging effect of alkalosis, although why this should only be obvious during salt deficiency is not clear. We have decided between the alternatives by overbreathing during salt deficiency with air mixed with carbon dioxide. In this way we subjected ourselves to the muscular movements, but avoided any alkalosis. The results are given in Table V., and you will see that except for a very slight fall in the rate of excretion of urea there was no other change in the renal activity. We may conclude that the effects observed with air alone were due to the alkalosis.

The kidney therefore must be seriously hampered by an alkalosis combined with sodium deficiency. Now you will recollect that in pyloric obstruction and after persistent vomiting for other reasons, patients have both an alkalosis and a sodium chloride deficiency, and that their urines may be acid. The alkalosis, which should normally provoke the secretion of an alkaline urine, does not do so, because in the first place no sodium is available for excretion, and in the second, the activity of the kidney is so curtailed by the combination of alkalosis and salt deficiency that no extra potassium can be excreted. The high blood-ureas and other signs of renal failure are also due to this combination of salt deficiency and alkalosis. It is interesting in this connexion to recall that steady dosing with alkalis may produce high blood-ureas and signs of uræmia in susceptible persons (see Lecture II.). So far the syndrome has only been incompletely investigated, but I would point out that its resemblance to salt-deficient alkalosis may be purely superficial. Hypochloræmia is common to both, but there is no sodium deficiency when alkalis have been administered, and there are differences also in other respects.

#### GENERAL FUNCTIONAL ACTIVITY

I drew your attention in my previous lecture to the general association between sodium deficiencies and high blood-ureas. I was most anxious to see if the latter could be reproduced under our experimental conditions where there was no water deprivation, for I hoped that, once reproduced, we might be able to explain it. I now realise that a full explanation demands much more work than I have so far been able to do, and I must ask you to regard my results as preliminary rather than final.

Our first attempt to produce a high blood-urea was a failure. Miss Edwards's blood-urea remained quite normal throughout her experiment and so did her urea clearances. The reason I now think was because she ceased to lose more than 0.2 g. of sodium chloride in a 2-hours' sweat and so could not be made really salt-deficient. I next tried on myself. There is no doubt that I become salt-deficient rather easily. The day after my third sweat I found that the urea in my blood had gone up from my normal 30 to 53 mg. per 100 c.cm. On the next day—a Saturday—it had fallen to 46 mg. and I did my last overbreathing experiment in the afternoon. On Sunday morning I drove down alone to the hospital and climbed the stairs to the laboratory, feeling a little breathless and rather miserable. I sat down surrounded by the inevitable litter of food, bottled urines, and reagents lying about the benches. I had done my overbreathes, my blood-urea had gone up; should I stop? Was it in fact wise to go on? I could not make up my mind what to do. Ultimately I came to the conclusion that it would be cowardly to rest content with one blood-urea of 53 mg. per 100 c.cm., so when Miss Widdowson came in I rang up for

other help, and spent the whole of Sunday afternoon sweating. My blood-urea on Monday was 74 mg. per 100 c.cm. and I kept it there till the Wednesday while we completed our observations.

We are accustomed in this country to associate the high blood-ureas of nephritis with an inability to concentrate urea in the urine. I realised very quickly that there was not the usual association in my own case. I knew from preliminary tests and general experience that my kidney could concentrate urea up to a level of about 4 per cent. I continued to be able to do this even when my blood-urea was over 70 mg. per 100 c.cm., and on one occasion found 4.25 per cent. of urea in my urine when my blood-urea was 74 mg./100 c.cm. Subsequently we have found this to be characteristic of sodium deficiency. Niven on one occasion went on hour after hour turning out urine with more than 3 per cent. of urea in it when his blood-urea was 80 mg. per 100 c.cm.

At first therefore I was inclined to regard my high blood-urea as the result of my increased katabolism of body proteins. On the other hand my urea clearances were lower than they had been when the experiment began. I knew, too, from previous experiments with high and low protein diets how much urea I should have been excreting per day for any level of blood-urea up to 70 mg. per 100 c.cm. My actual daily excretions were falling very much short of this. Reconsideration of the matter showed me that my increased N katabolism (34 g. spread over 6-8 days) should not have raised my blood-urea to the height at which it stood when I was salt-deficient. My ability to excrete urea was evidently impaired. There were two reasons for this to be considered.

(1) The anhydræmia with its attendant complications had reduced my glomerular filtration rate. This would have raised the plasma concentrations of all substances excreted solely by the glomeruli. My urine volumes were normal, but I must emphasise once again that a large reduction in glomerular filtration is quite compatible with a normal volume of urine (see Lecture II.).

(2) Additional urea was being reabsorbed in the tubules to regulate the osmotic pressure of the plasma (see Lecture II.).

To decide between these two possibilities the first essential was to obtain a true measure of glomerular filtration rates. I considered the possibility of using glucose after complete phloridzinisation, but I decided it was unsuitable for the present purpose because phloridzin itself seems to affect the filtration,<sup>16</sup> and might have done so to a different extent during salt deficiency. According to Shannon and Smith<sup>17</sup> inulin satisfies all requirements, so I decided to use it. In trying to do so, however, I had a very unpleasant experience which I think I ought to mention. Having got a supply of the purest inulin I could obtain, Mr. E. G. Muir and I injected into a cat rather more than the required dose calculated on the basis of body-weight. The intravenous route was used and the animal seemed none the worse. I next decided to give 1/10th of the standard dose to the man who had volunteered to be made salt-deficient. I did so (intravenously) one day about 11.30 A.M., with no untoward results at the moment, but 10 minutes later the subject began to complain that his hands were cold, and when I looked at him I saw to my horror that they were blue. Five minutes later the man was cyanosed all over and suffering from an agonising headache. I took his blood pressure and found it had risen from his normal 115/75 to 168/110. Presently he began to have a rigor and was sick. His temperature rose in an hour to 103°F. and then over the next hour and a half to 105.2°.

His pulse-rate was 136-140 at this time. At 6.45 P.M. his face was tremendously flushed; his temperature was still 101° F., but he was much more comfortable and he was reading an evening paper. I felt that the worst was over, but during the night his temperature fell to 97° F. and his blood pressure to 65/50. He felt dreadfully ill and his pulse-rate fell to 90 at this time, but rose again next day to 120-130. It was several days before his blood pressure and pulse had returned to their normal levels. He never had any albuminuria, and fortunately he seems none the worse for this unpleasant experience.

After this I decided it would be wiser not to use inulin, so I chose cane sugar instead. It seems that some limited reabsorption of this substance does take place in the tubules, and that therefore glomerular filtration rates determined by cane sugar are too low. They do, however bear a constant relationship to the true rates so that the use of cane sugar is legitimate for comparative purposes. I also decided to determine the creatinine clearances simultaneously, but there were so many other things to do that we have only been able to carry through all these function tests on our last subject. On him we were able to determine the creatinine, cane sugar, and urea clearances when he was normal, and compare them with the same clearances when he was salt-deficient. For this purpose Whitteridge took 6 g. of creatinine by mouth to raise the plasma concentration, and about 30 minutes later we began to give him intravenously 200 c.cm. of a 25 per cent. solution of cane sugar in distilled water. The intravenous infusion occupied half an hour and, commencing about 30 minutes after it was finished, half-hourly collections of urine and blood were made for 2 to 2½ hours. Five experiments of this type were carried out so that in Whitteridge we have been able to determine the three clearances over 24 periods, 15 during normal health, and 9 during salt-deficiency. A summary of the results is given in Table VI.

TABLE VI  
Average Clearances. (Subject: D. W.)

	Creatinine	Sucrose.	Urea.	Urea sucrose.
Normal— Aver. of 15 periods	169 c.cm.	113 c.cm.	76 c.cm.	0.67
NaCl deficient— Aver. of 9 periods	126 ..	78 ..	46 ..	0.59
As percentage of normal .. ..	74	69	61	—

N.B.—The urine volumes were over 2 c.cm./min. in every period.

It will be seen that the normal clearances of cane sugar are lower than those of creatinine. There are two reasons for this. Firstly, the cane sugar clearances are a little lower than the true glomerular filtration rates because some cane sugar is reabsorbed from the tubules. Secondly, the creatinine clearances are a little higher than the true glomerular filtration rates because some creatinine is excreted by the tubules. We may conclude that the true glomerular filtration rate lies somewhere between the cane sugar and the creatinine clearances. The clearances of urea are lower than those of cane sugar and still lower therefore than the true glomerular filtration rates. Hence in all probability some urea is always being reabsorbed.

I take the fall in cane-sugar clearances during salt deficiency to indicate a fall in glomerular filtration rate. There was no change in arterial blood pressure,

and I have so far been unable to convince myself by the cyanide method of any change in circulation rate. I therefore attribute this fall mainly (a) to the decreased blood volume, which probably reduces the number of glomeruli in action; (b) to the increased colloidal osmotic pressure of the plasma brought about by the concentration of plasma proteins. The urea clearances fall rather more than the sugar clearances when the fall is expressed as a percentage of normal. If this difference is significant it means that there has been increased reabsorption of urea. I do not wish to draw any conclusions about this from the present experiments. There may or may not be additional reabsorption of urea. I have still many tests to make on other subjects, not only under the conditions heretofore employed—i.e., large volumes of urine—but also when the volumes of urine are normal or small.

My evidence at present is that the tubule cells are normal. Concentration of urea seems to be unimpaired, and also, so far as I have tested it out, the secretion of ammonia.

### Summary and Conclusion

This, then, is a résumé of our work on sodium chloride deficiency. It is particularly easy to be misled by symptoms, and I feel that I ought to be very much on my guard against drawing hasty conclusions from work of this kind. Nevertheless I feel justified in making one or two comments. In the first place the symptoms and signs of sodium deficiency are strongly suggestive of clinical Addison's disease. There are differences, but I think they can be explained. The low blood pressure, for example, and the pigmentation of Addison's disease may be due to lack of the medullary rather than the cortical hormone. The relative absence of cramps in the clinical disease may be due to its chronic nature, which allows time for the necessary adjustments to be made. In the second place the blood changes are almost identical with those of experimental suprarenalectomy, and when one considers Harrop's recent work, which strongly suggests that the main function of the cortical hormone is to regulate sodium metabolism, then the real significance of the present experiments becomes apparent. I regard them as the link between experimental suprarenalectomy and the clinical disease.

But really they are more. Intestinal obstruction, diarrhoea, and vomiting, and diabetic coma are all diseases in which salt deficiency is a prominent feature. I have great hopes that the present experiments will help us to unravel their respective pathologies, which up till now have appeared so obscure. I feel so hopeful because we have already been able to reproduce experimentally several aspects of these diseases, particularly aspects of renal pathology, and study them under controlled conditions.

I began these lectures by referring to a prophecy of William Prout made in this room over 100 years ago. That prophecy is not yet fulfilled, and can only be fulfilled by more research, but even Prout, visionary though he was, might be surprised if he could see how his subject has already influenced industry, agriculture, and medicine. He would have taken a delight in some of its recent applications to nutrition, bacteriology, embryology, and indeed to almost every field of medical science. A true prophet is seldom the idol of his contemporaries. Physicians of his day subjected Prout to the most scathing criticism for views which seem to us to have been inspired. If I express my confidence in the future

of biochemistry I hope that the physicians of to-day may take a more tolerant view. I feel that the influence of biochemistry on medicine is only in its infancy. I see for example no reason why certain problems of psychology and even of human behaviour should not be solved in the future by intelligent hormone therapy; or why neurology should not become just as biochemical a subject as nutrition. We owe much to surgery and radiology, more so perhaps at present than to biochemistry, but of the three the last is the most fundamental, and the future lies in its hands. Medicine already owes biochemistry a great debt. It will one day be incomparably greater.

The greater part of the original work embodied in these lectures has been financed by the Medical Research Council. I am very grateful to them for this assistance.

## THE DIFFERENTIAL DIAGNOSIS OF DISEASES OF THE COLON

(DYSENTERY AND COLITIS)\*

BY PHILIP MANSON-BAHR, D.S.O., M.D. Camb.,  
F.R.C.P. Lond.

PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES,  
LONDON

(Concluded from p. 765)

THERE are other protozoa which inhabit the intestine of man and may from time to time give rise to dysenteriform attacks.

### Coccidiosis

During the last twenty years various forms of coccidial cysts have been found in the faeces of man, but many of these have been ascertained, mainly by Thomson and Robertson, to be actually parasites of fish, especially of the herring and the sardine, and the cysts are merely passed unchanged through the human intestine when these fish are eaten.

There is, however, one, *Isospora hominis*, which appears to be the genuine inhabitant of the bowel, and more than 150 cases of this infection have been reported in man (Fig. 7). This is not a serious pathogenic entity, although it may produce diarrhoea

and distressing symptoms. The cysts of the parasite are easily discovered in the faeces, and their further development can be demonstrated by placing them for several days in an incubator. In those cases which I have personally observed, the faeces contained pus cells and Charcot-Leyden crystals. Most of the infections come from the Eastern Mediterranean, but cases from the West Indies have also been recorded. The infection does not seem to be very prolonged, and symptoms subside without any particular treatment.

### Giardiasis

A more complicated problem is presented when the bowel is infected with the protozoal flagellate, *Giardia (Lambia) intestinalis*. This parasite, which is provided with a sucking disc, attaches itself to the mucous membrane of the small intestine and apparently feeds upon the mucous surface without actually invading the bowel wall of man, although similar species are found in rats and mice, cats and dogs, in which definite intestinal lesions are observed. The parasite has a further historical interest in so far that it is the first protozoon ever seen by man, when it was discovered by Leeuwenhoek in 1681 with his primitive microscope. Interest has been aroused in recent years by the discovery of large numbers of these flagellates in the duodenal juice removed by means of a duodenal tube, and also in the bile obtained at operation. Encysted forms which may be confused with those of *Entamoeba histolytica* are commonly found in the stools of infected persons. This parasite is common and widely distributed in all parts of the tropics, but is also seen occasionally in children in this country.

A great diversity of opinion manifests itself at different times, and in different countries, towards the pathogenic rôle of this parasite. I am of the opinion that under certain conditions giardia is distinctly pathogenic, and that its numbers depend upon the diet of the individual infected. The mass infection of the small intestine appears to produce an irritative lienteric form of diarrhoea. The stools are pale, large, and contain undigested residue. The symptoms of giardiasis are somewhat indefinite, but consist of an explosive diarrhoea with flatulency and abdominal discomfort; sometimes a quantity of mucus is passed with the faeces.

The diagnosis is interesting in view of the need of its differentiation from sprue. The parasites are easily discovered in the faeces; in the acute stages the active flagellated parasite is found, and in the more chronic ones, the characteristic cysts. The main methods of treatment consist in altering the dietary of the patient and substituting a purely protein for a carbohydrate diet.

### Flagellate Diarrhoea

Various other forms of protozoal flagellates are found abundantly in diarrhoeic faeces of man, and it has been a matter of considerable perplexity to ascertain the part played by these minute organisms. The two main forms are known as trichomonas and chilomastix. The presence of these flagellates in the stools and in the intestine is certainly indicative of a contamination of the food taken in by the mouth, but it is thought by most people that their presence, often in enormous numbers in diarrhoeic faeces, is due to their capacity to multiply in such a suitable medium; they are, in fact, the outcome and not the cause of the diarrhoea.

They may be therefore a superadded infection on top of amoebic or bacillary dysentery. The matter is still unsettled.

\* The Lettsomian lectures for 1936 delivered before the Medical Society of London on Feb. 17th and 26th and March 2nd,

FIG. 7.—Intestinal coccidiosis. Case from the West Indies, showing appearance of feces under the microscope and cysts of *Isospora hominis* and also Charcot-Leyden crystals.

One cogent reason in the minds of those who maintain that these flagellates may be the cause of a peculiar diarrhoea is that, after appropriate treatment such as colonic lavage, the active forms disappear from the faeces and the active symptoms tend to subside.

#### Malarial Dysentery

Dysenteric symptoms are occasionally associated with protozoal blood disease. In the most severe forms of malarial infection produced by the subtertian malaria parasite (*Plasmodium falciparum*), dysenteric symptoms are occasionally observed. This is the so-called malarial dysentery of which I saw many examples during the Great War. Very often it is true the dysenteric syndrome is brought about by a superadded infection with the dysentery bacillus, or the dysentery amoeba, but there certainly exists a residuum of cases in which no active dysenteric agent can be discovered. The underlying pathology of this condition is due to the massive blocking of the smaller blood-vessels of the mucous membrane of the large intestine with sporulating subtertian parasites, after which actual hæmorrhages take place (Fig. 8).

The appearance of the stools therefore in these cases is not unlike that of hæmorrhagic colitis. Of course, the diagnosis is easily made by the discovery of the malarial parasite in the blood, and sometimes I have succeeded in demonstrating them in the red blood corpuscles which appear in the stool; all of which goes to show how very numerous these parasites must be.

#### Leishmanial Dysentery

Leishmanial dysentery is found in visceral leishmaniasis or kala-azar. In the terminal stages of this infection a massive invasion of the villi of the small intestine, and of the crypts of Lieberkühn of the large intestine with the Leishman-Donovan bodies occurs, leading to the actual ulceration of the bowel (Fig. 9). This in turn leads to the passage of blood and mucus in the stools in which the Leishman-Donovan bodies have in fact been demon-

strated. Naturally these cases are very rare and are only encountered in Assam, the endemic centre of the disease. In these cases other signs and symptoms of kala-azar are sufficiently obvious.

### The Colitis Group

#### MUCOUS COLITIS

It is necessary to state that I disagree with those who deny the separate existence of a pathological condition of the colon which produces the sequence of symptoms usually known as "mucous colitis." The aetiology of this condition has been the subject of much debate; but it is agreed by those who investigate their cases thoroughly that mucous colitis is a definite entity.

Perhaps it is best to look upon it as an allergic condition of the mucous membrane of the bowel which is associated with a distinct neurological element. It is a matter of observation that these patients are of a distinctive introspective type, and their interest in living is mainly centred in their digestive tract. In tropical practice the symptoms of mucous colitis are a common sequel to one or other of the classical forms of dysentery, and it is very often difficult to ascertain where the symptoms of dysentery end and those of mucous colitis begin.

Associated with the discharge of large quantities of mucus and undigested food remains from the bowel there is a spastic condition of the colon which can be demonstrated by a barium enema. I consider that the stools of mucous colitis are quite distinctive and the condition can be diagnosed by microscopical examination.

The nuclei of the mucous cells as seen in the stool resemble those of the goblet or mucus-secreting cells of the large intestine, and can be easily recognised (Fig. 10). A search for distinctive micro-organisms in the stools of these cases usually leads to a false clue. Naturally all kinds of micro-organisms, and

FIG. 8.—Malarial "dysentery." Section showing sporulating forms of the subtertian parasite (*P. falciparum*) blocking the capillary vessels.

especially streptococci, may be isolated; but there is no proof that they are the actual cause of this condition. The sigmoidoscope is of considerable value in making a positive diagnosis. The mucous membrane is of a pale, rather yellow appearance, and is coated with ropes of viscid mucus. The surface of the mucous membrane itself is dry and unhealthy (Fig. G on Plate published last week).

Everybody knows that these cases are very difficult to treat successfully. The main principle appears to be to put the bowel at rest as much as possible by the injection of bland substances, such as olive oil, and at the same time allay the nervous apprehensions of the patient.

#### ULCERATIVE COLITIS

There are very many great difficulties in discussing this difficult subject, as our premises do not rest upon definitely formed grounds. In fact the term "ulcerative" is not strictly correct in describing this condition. From the observations that have been made in a series of cases in the Hospital for Tropical Diseases, the initial lesions in the mucous membrane of the bowel seem to be a large number of small hæmorrhages, and this stage is followed (as observed by sigmoidoscopy) by a peculiar plush-like congestion of the mucosa. Next a layer of granulation tissue forms on the mucous surface which is extremely friable and is easily traumatised by the discharge over it of faecal matter. Actual ulceration of the mucosa is a late phenomenon and is only found in the terminal stages of the disease when secondary infection has taken place (Figs. H, I, J, K on Plate).

The whole natural history of this disease marks it out definitely as a specific infection, but it is certain that the true ætiological factor remains to be discovered. So far a search for the true cause in the flora of the intestinal tract has proved to be a wild-goose chase. The association of pyrexia, of toxæmia, of arthritis, as well as all other metastatic phenomena, accompanied by grave anæmia and definite blood changes, seems to indicate that in ulcerative colitis we are dealing with a systemic blood dyscrasia in which the toxic elements are being excreted via the

FIG. 10.—Mucous colitis. Fæces preparation of mucous colitis case showing the type of mucus-secreting cell in the stools.

mucous membrane of the large intestine, and so are producing the train of symptoms just described.

There is no certain way of diagnosing ulcerative colitis, save by the general clinical picture, backed by sigmoidoscopic examination. The stools themselves resemble closely those of the chronic stage of bacillary dysentery, and it cannot be said that on microscopical examination they present any distinctive features. The predominating cell is the polymorphonuclear leucocyte, while Charcot-Leyden crystals are common and large phagocytic macrophage cells are seen (Fig. 11).

#### MEMBRANOUS COLITIS

Membranous colitis resembles the former condition very closely, except that from time to time casts—which may be almost complete—of the mucous membrane of the large intestine appear in the stools. There appears to be no essential difference in the exudate from that of the ulcerative form, save that from time to time portions of mucous membrane with the characteristic columnar epithelium can be recognised.

I regard the ætiology of this condition as being in the main similar to that of the ulcerative form.

It cannot be said that there are any characteristic appearances of the mucous membrane as seen through the sigmoidoscope, at least in those cases I have investigated. Usually the area of the exfoliating membrane is in the upper part of the large intestine, far removed from the field of vision of the sigmoidoscope.

Unfortunately in this form of colitis, as indeed in the other varieties already considered,

FIG. 9.—Kala-azar "dysentery." I. Section of Lieberkühn's follicle showing infection of columnar cells with leishmania. II. Leishmania bodies as they appear in smear preparations. III. Leishmania bodies enclosed in endothelial cells.

there is a distinct neuropathic factor. Membranous colitis usually supervenes in a peculiar type of introspective hyperneurotic persons, usually of the female sex.

#### COLITIS PRODUCED BY FOREIGN BODIES

An irritative form of colitis may be brought about by the impaction of any foreign body in the rectum. Thus such a foreign body may consist of pig's bristles, fish-bones, or even (as in one case in my experience) portions of a glass tumbler inserted into the rectum. There is usually little difficulty in making a diagnosis in this condition.

#### TOXIC COLITIS

*Mercurial poisoning.*—Toxic colitis, resembling in its clinical aspects a severe ulcerative colitis, has been described in chronic mercurial poisoning in industrial workers, and is always associated with chronic nephritis. It is usually fatal. I have been unable to find any more information on this subject than can be gleaned from books on pharmacology.

*Food-poisoning.*—In certain cases of infection by paratyphoid B, and other members of the salmonella group, ulceration of the large intestine may occur, giving rise to the appearance of blood and mucus in the stools, from which the specific bacillus can be isolated. These cases are admittedly rare, and I have not seen any instances of this nature since the epidemic of paratyphoid fever in Gallipoli in 1915.

*Uræmic colitis.*—Acute inflammation of the mucous membrane of the large intestine with blood and mucus in the stools is not infrequently seen in the terminal stages of uræmic poisoning. The colitis is undoubtedly caused by the excretion of toxic substances through the bowel wall.

#### Miscellaneous Group

##### TUBERCULOUS INFECTION OF THE COLON

It is commonly stated in text-books on medicine that tubercle of the large bowel in adults is of great rarity, but in my experience tuberculous lesions of the bowel wall itself, or ulceration of the mucous membrane, are not uncommon in residents in the tropics. The tuberculous infiltration of the large intestine may be confined to the cæcum, as in a well-known hypertrophic form, or may affect other portions of the large intestine.

Tuberculous ulceration can be recognised during sigmoidoscopy, and the tubercle bacilli can be demonstrated in material taken from the ulcers through the sigmoidoscope (Fig. L on Plate). It is always advisable to search for these acid-fast organisms in cases of chronic diarrhoea which cannot be diagnosed by other means. As the result of considerable experience on this subject, I hold that it is not possible to exclude tuberculosis of the bowel on a single examination of the stool. The bacilli appear in the fæces in showers and can be demonstrated very often after washing out the bowel with saline enemata.

Possibly the comparative frequency of this infection in tropical residents may be due to the lowering of the resistance of the mucous membrane by previous dysenteric infection. At any rate the cases that I have diagnosed occurred in dysenteric subjects. The stools may contain blood and mucus from time to time and on microscopic examination may consist of pus and other inflammatory cells.

##### SYPHILITIC DISEASES OF THE BOWEL

Syphilitic stricture of the rectum associated with the ulceration of the mucous surface is one of the rarities of medicine, and I am convinced that many

of the so-called syphilitic lesions of the large intestine can be more satisfactorily explained on other grounds. I have seen only one case which was diagnosed by sigmoidoscopy, and in which the Wassermann reaction was positive. The condition eventually responded to specific treatment. Blood and mucus may be passed also.

#### LYMPHOGRANULOMA INGUINALE

Lymphogranuloma inguinale is a condition which parades itself under a variety of names and was formally known as climatic bubo. Quite recently Stannus has drawn attention to the fact that the *genito-*

FIG. 11.—Acute ulcerative colitis. Cellular exudate showing clumps of red cells, macrophage cells, and Charcot-Leyden crystals.

*ano-rectal syndrome*, which is so frequently seen in native women especially in China, may be explained on the climatic bubo basis. The virus of this disease is ultramicroscopic and affects the lymphatic glands; travelling via the lymph-flow it may reach the rectum and cause chronic inflammation and stricture. The proof that such a stricture is due to this infection can be ascertained by the intradermal test; for instance, in 1932 Frei reported that 80 per cent. of these cases gave a positive intradermal test. Rectal stricture may lead to ulceration, and in 1934 I had a case of this kind under my care of 17 years' duration, in which the patient was passing blood and mucus stools resembling those of dysentery.

#### MALIGNANT DISEASES AND POLYPOSIS

These two conditions are grouped together because of the similarity of their symptoms, and of their very serious and usually fatal character. Malignant ulceration of the bowel must always be borne in mind, especially in elderly people of either sex. The discharge of blood and mucus from the rectum may be the first and possibly the only sign of a malignant growth situated somewhere in the large intestine. As a rule, the more profuse the dysenteric symptoms the higher in the bowel is the growth situated.

Malignant changes not infrequently take place, as Willmore has shown, at the base of chronic amoebic ulcers. The practitioner in the tropics therefore should not content himself with merely inspecting

the stools of every dysenteric-like case, but should perform a rectal or sigmoidoscopic examination in every instance where a true dysenteric infection cannot be ascertained. The stools contain pus cells, epithelial cells, and often Charcot-Leyden crystals (Fig. 12).

As regards *polyposis*, there is no doubt that this is a hereditary affection of the colon. The symptoms may be those of a dysentery, but usually there is a profuse hæmorrhage together with blood and mucus. I have encountered three instances of this disease which could be diagnosed easily by sigmoidoscopic examination. Death always occurs through the

FIG. 12.—Carcinoma of rectum. Cellular exudate of case of rectal carcinoma with intestinal epithelium and Charcot-Leyden crystals, from a case which had been treated as amœbic dysentery for 1½ years.

supervention of malignant changes. (A pseudo-polypoid condition can be a sequel to chronic ulcerative colitis and to chronic bacillary dysentery. Lockhart-Mummery recognises an adenomatous form.)

#### DIVERTICULITIS

It is a matter of considerable surprise to find that blood and mucus may be passed in cases of diverticulitis, and this is probably due to the ulceration of the mucous membrane which may accompany advanced stages of this disease. I have seen several instances of patients who have been sent from the tropics labelled "incurable amœbic dysentery."

Of course these cases can be easily diagnosed by means of a barium enema, but I have not had much success in gaining further information from the sigmoidoscopic examination. It cannot be said that there is anything distinctive about the stools, which may closely resemble those of amœbic dysentery.

#### POLYPUS : INTUSSUSCEPTION : HÆMORRHOIDS

*Simple polyposis*.—Simple polyposis of the rectum or of the large intestine may give rise to dysenteric symptoms. From time to time people have been referred to me from the tropics, perhaps children who have been thought to be intractable cases of dysentery, and in one instance a man of 64 years of age. But the suspicion regarding the possibility of this diagnosis should be engendered if the general condition of the

patient is good, and there is no loss of weight. As a rule there is a considerable amount of pain on discharge of the stools associated with polypus, and from time to time a not inconsiderable hæmorrhage. The stools usually contain glairy masses of mucus tinged with blood resembling sputum and passed apart from the fæces themselves. Naturally the diagnosis can be clinched by sigmoidoscopy, and occasionally by means of a barium enema; but this is usually not quite so easy.

*Intussusception*.—Intussusception is associated with the discharge of bright red blood and mucus in the stools. This may be an accident supervening upon bacillary dysentery or may arise from other causes. It is usually found in infants and small children, and the other appearances are quite characteristic. It is mentioned here for the sake of completeness.

*Internal hæmorrhoids*.—Internal piles, especially when they are thrombosed or have become infected, may give rise to the passage of blood-stained mucus. The diagnosis is easily made by the employment of the proctoscope. Sometimes, too, a small degree of ulceration may actually be present.

## NEURITIS IN PREGNANCY SUCCESSFULLY TREATED WITH VITAMIN B<sub>1</sub>

By G. W. THEOBALD, M.D. Camb., M.R.C.P. Lond.,  
F.R.C.S. Edin., F.C.O.G.

FIRST ASSISTANT TO THE DEPARTMENT OF OBSTETRICS AND GYNÆCOLOGY, THE BRITISH POSTGRADUATE MEDICAL SCHOOL, HAMMERSMITH; CONSULTING GYNÆCOLOGIST TO THE NORTH KENSINGTON WOMEN'S WELFARE CENTRE; LATE ASSISTANT MASTER, THE ROTUNDA HOSPITAL, DUBLIN

(From the Hammersmith Hospital and St. Mary Abbots Hospital)

It has long been recognised that neuritis may be associated with pregnancy, and although it has been suggested that the pregnancy may lower the resistance of the body to some toxin—e.g., from a septic tooth—which causes the neuritis, the view generally held is that the condition is a manifestation of a pregnancy toxæmia, the result of a toxin peculiar to pregnancy. The fact that the polyneuritis of pregnancy in its severer form is usually associated with hyperemesis gravidarum has been considered to lend support to the latter assumption.

The symptomatology of the condition is well known; it may progress until Korsakoff's syndrome is manifested. Many of these patients die and at autopsy not only changes in the peripheral nerves but also degenerative changes in the anterior horn cells and petechial hæmorrhages in the brain and spinal cord have been described (Berkwitz and Lufkin, 1932; Luikart, 1933; Ford, 1935). It is thus evident that patients dying from beri-beri, scurvy, and the polyneuritis of pregnancy may show similar histological changes in the tissues of the nervous system.

In 1930 I suggested that the cases of pregnancy neuritis seen in this country might be a form of beri-beri, and for three reasons: (1) the incidence of the neuritic form of beri-beri in Bangkok was much higher in pregnant than in non-pregnant women, indicating that an increased intake of vitamin B was necessary during pregnancy; (2) the neuritic

symptoms of beri-beri were indistinguishable from those of the polyneuritis of pregnancy; and (3) I was of the opinion that all the toxæmias of pregnancy were interrelated and due to dietetic deficiencies and considered that the increased incidence of beri-beri during pregnancy supported that hypothesis. Curiously enough in the same year and the same month Wechsler, from the neurologist's viewpoint, drew attention to the probable occurrence of deficiency polyneuritis in hitherto unsuspected cases, including those associated with pregnancy. Three years later Strauss and McDonald reported the results of the dietetic treatment of three cases in which pregnancy polyneuritis was associated with anæmia and hyperemesis gravidarum. Two of the patients were delivered before the treatment was commenced, but in the third a very marked improvement occurred and the patient was delivered at term by Cæsarean section. In addition to a high protein diet the patients were given considerable amounts of vitamins A, B<sub>1</sub>, B<sub>2</sub>, and D, and of iron. In the same year (1933) I reported, in a general paper on the toxæmias of pregnancy, a case of pregnancy polyneuritis cured by dietetic measures. This patient early in pregnancy suffered from a polyneuritis affecting all four limbs. Both knee-jerks were absent. There was wasting of the thenar and hypothenar eminences and general tenderness on deep muscle pressure. The hand grip was very weak on the right side. In addition the patient evinced choreiform movements of her limbs and head. She was put on an adequate diet rich in vitamins A, B, C, and D and was indistinguishable from a normal person when she came to be confined. Fouts, Gustafson, and Zervas (1934) and others have reported further cases of pregnancy polyneuritis successfully treated by diet.

Apart from these cases, which are uncommon, every obstetrician of experience has treated patients complaining of tingling and numbness particularly affecting the fingers and usually associated with a gnawing pain which runs up the arm, particularly at night. This pain, which disturbs sleep, usually demands the exhibition of hypnotic drugs and the condition rarely, if ever, clears up before delivery. I have seen a number of such cases, particularly in Leeds, and have recently been told by post-graduates from South Africa, Australia, and India, that they have observed the condition not infrequently, that they have never seen it clear up before delivery, and that the pain invariably demanded the administration of some drug.

The purpose of this paper is to report the successful treatment of 5 such cases by dietetic measures, in 4 of them solely by the administration of vitamin-B<sub>1</sub> concentrate. All the patients complained of numbness, tingling, pins-and-needles, and, with the exception of Case 5, of pain which was worse by night. The arms and hands were affected in all the cases, and one side more than the other.

#### THE FIVE CASES

CASE 1.—A primigravida, aged 26, first complained at the antenatal clinic of tingling of the fingers on Sept. 5th 1935, and was given calcium and Advita\* capsules (four daily) to take home with her. A week later the symptoms were worse and she was admitted to St. Mary Abbots Hospital on Sept. 15th. She complained of pins-and-needles and numbness in the fingers of both hands and pain shooting up the arms, particularly affecting the left side. The pain was severe and wakened her

up several times in the night, but did not disturb her much by day, although the numbness and pins-and-needles persisted. She was put on the full antenatal diet already described (Theobald, 1935) and was given in addition to vitamins A, B, and D, daily intravenous injections of 10 c.cm. of a 10 per cent. solution of calcium gluconate. Her condition improved so rapidly that she was discharged on Sept. 21st, complaining merely of tingling and numbness in her fingers. She was given calcium tablets and advita capsules to take out with her and came up three times in the week for intravenous calcium injections. Her condition rapidly disimproved and the pain recurred waking her up frequently, and making sleep impossible after 5 A.M. She was then given Bemax† in addition to other substances to take home with her and a few days later her symptoms improved and she slept better. She was again admitted to hospital on Dec. 6th by which time the right hand was normal. The fingers showed normal sensation to heat, cold, pinpricks, and cotton-wool. The tendon-jerks were more difficult to elicit on the left than on the right side, the biceps-jerk not being obtained. Her symptoms rapidly cleared up on the full diet and it is unfortunate that she was not seen by a neurologist until all her symptoms had disappeared. On Nov. 15th Dr. D. H. Brinton reported that there was no evidence of any organic nervous disease except for inequality of biceps-jerks. He thought, however, that the history of paresthesia was very suggestive of an early peripheral neuritis. Except for slight tingling which occurred on three subsequent occasions, one being the day after delivery, the patient had no further symptoms during her stay in hospital.

Two days after she left hospital, however, pain, numbness, and tingling recurred in her left arm, the right remaining normal. At her visit to the postnatal clinic a month later she reported that the condition in her left arm had been getting progressively worse so that it was then as bad as it had ever been. Tingling in the fingers occurred at intervals during the day, but at night the old pain shot up her arm leaving it numb and powerless, so that she could not hold the suckling baby with it. She was given vitamin B<sub>1</sub>‡ tablets in dosage of 2250 units daily. Within three days the pain and numbness ceased to affect her arm, and at the end of the week she complained merely of occasional tingling in the fingers of the left hand. After a further fortnight on this dosage of vitamin B<sub>1</sub> her symptoms entirely disappeared.

In this case the successful treatment before delivery showed the symptoms to be due to dietetic deficiency, while that subsequent to her confinement proved them to be due to a deficiency of vitamin B<sub>1</sub> in her diet.

CASE 2.—The patient, a 2-gravida aged 33, complained on Nov. 5th, 1935, of pain in her right arm and leg which had troubled her for about three weeks. It did not bother her by day, but at night the pain was so severe that she walked round the room "the whole night." She said she had not had a decent night's rest for the last three weeks. The pain ran up the arm and down the right side to the leg and was associated with marked numbness and tingling of the toes and fingers. The tingling (pins-and-needles) occurred by day. Sensation was unimpaired, the tendon-jerks were normal, and the knee-jerks brisk. There was tenderness on deep muscle palpation and slight pressure along the nerve trunks of the right arm and leg elicited pins-and-needles in the fingers and toes. Similar pressure applied to the left limbs had no effect.

She was sent home and given B<sub>1</sub> tablets (10 = 1500 units) daily; no further change of any kind was made in her dietary. On Nov. 12th she reported that she had three fairly good nights during the previous week; she thought her condition was improving. On the 19th she was "much better." The right leg was normal, and she had had one day with no tingling or numbness in her right hand. On the 26th she stated that she had had no

† One ounce (or 4 heaped tablespoonfuls) of Bemax contains 400 units of vitamin B<sub>1</sub>.

‡ Each of these tablets prepared by Messrs. Vitamins Ltd. weighs 0.75 g. and contains 150 units of vitamin B<sub>1</sub> and no other active substance.

\* Each capsule contains 111 of concentrated whale oil, in 1.0 gramme of which there are 25,000 units of vitamin A and 1000 units of vitamin D.

abnormal sensations in either of the affected limbs for some days.

There was no recurrence of symptoms either before or after delivery.

CASE 3.—On Sept. 16th, 1935, the patient, a 5-gravida aged 39, complained of severe cramps in her calves, insomnia, and tingling (pins-and-needles) in the fingers of the left hand. She was given an intravenous injection of 10 c.cm. of calcium gluconate and calcium and advita capsules to take home with her. (Calcium grs. 20; vitamin A 10,000 units, vitamin D 400 units, daily.) On Oct. 15th she reported that the cramps had ceased and the insomnia was better, but she was awakened several times in the night by gnawing pains down the arms to the hands, accompanied by numbness and tingling in the fingers. The left hand was much worse than the right. The circulation of the left arm was cut off for five minutes by means of an armlet. The fingers did not flex and she was able to maintain them fully extended without much discomfort.

On Oct. 22nd she said that for the last 14 days the condition of the left hand had been getting worse, so that she could no longer dress her children. In the morning the fingers were partly flexed and she was unable to extend them. They "cramp up" and are "dead." She complained of numbness, tingling, and loss of power in the left hand, the tingling and numbness persisting throughout the day. There was hypersensitivity along the course of the ulnar nerve. She had been seen on the previous day (Oct. 21st) by Dr. J. Purdon Martin who reported as follows: "Tendon-jerks all very brisk. Marked bilateral finger flexion. No sensory disturbance. Right plantar response flexor; left indefinite. In view of the increased tendon-jerks, spinal cause for the pains is suggested."

The calcium and vitamin capsules were discontinued and she was given vitamin B<sub>1</sub> tablets to take home with her and told to take ten daily. By Oct. 25th the condition had definitely improved, and she could dress her baby. On the 29th she said that she had the tingling sensation and numbness in her fingers only in the morning. On Nov. 12th the hand was quite normal and she had done a good day's washing on the previous day.

The vitamin B<sub>1</sub> tablets were discontinued, and the symptoms did not recur either before or after delivery. It will be observed that this patient also suffered from a deficiency of vitamin D in her diet.

CASE 4.—A primigravida, aged 23, 38 weeks pregnant, complained of tingling and numbness in both hands, but particularly the right hand, of a week's duration. The "pins-and-needles" ran all the way up the arm and once she had what she described as an "electric shock" at the tips of her fingers. The pain wakened her up three or four times in the night. She was given vitamin B<sub>1</sub> tablets, 2250 units daily, and the symptoms cleared up completely within ten days; neither did they recur after delivery.

CASE 5.—On Oct. 23rd, 1935, a primigravida, aged 25, complained of cramps in legs and hands, insomnia, and tingling and numbness of both middle fingers by night and by day. It had become very unpleasant for her to touch wool or silk with these fingers. On the 26th she was admitted to the antenatal ward and given the routine diet, but no bemax. Five days later there was no improvement in the fingers, and she was put on 15 vitamin B<sub>1</sub> tablets daily, all other substances additional to the basal diet being discontinued. On Nov. 9th no significant improvement was apparent. Both index-fingers were now slightly affected. The full routine diet was therefore commenced, the bemax being increased to 3iss. daily and advita capsules from 4 to 20 daily. On the 16th the condition was improving, but pins-and-needles developed in both arms on the 21st and persisted for five days. By Dec. 4th sensation in the affected fingers had been normal, except on deep pressure, for three or four days.

The symptoms did not recur. After the first two nights in hospital she slept well, had no cramps, and the oedema, except for the degree which was present apart from pregnancy, disappeared.

This patient was seen by Dr. Macdonald Critchley, who diagnosed the condition as gestational neuritis. Her neuritic symptoms were the least conspicuous of any of the five patients, and yet it took over six weeks to effect a cure. Apart from the rich diet she received vitamin A 50,000 units, vitamin D 2000 units, and vitamin B<sub>1</sub> 2850 units daily. It can be asserted that the condition responded to dietetic treatment, but it is not possible to say whether it was due merely to vitamin-B<sub>1</sub> deficiency in the diet. It must be presumed that the few fibres involved had suffered degenerative changes necessitating time for repair after the deficiency in the diet had been made good. It will be noted that this patient also suffered from the effects of a deficiency of vitamin D in her dietary.

#### DISCUSSION

It is immaterial whether the well-recognised syndrome exhibited by these patients is to be attributed to a peripheral neuritis, as is commonly taught, or to lesions in the spinal cord. It is, however, important to distinguish between the tingling sensations due to nervous lesions and those believed to be occasioned by circulatory disturbances. In the latter cases the pins-and-needles occur symmetrically in both hands, as frequently by day as by night and disappear when the fingers are rubbed together or the hands allowed to hang down for a few minutes. In between the attacks the fingers feel quite normal. If the circulation be cut off by an armlet applied to the arm the fingers tingle immediately and after a lapse of about three minutes they become partially flexed, the patient being unable to maintain them in the extended position. In those cases where the symptom first appears towards the end of pregnancy the condition can usually be cured within a few days by calcium therapy.

It must remain an open question as to whether the cases I have reported represent an early stage of the severer form of pregnancy polyneuritis for which Berkwitz and Lufkin have suggested the term "toxic neuronitis." It is interesting on the one hand to note that Strauss and McDonald and others have caused much improvement in such cases by dietetic measures, and on the other to recognise that the symptoms of Cases 2 and 3 might be considered to have been due to lesions in the spinal cord.

Reference has already been made to the statements of Berkwitz and Lufkin and of Luikart that the histological changes in the nervous system are similar in beri-beri, pellagra, scurvy, and the polyneuritis of pregnancy, or in other words presumably, that severe deficiency of either vitamins B<sub>1</sub>, B<sub>2</sub>, or C in the diet may lead to degenerative changes in the anterior horn cells.

The position is still further complicated by the fact that lesions both in the spinal cord and in the peripheral nerves may occur in animals fed on a diet rich in the vitamin-B complex and that these lesions may be prevented by the addition of vitamin A to the diet (Hart, Miller, and McCollum, 1916; Hughes, Lionhardt, and Abel, 1929; Mellanby, 1929). Beri-beri is usually attributed to a deficiency of vitamin B<sub>1</sub> in the dietary, but Mellanby (1934) suggests that the nerve lesions associated with this disease as well as those occurring in pellagra and lathyrism are due to vitamin-A deficiency. He asserts that he is unaware of any evidence which proves that neuritis involving demyelination of nerve-fibres can be produced in animals by diets deficient only in the antineuritic vitamin B and doubts whether the condition once produced can

be cured by the exhibition of this vitamin alone. The apparently conflicting laboratory results appear to be due to two main facts: (1) in order to produce lesions in animals it is often necessary to feed them with diets to which they are not accustomed and which may be deficient in other substances, organic and inorganic, as well as the vitamin concerned; (2) once nerve lesions have been produced a long period of time may be necessary for their recovery even when the diet is adequate, and it is difficult, if not impossible, to be sure of early lesions in animals.

The main reason why this question has been discussed in some detail is to draw attention to the remarkable opportunities afforded by pregnancy to study with the precision of laboratory experiments the early stages of vitamin deficiencies as they occur in man. Thus insomnia, headache, muscular cramps, vomiting, skin rashes, and circulatory disturbances including dizziness and tingling of the fingers may undoubtedly be caused by disturbance of the calcium metabolism. The gingivitis of pregnancy is probably due to vitamin-C deficiency in the diet, and offers the opportunity of investigating the possibility of masked vitamin-C deficiency occurring during pregnancy apart from the scurvy symptom-complex. It is indeed probable that the uncomplicated effects of any vitamin deficiency in the diet can only be observed in the early stages of its operation. Gross deficiency of any vitamin in the dietary may result in lesions not merely due to deficiency of that vitamin but to a resultant disturbance of the metabolism, the factors concerned being as yet imponderable. The interrelation between and the interactivity of the vitamins are little understood, but the harmonious interdependence of the hormones may provide an analogy.

It has been reported that symptoms due to nervous lesions and occurring towards the end of pregnancy were cured, usually within three weeks, merely by the addition of from 1500 to 2250 units of vitamin B<sub>1</sub> to the daily diet, without otherwise altering it or changing the environment of the patient. In two of these patients the symptoms progressed in spite of the daily addition of vitamin A (10,000 units) and D (400 units) and calcium lactate, grs. 30, to their basal diets. It is, moreover, of interest to note that at least two of these patients suffered from a deficiency of vitamin D in their dietaries.

Inasmuch as it was postulated that the neuritis as well as all the "toxæmias of pregnancy" were due to deficiencies in the diet and inasmuch as the neuritis of pregnancy has been attributed to the toxin of pregnancy—to that extent the results now reported may be held to support the dietetic-deficiency hypothesis of the toxæmias of pregnancy. The form of neuritis described is, I consider, best termed "atelo-sitetic neuritis of pregnancy"—a term derived from the Greek *ἀτελής* (imperfect) and *στροφή* (nutrition).

#### SUMMARY

1. Five patients, in the later weeks of pregnancy, suffering from a symptom-complex due to nervous lesions and usually described as gestational neuritis were cured by dietetic treatment.

2. In four of these patients the symptoms were completely relieved merely by the addition of vitamin B<sub>1</sub> to their dietaries. It may therefore be assumed that the symptoms resulted from a deficiency of that substance in the diets.

3. Two of these patients suffered in addition from deficiency of vitamin D in their diets.

4. It is at present impossible to say whether these symptoms represent an early stage of the "toxic neuronitis" of pregnancy.

5. Pregnancy offers opportunities for studying the effects of vitamin and other deficiencies in the diet with the precision of a laboratory experiment.

6. The results reported may be held to support the dietetic-deficiency hypothesis of the toxæmias of pregnancy.

I wish, in conclusion, to thank Prof. James Young for allowing me to undertake the treatment of these patients who were admitted either to the Hammersmith Hospital or to St. Mary Abbots Hospital, and Mr. J. Carver, medical superintendent of the latter hospital, for his unfailing coöperation. I have pleasure, moreover, in expressing my indebtedness to Sir Frederick Menzies, medical officer of health for the county of London, for permission to publish data concerning patients admitted to St. Mary Abbots Hospital.

#### NOTE ON

### MALE HORMONES AND THE QUESTION OF ACCESSORY SUBSTANCES

BY R. DEANESLY, D.Sc.

AND

A. S. PARKES, Sc.D., F.R.S.

(From the National Institute for Medical Research, London)

IN making the original announcement of the isolation of testosterone from the testis, Laqueur and his collaborators<sup>1</sup> reported that its male hormone activity was greatly increased by the addition of an  $\alpha$ -substance, itself inert, obtainable from testis. These authors found further that androstanediol could be similarly activated,<sup>2</sup> and that the  $\alpha$ -substance was probably of the nature of a fatty acid and occurred in various tissues and body fluids.<sup>3</sup>

These results have been confirmed and extended by workers in Basle (see Ruzicka, Wettstein, and Kägi<sup>4</sup> and Miescher, Wettstein, and Tschopp<sup>5</sup>), who find that the "synergistic" effect may be obtained with a large variety of pure fatty acids, as well as with Prof. Laqueur's and other extracts. These authors also showed that the activity of testosterone varies according to the kind of oil in which it is dissolved. In paraffin oil, for example, it is inactive.

The work described below was begun as a study of variable factors in the assay of male hormones on the accessory reproductive glands (prostate and seminal vesicles) of castrated rats, but subsequently became relevant to the problem of "activation" of male hormones.

#### TECHNIQUE

The methods used were those described by Deanesly and Parkes.<sup>6</sup> Rats were castrated at 40–60 g. body-weight and used not less than one month later. Within these limits the results, though individually

variable, were found to be independent of the exact age, size, and time after castration of the rats. As a precaution, however, all sets of comparisons except one were carried out on batches of 20-30 rats castrated, and later injected, at the same times.

The hormone was administered subcutaneously in ten equal daily injections to groups of 5 or 10 similar rats which were killed one day after the last injection. For comparison of the effectiveness of various methods of administration the standard total dose per rat was 10 mg. androsterone or 2 mg. testosterone.

AMOUNT AND NATURE OF OIL

As already mentioned <sup>6</sup> (and see also <sup>7</sup>) we have obtained striking results by varying the amount of oil in which the hormone is administered. Three

Effect of volume of arachis oil solution on the response of the prostate and seminal vesicles to 10 mg. androsterone and 2 mg. testosterone. --- = Androsterone. — = Testosterone.

groups of 5 rats each were given the standard 10 mg. of androsterone in a total of 1, 2, and 5 c.c.m. arachis oil respectively per animal. The experiment was subsequently repeated on a different batch of rats, with corresponding effects. The combined results, given in Table I. and the Figure, indicate that

TABLE I

Effectiveness of 10 mg. androsterone in different amounts of arachis oil

Total amount of oil (c.c.m.).	Average weight of—

10 rats in second group, 5 in others.

increasing the volume of oil by five times more than doubles the effectiveness of 10 mg. of androsterone.

A similar experiment with 2 mg. testosterone (in which, however, the groups of rats were not of the same batch) gave a similar result (Table II.).

Our first inclination was to ascribe this effect to alteration of the conditions of absorption, possibly to spreading the absorption more evenly over the interval between injections, but in view of the results

with x-substance, the increased response might have been due to the presence in the arachis oil of free fatty acid or some other accessory substance. Various experiments were therefore carried out to throw light on this problem :—

(a) The standard dose of androsterone was administered in a total of 5 c.c.m. arachis oil, but each daily dose was given as five separate injections of 0.1 c.c.m. in different parts of the body.

(b) The standard dose of androsterone was administered in a total of 1 c.c.m. arachis oil, the daily injections all being on the left side of the rat, while 4 c.c.m. of blank arachis oil was given over the same period on the other side.

The first of these experiments gave a result similar to that obtained by the administration of the standard dose in a total of 1 c.c.m. oil. The second gave only a slightly higher result which, allowing for the partial mixing which may have taken place under the skin, points to the same conclusion—i.e., that the increased efficiency of the larger volumes of oil solution is not due to the presence of accessory substances in the oil, but is due to some local action at the site of absorption. This conclusion was supported by an experiment in which we used a pure solvent, 1:2 propylene glycol, which is miscible with both oil and water. The standard amount of androsterone given in a total of 2 c.c.m. of this medium produced the highest response to that dose so far obtained, the results with an increased volume of the same solvent being rather lower. Whatever the explanation of the high efficiency of this solvent may be, it is clear that the conditions of absorption from it are very different from the conditions of absorption from oil, and that it does not contain accessory substances. Tests on the use of various oils as solvents showed that castor oil was about as effective as arachis oil, but that olive oil was much less so (Table III.). It

TABLE III

Effectiveness of 10 mg. androsterone in 2 c.c.m. of various media

5 rats in each group.

is clear from these experiments that in comparative work with male hormone compounds the technique must be carefully standardised; the above experiments may well explain some of the discrepancies in the results of different workers.

ADDITION OF PALMITIC ACID

At this stage we were fortunate in being able to discuss our findings both with Dr. Miescher and Dr. Freud. The former kindly gave us early information of the results he and his collaborators had obtained with various fatty acids.

The experiments shown in Table IV.\* were then undertaken and the following conclusions reached.

\* We understand that both Dr. Freud and Dr. Tschopp have performed somewhat similar experiments, but we have not heard actual details. (Added April 6th): Dr. Tschopp's experiments (Miescher, Wettstein, and Tschopp: Schweiz. med. Woch., 1936, lxi., 310) have apparently given similar results.

(a) The addition of palmitic acid to the oil solution of testosterone causes a great increase in response, much above that obtained by increasing the total volume of oil to 10 c.cm. (Table II.).

(b) The administration of palmitic acid in separate injections on the side of the animal opposite to that receiving the testosterone causes no significant increase in response.

(c) The definite increase brought about by the palmitic acid cannot apparently be attributed to synergism at the site of action of the hormone.

TABLE IV

Effectiveness of 2 mg. testosterone with 0.5 g. palmitic acid

Method of administering testosterone.	Average weight of—	
	Prostate (mg.).	Seminal vesicles (mg.).
In total of 5 c.cm. arachis oil solution	183	118
In total of 5 c.cm. arachis oil solution containing 0.5 g. palmitic acid ..	252	210
In total of 5 c.cm. arachis oil given on left side of the rat with 0.5 g. palmitic acid in 5 c.cm. oil given on right side .. .. .	171	135

10 rats in each group.

It may be added that experiments show that the increase in the effectiveness of testosterone caused by the addition of  $\alpha$ -substance or fatty acid is not obtained in capon tests,<sup>1</sup> and the addition of the substances therefore greatly increases the activity of testosterone on rats per capon unit. As we have already pointed out,<sup>6</sup> some such alteration of the ratio is necessary for testosterone to have the typical biological activity of testis extracts.

## DISCUSSION

The immediate problem is (a) whether the mode of action of fatty acids given in conjunction with testosterone is similar to that of the  $\alpha$ -substance described by the Amsterdam workers; (b) whether the fact that increased activity is produced by increasing the volume of oil has any bearing on the subject; and finally (c) whether there is any conclusive evidence of real synergism between the "accessory substances" and the hormone, at the site of action of the latter.

Freud<sup>8</sup> states that the purest preparations of  $\alpha$ -substance are very much more active than the fatty acids tested by Miescher, but this does not necessarily indicate any qualitative distinction. According to Freud, Dingemans, and Polak,<sup>3</sup>  $\alpha$ -substance activates androstanediol and testosterone, but not androsterone. The positive results with androsterone recorded in Table I. are thus presumably of a different kind from those obtained with  $\alpha$ -substance. Miescher and his co-workers have not apparently tested the fatty acids in conjunction with other male hormones than testosterone, but a single experiment in this laboratory suggests that the effect of 10 mg. androsterone in 5 c.cm. arachis oil (Table I.) is increased by the addition of 500 mg. palmitic acid.

The crux of the problem seems to be whether or not the "activating" effect is obtained by separate injection of the  $\alpha$ -substance, of the fatty acid, or of excess oil. For the last two, our evidence strongly suggests that the activating effect is only obtained when they are injected in intimate mixture with the hormone. It is therefore most difficult to see how the "activation" can be due to synergism at the site of action, and by contrast local effects at the site of injection are implied. A comparison may be made

with the increased efficiency of oestrone obtained by esterification or by subdividing the total dose into a series of frequent injections. The present results may similarly be due to slowing the rate of absorption and thus levelling the supply of active substance available to the animal, with a consequent decrease of wastage by excretion. Actually, in our experience, considerable heating is required to dissolve the palmitic acid and hormone in a suitable quantity of oil, and under such conditions the possibility of esterification of the hormone cannot be entirely excluded.

This doubt concerning the mechanism of the process, however, in no way alters the fact that, owing to the researches of Freud and of Miescher and of their co-workers, a method has been found of very greatly increasing the effectiveness of some at least of the extremely expensive male hormone compounds. A wide field of work has also been opened up in the possible application of this technique to other hormones.

## SUMMARY

An increase in the amount of oil solution, or the addition of palmitic acid to it, greatly increases the effectiveness of androsterone or testosterone. The effect is not obtained if the excess oil or the fatty acid is given by separate injections in another part of the animal.

We are greatly indebted to Prof. L. Ruzicka and Messrs. Ciba Ltd. for the supplies of androsterone and testosterone, while we wish to thank Dr. K. Miescher, Dr. J. Freud, and Dr. R. K. Callow for valuable information and discussion.

## Clinical and Laboratory Notes

## XANTHOMATOSIS OF THE SPLEEN

BY W. G. BARNARD, M.R.C.P. Lond.

CONSULTING HISTOLOGIST TO THE LONDON COUNTY COUNCIL; AND

G. E. BREEN, M.D. N.U.I., D.O.M.S.

SENIOR ASSISTANT MEDICAL OFFICER OF THE SOUTH EASTERN HOSPITAL

IN addition to the well-defined general xanthomatoses of Gaucher's and Niemann-Pick's disease and the more localised Hard-Schuller-Christian's disease, there are cases which do not belong to either of these groups. That described here is one in which the sole organ affected was the spleen, which was only moderately enlarged. The macroscopic appearance of its cut surface gave no indication of the widespread change in its pulp, which was almost entirely occupied by large cells closely resembling those found in Gaucher's disease, except that in the periphery of the cells were closely packed granules, stained by Sudan III. and osmic acid.

A breast-fed infant, aged 4 months, was admitted to the Brook Hospital on July 25th, 1934, certified as diphtheria, a routine swab having proved positive. She

was a small but well-nourished and well-proportioned baby. On examination, apart from a few dry râles over both lungs, she appeared to be normal. It is especially to be noted that there was no demonstrable enlargement of the spleen, liver, or superficial lymph nodes.

On the evening of the day of admission she was found to have a temperature of 103° F. A re-examination revealed nothing more than the mild bronchitis already referred to, which could hardly be regarded as an adequate cause of the pyrexia. The following day a mild gastro-enteritis

Section of spleen. ( $\times 360$ .)

set in, probably as the result of the change from breast to artificial feeding. This cleared up in a few days but the fever continued. Attention was therefore focused on discovery of a possible cause, but all investigations proved negative, including a Widal test and cultures from the blood and urine. Finally dentition, then in progress, was blamed, since the child but for the temperature could have been passed as normal. She took all feeds readily, gained a little weight, was lively and contented, and well above the average intelligence for her age. A close inquiry into the family history, with special reference to tuberculosis, was also without result. One fact, disregarded at the time, becomes interesting in retrospect: the father and one brother suffered from diabetes insipidus. Otherwise the family health was excellent.

The child was said to be continually "restless," especially at night. This became worse and culminated on August 19th in a convulsion. Two more convulsions occurred on the following day. As they were very brief it was not possible to reach the ward in time to see one, but from the descriptions supplied a diagnosis of tetany was hazarded, although there were no cardinal signs of this condition. Massive doses of a calcium-vitamin-D preparation—were therefore injected, and as the fits promptly ceased it was felt that the diagnosis had been correct and less potent tablets of the same preparation were subsequently included in the feeds.

For a week no further convulsions occurred. The fever persisted with morning remissions, but the baby appeared so well that the mother pressed to be allowed to take her home. On August 27th however another fit occurred, and another on the following day. The injections were again resorted to, but this time without result, and fits recurred at intervals of from 12 to 48 hours. Despite this the general condition remained remarkably good, and there was one week of apyrexia, but this did not have any influence on the number or severity of the attacks. Further investigations were made. Lumbar puncture yielded a normal cerebro-spinal fluid, and the Wassermann reaction was negative both in the fluid and in the blood. The urine remained clear. The fundi were normal, as were the superficial and deep reflexes. The feeds were suspected and altered; fat was withheld for a week and the sugar content was varied. All changes were equally well tolerated, all the feeds being taken

and the stools were normal, but the weight gradually went down. No medication seemed to influence the frequency or severity of the fits or to diminish the restlessness. This, which seemed at first no more than a mild athetosis, became more and more violent, so that the description "continuous convulsion" could much more accurately be applied to it. The child lay on her back thrashing with the arms and legs, the eyelids blinking, and the facial muscles twitching continuously. At intervals of about half an hour the limbs would flex slowly and deliberately, the lids retract and the pupils dilate, and the colour change to an extreme pallor. It seemed that death must ensue immediately, but in a minute or less the colour would revive and the movements recommence. In these seizures there was no incontinence, the heart action was unchanged, the pupils would still react to light, and the reflexes were normal. As it was imperative that some rest be procured at any cost the more powerful hypnotics were given. These did something to diminish the violence of the movements but nothing to alter the frequency. On Sept. 8th stupor supervened and death occurred the same day.

*Post-mortem report.*—A moderately well-nourished, well-developed, pallid female infant; slight jaundice of conjunctivæ. Heart normal; foramen ovale patent but valvular; remainder of fetal circulation closed. Lungs oedematous; slight purulent bronchitis and small patches of broncho-pneumonia. Liver: slight fatty degeneration.

The spleen (7 by 3 by 1 cm.) was enlarged and purple, having a smooth red to reddish-grey cut surface with distinct Malpighian bodies (0.1 cm. diam.). Kidneys: cloudy swelling. Adrenals: pale yellow cortex and grey medulla. Brain: vessels congested, particularly in the basal ganglia; thrombosis of right choroid plexus; middle ears clean. Ribs: normal line of provisional calcification at costochondral junction.

*Histology.*—Tissues examined were the spleen, liver, lung, kidney, pancreas, thyroid, pituitary, basal ganglia of brain, mid-brain, cerebellum, medulla, and choroid plexus. These were all stained with hæmatoxylin and eosin and with Weigert's iron hæmatoxylin and van Gieson's stain; in addition frozen sections were made of the spleen and liver and examined unstained, after heating, and stained with Sudan III. There was fatty change in the liver, oedema, and broncho-pneumonia of the lung, cloudy swelling of the kidney, and thrombosis of the choroid plexus. Apart from these and the changes in the spleen, the remaining organs were normal.

In the spleen the Malpighian bodies, trabeculæ, and blood-vessels were normal. The remainder of the spleen was largely composed of trabeculæ and small clusters of large cells having a vacuolated foamy protoplasm. The outline of each group of cells was distinct but the individual cell outlines were occasionally lost. The nuclei varied from round and oval to narrow crescent-shaped nuclei forming part of the border of a "blown out" cell. A delicate chromatin net and a small nucleolus could be made out in those which were least squashed. In frozen sections granules, staining a golden brown colour with Sudan III. and black with osmic acid, were present in the periphery of all the foam cells, but they did not fill the whole space and with a polarising microscope doubly refractive bodies were also present.

#### DISCUSSION

The cells in the spleen were similar in size and arrangement to those found in Gaucher's disease, and they also contained a substance which would not stain with the ordinary fat stains. In addition, however, they contained, particularly in the periphery of the cells, granules which stained readily, and also granules which were doubly refractive with polarised light. The limitation of the change to the spleen and the presence of these stainable "fats" appeared to rule out the possibility of this being genuine Gaucher's disease. The localisation of the abnormal fat-containing cells to the spleen, and their size, make it impossible to label the case one of Niemann-Pick's disease, for the characteristic of

that disease is the widespread distribution of the foam cells, which infiltrate the entire splenic pulp, diffusely infiltrate the lymphatic glands of the cœliac and hepatic groups, infiltrate the bone-marrow, intestinal mucosa, lung, and perivascular tissues of the brain. The cells stain irregularly with the usual fat stains and contain doubly refractile bodies.

Whether the family history of diabetes insipidus could in any way be associated with the condition it is now impossible to say. There were no histological abnormalities either in the pituitary or in the pancreas.

We are indebted to Dr. J. V. Armstrong of the Brook Hospital for permission to publish details of this case.

## HENOCH'S PURPURA CAUSING ACUTE OBSTRUCTION TWICE IN EIGHT DAYS

By TINA GRAY, M.B. Glasg.

DISPENSARY SURGEON TO THE GLASGOW ROYAL INFIRMARY

THE following case seems rare enough to warrant publication. I have not been able to find a similar one recorded in the literature.

The patient, a miner aged 21, was admitted to the medical side of the Glasgow Royal Infirmary on Jan. 12th, 1936, with Henoch's purpura. Eighteen months previously he had developed joint pains with purpuric spots. Attacks had recurred every two or three weeks till the beginning of 1936, when there was a much more severe attack and acute pain was felt in both ankles and the joints were swollen; two days later the left knee was similarly affected. These joint pains were accompanied by pain in the right hypochondrium, with nausea and vomiting; the vomitus was black, and the pain lasted for three days. On Jan. 11th the left wrist and both elbows became swollen and painful, the abdominal pain and vomiting returned, and he was admitted to the infirmary.

On admission there was a rash, papular and bright red on the extensor surfaces of the forearm, hand, and leg, especially round each elbow. The tip of the spleen was palpable. The patient appeared drowsy and exhausted.

The investigations were as follows:—

Blood examination: Red cells, 3,700,000; white cells, 5200; hæmoglobin, 88 per cent.; colour-index, 1.0. Bleeding-time diminished (2 min.); coagulation-time slightly increased (5½ min.); film showed well-stained red cells of uniform size and shape; leucocytes normal; numerous platelets were seen. Wassermann reaction negative. Ophthalmic examination: no abnormality. Vomitus, Jan. 12th–26th, negative for blood; fæces, Jan. 20th–26th, positive; urine, Jan. 14th–26th, positive.

The following treatment was given: Hæmoplastin 6 c.cm., once after admission; autohæmotherapy 10 c.cm. 5 times; sod. salicyl. and sod. bicar. grs. 15 t.i.d.

On Jan. 26th he developed very severe colicky abdominal pain and vomiting. A tender mass was palpated in the abdomen and he was transferred to the surgical side. The patient looked very ill, was restless, and in great pain; obstructive vomiting was present and he was passing blood and mucus per rectum. He was taken into theatre immediately. Mr. G. T. Mowat opened the abdomen with a paramedian incision. An intussusception caused by hæmorrhage into the wall of the gut was found reaching to the middle of the transverse colon, commencing at the iliocecal valve. This was reduced and the appendix, which was very congested, was removed. Much fluid was present in the pelvis and a stab puncture was made to allow for suprapubic drainage.

The patient made satisfactory progress till a week later, Feb. 1st, when he again complained of severe colicky abdominal pain similar to that before his operation. He looked desperately ill and blanched. The abdomen was rigid and very tender in the cœcal region, and obstructive vomiting recommenced. He had the temperature of collapse and a pulse-rate of 108. I reopened the old wound. Quantities of blood welled up and bubbles of gas, then distended fluid-filled small intestine escaped.

Beyond the cœcum the large bowel was collapsed. There was a gangrenous patch about the size of a crown piece on the cœcum at the site of the previous intussusception. At a distance of 8 in. and 12 in. from the cœcum the ileum was firmly fixed down and kinked by organised blood clot; at these places the peritoneal coat and the mesentery were split and the walls of the bowel thickened and purple with the extravasated blood, these conditions forming a complete obstruction. His condition made resection out of the question, and as the bowel, though blocked, was possibly viable a lateral anastomosis between the ileum and the transverse colon seemed the only thing to do to tide him over the crisis. This I did and invaginated and overstitched the gangrenous patch on the cœcum. The clots were cleared from the mesentery and the peritoneum stitched. Hot saline solution was introduced and the wound resutured. A drainage-tube was replaced in the pelvis through the old stab puncture.

The sickness stopped after the operation and the bowels moved naturally a day or two later. He was put on daily doses of Calcium Sandoz 5 c.cm., and Campolon 2 c.cm. intramuscularly. On Feb. 4th and again on the 20th 700 c.cm. of citrated blood was transfused. Even after the first transfusion the patient's condition improved tremendously. His appetite improved, there was no melæna, and the hæmaturia ceased. He looked and felt well. The red cell count was now 5,390,000 per c.mm.; there were no abnormal cells in the film and numerous blood-platelets were present. The superficial layers of the wound broke down and required resuture, but this did not delay his convalescence unduly. He was up on March 9th and went home on the 13th.

I am indebted to Mr. G. C. Swanson, in whose wards the patient was treated, for permission to publish this case.

## NEW INVENTIONS

### HYSTERECTOMY FORCEPS

THESE forceps are made both straight and curved. They are 8½ in. long and have longitudinal grooves instead of transverse serrations, distinctive shaped bows, and Kocher tooth at tip. The grooves add greatly to the ease of panhysterectomy operations, vaginal or abdominal, in that the slipping of tissues

out of the forceps whilst tying ligatures is obviated. Panhysterectomy is the hysterectomy of election owing to the danger of cancer of, and chronic discharge from, the cervical stump. In no operation is annoying hæmorrhage after a slipped ligature so common or so difficult to recontrol, especially in large stout women. The instruments are not too long, and the Kocher tooth holds up the tissues as they bunch together along the grooves as the ligature tightens and the forceps opens. They are manufactured by Messrs. Allen and Hanburys Ltd., Wigmore-street, W.

W. McK. H. McCULLAGH, F.R.C.S. Eng.

## MEDICAL SOCIETIES

OPHTHALMOLOGICAL SOCIETY OF  
THE UNITED KINGDOM

Mr. R. FOSTER MOORE presided at the annual congress of this society held from April 2nd to 4th at the house of the Royal Society of Medicine. A large number of individual papers were read and discussed. At the opening session a discussion on

**Ophthalmia Neonatorum**

was opened by Mr. J. D. MAGOR CARDELL, hon. secretary of the society. As early as 1545, he said, the English edition of the "Rosengarten" stipulated that after the child was born, the cord cut, and the baby swaddled, the eyes should be carefully and frequently washed out with warm water. This advice was elaborated and repeated by various other writers, and since 1879 advance had been made by the education of doctors, midwives, and mothers, by compulsory notification, and the provision of antenatal clinics and institutional treatment.

The commonest of several sources of infection was the discharge from the maternal passages and adnexa, evidence of which could be found on the infant's face and especially on the eyelashes. The child could infect itself by unwashed hands which had not been secured to its body. If the mother had vulvitis, infection could be carried by her fingers to the child's eyes. In the examination the non-infected eye should receive first attention; when an eye-dropper was used the drop should not be "touched off" on the lid. Some of the modes of infection were only likely in poor surroundings, but they accounted for a certain number of infected eyes. The character of the discharge varied greatly. Cases were frequent in which for a time there was nothing but a stickiness of the lids, and—without possibility of further infection—the typical purulent discharge followed after an interval. The discharge might be thick, watery, or sanious. Mild infection might be either gonococcal or non-gonococcal; if gonococcal the discharge lasted (on the average) nine days longer. In marasmic, premature, or sickly children discharge might be slight or almost absent; in many cases its amount could be reduced without much influence on the ultimate course of the disease. Discharge imprisoned behind swollen lids had an adverse effect on the cornea, which might also suffer from excessive force in opening the lids or the unskilled use of silver nitrate. Œdema of the corneal epithelium produced a haze which cleared up rapidly; if marked and localised it carried a risk of ulceration. Deeper keratitis was more likely to be followed by ulcer. In all these conditions the utmost delicacy of handling was essential.

Early and efficient treatment could in most cases prevent ulceration, provided the child was not syphilitic. There were three types of ulcer. First the puncture or pin-hole ulcer, which might perforate in 48 hours. Frequently this was gonococcal, and little scarring resulted. A slight trauma was often the cause. The second kind was the large ulcer with a good deal of surrounding keratitis, and this mostly perforated. The third was a sloughing of the cornea, occurring in premature and weakly babies. In the presence of severe dacryocystitis the eye condition became more chronic, but the lacrimal gland itself was rarely involved. Rhinitis in slight degree was not uncommon. Gonococcal arthritis was fairly common in the mother but rare in the infant. The duration depended on the intensity

of the infection, the child's resistance, and the efficiency of treatment. Prognosis was better if institutional treatment could be obtained, and if the child was breast-fed. In premature infants home treatment frequently ended in disaster. In 73 per cent. of the cases he had seen the discharge ceased in both eyes on the same day, independently of the difference in the amount of discharge. At St. Margaret's Hospital the patient was sent home after all discharge had ceased and at least seven days had elapsed without a recurrence. There were only 3 per cent. of return cases, and even this rate was higher than it would be but for the over-anxiety of doctors and mothers in the presence of slight stickiness of the lids. Corneal involvement was easily missed unless examination was made under good conditions. The presence of a corneal ulcer was always a grave menace to vision; the end-result depended on its site and type and on the treatment. Sloughing of the cornea was often followed by extrusion of the lens, panophthalmitis, glaucoma, and loss of sight. Diagnosis was simplified in the multipara by a history of previous babies with ophthalmia. The ordinary ophthalmia must be differentiated from that caused by silver nitrate; here the microscope was useful.

Methods of treatment were very numerous, and to judge by the reports, said Mr. Cardell, all were equally successful. There was, he thought, a tendency to overtreat. He stressed the value of fresh air in assisting a cure. Irrigation was necessary, but with the minimum of force, and the stream should be directed from the inner to the outer canthus, so as to avoid carrying pus from one eye to its fellow. Irrigation was best carried out by two nurses: one to apply the treatment and manipulate the upper lid, the other to steady the child's body and head and take charge of the lower lid. A gentle drawing of the lids apart at the same time massaged the cornea and coaxed pus out of the fornices. At St. Margaret's, eusol one in ten had been successfully used for many years. In the initial stages silver salts rapidly killed the bacteria in the most superficial parts of the conjunctiva, but after they had penetrated well below the surface they were protected. Ice and cold lotions should not be persisted in if the lid swelling did not subside in a few hours. He had found no success from vaccine therapy. Atropine, preferably dissolved in castor oil, was the accepted treatment of keratitis and corneal ulcers. Treatment of corneal nebulae was important but sometimes neglected.

For a preventable disease the incidence was not falling at the rate it was reasonable to expect. In the period 1927-29 it fell only from 8.66 per 1000 births to 8.11 from 1930-32. Primarily, said Mr. Cardell, education was at fault. Of the cases admitted to St. Margaret's 60 per cent. had corneal involvement, 6 per cent. corneal abrasions or ulcers. A factor in the reduction of incidence might be its inclusion in the medical curriculum; but on the whole, midwives received more practical instruction about ophthalmia than did the medical man to whom cases were reported. Every case of ophthalmia neonatorum in practice should be regarded as an emergency.

## STANDPOINT OF PREVENTIVE MEDICINE

Dr. H. P. NEWSHOLME, medical officer of health for Birmingham, said the public health officer is dealing with gonococcal ophthalmia diluted by other, usually less grave, kinds of ophthalmia. He

learns of cases of ophthalmia mainly from two sources, the medical practitioner and the midwife. The practitioner is required to notify "purulent discharge from the eyes of an infant commencing within twenty-one days from the date of its birth." The midwife must report any "inflammation of, or discharge from, the eyes, however slight." In both cases the issue is the practical one of drawing attention to any potential danger; neither doctor nor midwife is asked to select the gonorrhœal cases for report. The number of notifications vary enormously from area to area. High figures may connote heavy incidence or an energetic health service. The prophylactic rinsing fluid, especially the stronger solution of silver nitrate, may itself be the cause of a catarrhal ophthalmia of chemical origin. The incidence will appear higher in areas where cases of ophthalmia are brought readily to an eye hospital. Birmingham had almost the highest rate in the country, with a definite increase during recent years, but impaired vision or blindness had diminished. Starting from May, 1911, when ophthalmia became compulsorily notifiable, and taking 5-year periods up to and including 1935, the number of cases of partial or complete impairment of vision from this cause in infants was in successive 5-year periods 37, 47, 21, 35, and 8, the numbers for the last five years separately being 3, 4, 1, 0, and 0. Pressure had been put on practitioners and midwives to send all cases to the Birmingham and Midland Eye Hospital, which was subsidised by the local authority. The routine use by the midwives of one per cent. silver nitrate led to a considerable proportion of the cases attending the hospital on account of irritant and not infective ophthalmias. Formerly half per cent. solution was in use; this was increased to one per cent. in a largely successful attempt to reduce the number of damaged eyes, but with a concomitant rise in total notifications. The substitution of acriflavine for silver nitrate was now to be tried. But the increase in notifications in Birmingham masked an improvement quite as significant as that indicated by the dwindling prevalence of blindness. From 1928 each case of purulent ophthalmia attending the hospital had been examined (film and culture) by Dr. E. W. Assinder with the following results:

Year.	Cases.	Gonococcal and percentage.	P.G.T.
1928 ..	481	29 (6.0)	6.0
1929 ..	478	19 (3.9)	3.9
1930 ..	571	20 (3.5)	4.1
1931 ..	622	14 (2.2)	2.9
1932 ..	624	12 (1.9)	2.5
1933 ..	537	9 (1.7)	1.9
1934 ..	554	10 (1.8)	2.1
1935 ..	644	5 (0.8)	1.0

P.G.T. = Percentage gonococcal assuming the annual total of cases to have been identical with that for 1928 (481) in each subsequent year.

The falling gonococcal infection rate was far from being accounted for by mere dilution with non-gonorrhœal cases. This decrease might conceivably be the result of three factors: (1) decrease in female gonorrhœa, (2) more effective treatment, and (3) improved midwifery service. From an analysis of data drawn from the Birmingham venereal diseases clinics he did not feel justified in drawing any conclusion as to a change in prevalence of gonorrhœa; at any rate the number of attendances of infected women for specific treatment had increased greatly. Better care before, during, and after labour was undoubtedly a dominant factor in the reduction of gonorrhœal ophthalmia. In Birmingham 10.5 per

cent. of the total persons certified under the Blind Persons Act were blind through ophthalmia neonatorum; but since certification under the Act began at the age of 16 years, it did not reflect the improvement of recent years.

Dr. Newsholme then reviewed the measures taken in Birmingham for the prevention of ophthalmia neonatorum, including the 40 weekly municipal antenatal clinics at which 50-60 per cent. of all women delivered during the year attended on an average 3 to 4 times, the provision of three maternity beds in the venereal diseases clinic, the routine use by midwives of silver nitrate drops, and the facilities provided at the eye hospital. Notification was all-important, and omission or delay to notify had been the main factor in the few recent cases of blindness. The specialist service arranged by the eye hospital, in conjunction with the health committee of the city council, provided (1) out-patient examination and treatment at any hour of day or night, (2) beds to which the more acute cases could at once be admitted at public charge, and (3) provision of two extern nurses to visit the homes between the hospital attendances.

Granted the provision of facilities on these lines, said Dr. Newsholme, it appeared to him an act of almost criminal folly for a general practitioner to retain a case of even moderately acute ophthalmia under his own care, unless he had unusual experience in their treatment and exceptional nursing service available.

#### BACTERIOLOGY

Dr. S. H. BROWNING said he doubted whether bacteriological cleanliness was a practical proposition. The treatment of ophthalmia depended to some extent on the particular organisms found in the discharge, as also must the prognosis. The most skilled must often have difficulty in distinguishing clinically ordinary gonococcal from pneumococcal and staphylococcal infections of the eye. Treatment by vaccines and serums had not been successful. He agreed that many cases of ophthalmia neonatorum were overtreated. Some cases showed the presence of several virile bacteria. He had not found the complement-fixation test of any great value in gonorrhœa. Syphilitic babies with ophthalmia neonatorum almost always did badly. Of a number of infants infected with syphilis, only 48 per cent. recovered without loss of sight, whereas of non-syphilitic cases 81 per cent. recovered without loss. Recently the pneumococcus had been found more frequently than formerly in all eye diseases. When several organisms were present it was often found that the mother had been wiping away the baby's eye discharge with an apron she was wearing and which did duty for a variety of purposes.

#### DISCUSSION

Prof. M. MARQUEZ (in a paper read in his absence) said that the basic treatment should be silver nitrate. In many cases excessive treatment brought about greater evils than those it was sought to cure. He strongly condemned the use of the silver-nitrate stick; a solution would bring about the best results without danger. Care must be taken that chemical irritation did not enhance the inflammation due to the bacteria. The wonderful defensive power possessed by the tears and the eyes generally must always be remembered in treatment. Potassium permanganate 1 in 4000 thrice daily was valuable. He was not convinced of the value of protargol. He did not find protein therapy necessary.

Sir JOHN PARSONS suggested caution in the interpretation of statistics about ophthalmia; some returns recently submitted to Prof. Major Greenwood had been found to be unsound. Credé's method was used in some public health departments; he thought it should be employed more generally.

Dr. A. J. BALLANTYNE said that in Glasgow there was no diminution in the number of cases of the disease reported over some years, but he did not doubt that the severity was much less than 20 years ago. Some of the cases he saw were due to silver nitrate irritation. In recent years he had seen little corneal involvement.

Dr. SPENCE MEIGHAN emphasised the need for repeated bacteriological examination in suspicious cases when gonococci were not at first found.

Mr. F. JULER commented on the fact that in ordinary hospital work in London the incidence of ophthalmia neonatorum was very low. When he was a student cases were always to be seen; now it was difficult to find one to show to students. There seemed a tendency now to use silver nitrate of less strength than formerly. In one large maternity hospital, among 44,357 live babies delivered, 180 (or 0.4 per cent.) had ophthalmia, while among 44,717 cases on the district it was 0.157 per cent., and this despite the fact that the institution was largely resorted to by the poor, and there were many unmarried mothers.

Mr. RANSOM PICKARD (Exeter) said that in Exeter and neighbourhood there had been a decided decrease in ophthalmia, but he saw a fair amount of chemical irritation of the eye following treatment. In no case however could he attribute a serious effect to the use of a chemical agent.

Mr. CHARLES GOULDEN ascribed the low incidence-rate in London hospitals generally to the work at St. Margaret's Hospital. Cases due to streptococci, he said, were the most shocking; the cornea seemed just to fade away. If the streptococcal form was at all frequent it would be some excuse for a low recovery-rate, as it seemed to defy all treatment. Ordinarily he trusted silver nitrate; all excess however should be neutralised, as the baby had no tears. In the adult ophthalmia should be treated without the cornea being touched with silver solution.

Mr. SOMERVILLE LARGE said that at the Rotunda Hospital, Dublin, 1 per cent. silver nitrate was the routine application, and if there was a second discharge a further drop was used an hour later. The number of chemical inflammations was small.

#### A Talking Book for the Blind

One evening session was chiefly taken up with a demonstration on a talking book for the blind. Sir ARNOLD LAWSON, who disclaimed any part in its production, said the idea which had been simmering in the minds of those who had the welfare of the blind at heart had come to fruition through the constructive ability of Sir Ian Fraser. For a large proportion of blind people Braille was a failure, only a limited number attained sufficient proficiency to be able to read by its means, and few of those over 40 had not had their touch coarsened by manual labour. This apparatus not only dispensed with Braille, but made the blind man independent of reading aloud by a friend. The difficulty to be solved had been the number of records needed on the basis of the ordinary 12 in. record working at 78 revolutions per minute, and playing four minutes—added to the need for frequent changing of records and the heavy postage. The new record revolved at 24 per

minute; its grooves were spaced at 200 instead of the usual 100 to the inch; it would last 25 minutes for each side, or nearly an hour per record. People with good broadcasting voices gave their services gratuitously, and some 30 books had now been put into circulation. Any blind person could join the library without charge; each volume was sent post-free, the receiver paying the return postage. Already 300 blind people were using the library.

Sir IAN FRASER remarked that the blind world was a small one, and until a device came into common use it was sure to be expensive to produce. That was the reason for working on the gramophone record, which was practically universal.

#### LIVERPOOL MEDICAL INSTITUTION

At a meeting of this institution on March 19th, with Mr. G. C. E. SIMPSON, the president, in the chair, a paper on

##### Gas-air Analgesia

was read by Dr. R. J. MINNITT. Since February, 1934, he said, when he read his first paper on the subject, many thousands of patients had the benefit of gas-air analgesia, and nearly 400 apparatuses were employed in various parts of the world. In analysing 1025 cases in which it was used in childbirth in the Liverpool hospitals during 1933-35, he compared the findings with those of the British College of Obstetricians and Gynaecologists, and found but little difference. Criticisms in the College's report, regarding the weight and bulk of the apparatus, were answered with a description of a midwives' model in attaché case, weighing 15 lb. without cylinder. The cost of the nitrous oxide used was not high if leakages were prevented, and in cases conducted by himself the amount of gas used was about 25 gallons per hour. As labour was accelerated by the use of gas and air, an obstetric cause should be sought in cases where it appeared to be retarded. Dr. Minnitt said that the apparatus had been used with great success in the wards of the David Lewis Northern Hospital, Liverpool, for the purposes of analgesia for painful dressings, and suggested that it should be provided in the out-patient department of every hospital. It had also been adapted for use in the preparation of painful dental cavities.

Miss RUTH NICHOLSON pointed out that in the recent investigation, by the British College of Obstetricians and Gynaecologists, of the various methods of inducing analgesia, Dr. Minnitt's was the only one found to be safe and efficient for the use of midwives.

Dr. JOHN GRAHAM said that he had used a Minnitt gas-and-air apparatus for about a year. Most patients were enthusiastic, pain was greatly relieved, and noise was very much less, relations consequently being much less troublesome. The machine was quite easily portable, supplies of gas were easily obtained, and the speaker's average cost was about 6s. per case, using about 15-25 gallons of gas per hour. A midwife with no previous experience had used the machine satisfactorily on several occasions after a few minutes' explanation. Dr. Graham thought that the cost would be very greatly increased by leakages of gas, but this was obviated by judicious use of the spanner provided. He hoped that the day might never come when he would have to conduct midwifery cases without gas-and-air analgesia.

Dr. A. WINFIELD said that, having used Dr. Minnitt's apparatus on some 50 or so cases, and

having found it efficient for producing analgesia in a good proportion, he always carried it. Low forceps delivery of multiparæ had been performed without pain, and primiparæ had been delivered without operative interference with great diminution, if not always absence, of pain. This had been effected by blocking some of the air inlets to increase the concentration of nitrous oxide during the last few pains,

but Dr. Winfield felt that, in his attempt to make an apparatus safe for use by people of no experience in the administration of anæsthetics, Dr. Minnitt had sacrificed a good deal of flexibility. An attempt to use the apparatus for small repairs of the perineum had not met with much success.

Mr. J. T. MORRISON read a paper on chronic empyema.

## REVIEWS AND NOTICES OF BOOKS

### Industrial Medicine

By W. IRVING CLARK, A.B., M.D., Assistant Professor of the Practice of Industrial Medicine, Harvard School of Public Health, Boston; and PHILIP DRINKER, S.B., Ch.E., Associated Professor of Industrial Hygiene at the School. New York: National Medical Book Company, Inc.; London: H. K. Lewis and Co., Ltd. 1935. Pp. 262. 13s. 6d.

INDUSTRIAL medicine is defined as "the practice of medical supervision, preventive medicine, and public health within the confines of an industry" in this book, which aims at assisting the United States doctor to understand the conditions under which his patients work, and at informing him of "standard practice in the industrial medical field." The problems confronting such a doctor may be divided into two groups: maintenance of the health of workers, and diagnosis and treatment of minor sickness and of injury. The authors point out that prevention of industrial disease is largely an engineering problem, its basis being the separation of the toxic or irritating substance from contact with the worker. In no other field of medicine is there such a close relation to the engineering profession, and where there has not been close coöperation between physician and engineer the main problem stated above has remained unsolved.

The first three chapters are devoted to the organisation of departments in industrial medicine and surgery, together with the general scope of industrial medical service and the keeping of sickness records. Four chapters are devoted to pneumoconiosis, much more attention being paid to particle size than to descriptions of the working conditions which constitute the hazards. This is in accord with the modern conception of the causation of the disease by the very fine particles, whereas many of the preventive measures formerly relied on are now known to affect only the larger particles. The discussion on the effects of dust challenges the evidence, now generally accepted as conclusive, that the solubility of quartz in the biochemical sense is the basis of the specific cellular necrosis which it causes. Experimental evidence as to the relative harmlessness of artificial abrasives such as silicon carbide and aluminium oxide is detailed.

In the chapter on lead poisoning insufficient emphasis is placed on the nature of the conditions which give rise to the disease. It cannot too often be brought home to the students of this subject that breaking a white lead stack containing 150 tons of white lead must be more harmful than handling lead cable or metallic lead, or even the repeated use of the plumber's blowpipe for wiping joints. The section on metal fume fever is an excellent summary of the work on this subject by one of the authors. The section on asphyxia and artificial respiration gives in detail the use of oxygen-carbon dioxide, and describes how teams of men are trained to apply the Schäfer method of artificial respiration. The last chapter deals with the prevention of industrial

disease, and gives in detail the means of protection against the effects of accidents. There are many illustrations, most of them of theoretical rather than practical interest. Amongst the striking points illustrated is a curve showing the beneficial effects of oxygen-carbon dioxide on patients seriously gassed with carbon monoxide. The book is well printed and the bibliography covers 20 pages. The precise style of writing is marred only in one place—namely, where directions are given for cutting two pieces of material the one the size of a dime and the other the size of a fifty cent piece. It is time that authors writing on scientific subjects should give such measurements in centimetres.

Readers will find in this book much precise information, especially on scientific investigations into industrial problems.

### Early Diagnosis of Malignant Disease

By MALCOLM DONALDSON, F.R.C.S., M.B., B.Ch., F.C.O.G., Physician Accoucheur and Director of Cancer Department, St. Bartholomew's Hospital, and Gynæcological Surgeon, Mount Vernon Hospital; STANFORD CADE, F.R.C.S., Surgeon to Out-patients, Westminster Hospital, and Surgeon, Mount Vernon Hospital; WILLIAM DOUGLAS HARMER, M.C., F.R.C.S., Consulting Surgeon, Throat Department, St. Bartholomew's Hospital, and Hon. Surgeon, Mount Vernon Hospital; R. OGIER WARD, M.Ch., F.R.C.S., Assistant Surgeon, St. Peter's Hospital, and Genito-urinary Surgeon, Mount Vernon Hospital; and ARTHUR TUDOR EDWARDS, M.D., M.Chir. Camb., F.R.C.S. Eng., Surgeon, Westminster Hospital, Brompton Hospital for Diseases of the Chest, Queen Mary's Hospital, Roehampton, and Mount Vernon Hospital. London: Humphrey Milford, Oxford University Press. 1936. Pp. 168. 8s. 6d.

If there is a phenomenon in the life-history of cancer as striking as its relentless course it is the clinical silence of its initiation. It might even be said with some truth that the early diagnosis of malignant disease does not exist except as an accidental occurrence. In the majority of cases even external cancers, cancers of the breast, for example, pass unnoticed by patients until they are well established. It follows that as a rule the general practitioner is given little opportunity for early diagnosis. It would seem then, if their title is taken literally, that the authors of this book have set themselves an impossible task; but it does not follow that their book will not be useful. The reader will find in it an account, a very good account, of the clinical features of what may, in this enlightened age, be called established cancer of the breast, the female genital organs, the mouth, the larynx, the thorax, the abdomen, the urinary organs, the skin, and the bones. The teaching is that which is now orthodox in the best medical schools. It is good to have the facts collected in a small volume, convenient for reference by the

practitioner who may have graduated long ago or may not have devoted sufficient attention to this most important branch of his education. It is a salutary reminder to him to keep on the alert; and since it is compiled by members of the staff of a hospital now entirely devoted to cancer, it evidently provides teaching which they have reason to think is not generally followed by those who have had the care of their patients previous to admission. Much as we may regret it, it is still apparently necessary to reiterate the essential points in the diagnosis of cancer, and no one could do so with more authority than the staff of the Mount Vernon Hospital.

### A Textbook of Midwifery

Eighth edition. By R. W. JOHNSTONE, C.B.E., M.D., F.R.C.S.E., M.R.C.P.E., F.C.O.G., F.R.S.E., Professor of Midwifery and Diseases of Women, University of Edinburgh; Physician, Royal Maternity Hospital; Gynaecologist, Royal Infirmary, Edinburgh. London: A. and C. Black Ltd. 1936. Pp. 471. 18s.

THE arrangement of the subject matter in this useful and popular book is successful in focusing the student's attention on broad principles before he is encouraged to master the details of obstetric practice. The physiology of pregnancy, labour, and the puerperium is described in the opening chapters, and the modern view of the nature and control of menstruation is also prominent. The pages—still too few—allocated to antenatal care and hygiene have been revised and slightly increased in number. Prof. Johnstone's teaching is so practical that the further extension of this aspect of the subject would be welcome. The chapters on the management of occipito-posterior positions and on the treatment of placenta prævia have been expanded. The many methods of dealing with a case of placenta prævia are described, and are critically compared in relation to their value, dangers, and difficulties. The excellent illustrations appear to be unchanged.

### Traité d'urologie

Third edition. By GEORGES MARION, Professeur de Clinique Urologique à la Faculté de Médecine de Paris; chirurgien de L'Hôpital Necker. Paris: Masson et Cie. 1935. Vols. I. and II. Pp. 1232. Fr.220.

SINCE 1928, when the second edition of this book was published, considerable advances have been made in urology. Not only have pathological conditions about which little was known been more fully investigated, but new methods of examination have been perfected. As an example of the former may be cited the work done on diseases of the bladder neck that formed one of the subjects at the International Congress of Urology held in London in 1933, and of the latter, the introduction of intravenous pyelography. Certain chapters dealing with these subjects are duly included in Dr. Marion's new edition. Another important change is found in that part of the work that deals with urethroscopy and cystoscopy. Instead of describing the appearances of the bladder and urethra under the various diseases that may affect these structures, they have been brought together in special chapters devoted to cystoscopy and urethroscopy. Another innovation is the inclusion of an entire chapter dealing with the technique of operations on the male genital organs. Whilst these are the main differences between the second and third editions, innumerable minor changes

will be found; a notable one is that the description of Marion's well-known operation on the female urethra for the treatment of such conditions as incontinence has been partially rewritten and is now so well illustrated that the reader is in a position to carry it out without any risk of departing from the exact technique recommended by the author.

It is perhaps a little disappointing that Dr. Marion has not dealt more fully with endoscopic resection of the prostate, a method of treatment which in selected cases has given excellent results. Most urologists would agree that the McCarthy operation and Harris's technique of prostatectomy with closure of the bladder are the two most important advances in prostatic surgery that the last ten years have witnessed. It is of course well known that in the treatment not only of minor forms of prostatic enlargement but also of sclerosis of the bladder neck, Marion favours an open operation rather than an endoscopic resection, and that a technique for resection of the neck by the suprapubic route has been described by him. Perurethral methods have, however, advanced so rapidly during the last few years that they now constitute an important method of treatment. It is only natural that in a work based on the experience of one man rather than on urological literature in general small space should be devoted to techniques which he does not himself favour, but it would have been wise to provide bibliographies at the end of each chapter containing references to alternative methods.

These new volumes are worthy of an author who must be regarded as among the most eminent and most experienced of European urologists.

### His Patients Died

By CLAUDE LILLINGSTON. Edinburgh and London: William Blackwood and Sons, Ltd. 1936. Pp. 317. 7s. 6d.

THIS novel, written by a doctor, is a tract upon euthanasia. The arguments are introduced in the form of cases so that the right of the medical profession to put a term in hopeless cases to an existence of perpetual and irremediable suffering may be estimated. The author is not a direct advocate of the practice; but his hero, who is not only an advocate but an actual performer, is drawn as a highly sympathetic character, and in this way the attitude that may in suitable cases be adopted is indirectly brought to the reader's attention.

Dr. Lillingston is happy in his hero when analysing the humane man's impulses; he is less happy in his descriptions of the environment or in the collection of material. Dr. Skooner's professional career is exciting, and the difficulties he meets with and the contacts he makes are certainly unusual. The method adopted by Samuel Warren—not by the way a doctor—of an imaginary case-book allowed the author to set down a string of terrible episodes where the want of relation between them actually added to their probability; Dr. Lillingston's endeavour to make a novel out of Dr. Skooner's experiences brings out the unlikelihood that any one man could have passed through such trials. Dr. Skooner is also endowed with a power of character reading for which it might be difficult to find scientific support, and scepticism as to his personality necessarily lends an air of unreality to his actions.

The book may be read and enjoyed as a thriller; but it is also an attempt to set out the contradictory aspects of a difficult question, and it deserves respectful attention for this reason.

# THE LANCET

LONDON: SATURDAY, APRIL 11, 1936

## ASHES AND WATER

THE clerk who, a century or so ago, gave up his job at the Patent Office because he felt there was nothing left to be invented, may or may not have been legendary, but his spiritual descendants are many and lack of imagination does not deter them from competing for the mantle of the prophet. It has been fashionable in the last year or two to aver that the days of mineral chemistry in medicine are numbered. No doubt the mere metals seem poor mutes in comparison with the infinitely versatile quartet carbon, hydrogen, oxygen, and nitrogen. But if man dances to the tune of a band of assorted sterols conducted by a dictatorial pituitary, he is none the less largely a matter of ashes and water.

Dr. McCANCE's Goulstonian lectures, which are concluded in this issue, show that apart from a few well-explored shafts, the army of research workers in the mineral field have done little more than scratch the surface. Although there is no reference to water in the title, it is natural that his observations concern water as much as mineral metabolism. The two are inseparable in biology, and there will be no end to problems involving them, as long as life itself eludes definition. Dr. McCANCE has broached so many interesting questions that there would be little point in attempting to sum up his lectures. It will be enough to comment on two points. In the first place his survey of the subject from the viewpoint of evolution is refreshing. Knowledge is accumulating so quickly at present that a research worker can be, and too often is, fully engaged in unearthing facts, without ever attempting to understand their significance. But "Why?" is more important than "What?" and if he is to avoid premature burial under a heap of sterile facts, he must pause from time to time and look where his burrowings are leading him. The need for frequent stocktaking has never been more imperative in the interests, not only of the research worker himself, but also of the general reader and the student. Tell a student that his kidneys concentrate urea something like a hundredfold during excretion, and he will accept the statement as one more relentless fact to be retained until he has passed his examiners and thereafter to be forgotten as soon as may be. Lead him up to the same fact with a picture of man's ancestors forsaking an environment of infinite wetness for a dry land in which water is a precious commodity, and he will have something to remember without effort and later, perhaps, to apply.

The second subject which invites particular comment is Dr. McCANCE's own work on experi-

mental salt-deficiency in man. Dehydration is encountered in many different clinical states, of which loss of intestinal contents by diarrhoea and vomiting and diabetic coma are familiar examples. However it is brought about, dehydration must be looked on as loss of body fluid as distinct from body water, for in order to survive the body cells require an environment not merely of fluid, but a fluid with a particular electrolyte pattern and an osmotic pressure somewhere near that of normal saline. As dehydration advances the body is accordingly forced to face an unpleasant dilemma—namely, the choice between desiccation and a radical change in osmotic pressure. Although the course of events in a particular case is determined by the nature of the loss, it may be said that as a general rule the body can safely yield a considerable fraction of its fluid reserves, and that alterations in electrolyte content appear only when the dehydration has attained serious proportions. When this stage is reached considerable care is necessary in restoring the lost fluid, and it is now generally recognised that to a very dehydrated person plain water may be extremely poisonous. In recent years, however, an important exception to this generalisation has been discovered in Addison's disease, in which lack of the cortical hormone leads to serious loss of sodium from the body, without proportionate loss of water, the salt content of the extracellular fluids becoming in consequence considerably diminished. The striking effect of salt solutions in relieving the symptoms of this disease suggest that sodium deficiency is largely responsible for these symptoms; but is this the whole story? Dr. McCANCE has attempted to answer this question by observing the effects of sodium depletion in the healthy human subject. Simple restriction of salt intake is not enough to cause significant loss of body sodium, for the kidneys respond by diminished excretion. The sweat glands, on the other hand, are less closely guarded, and Dr. McCANCE has been able, by combining a low salt intake with perspiration in a radiant heat bath, to reduce the salt reserves of the body by something like 30 per cent. Even so the rule mentioned above has held good, and a heroic amount of sweating has been necessary to get ahead of mere dehydration. However, the labour has not been in vain, and the symptoms and humoral changes observed by Dr. McCANCE and his volunteers are of much interest. The chief symptoms which they noticed were anorexia, nausea, lassitude, and muscular cramps. Their blood showed a deficit of sodium and chlorine, an excess of urea, and evidence of concentration in the shape of high values for protein, hæmoglobin, and cell volume. Apart from the cramps, which are reminiscent of the water intoxication which affects miners who drink too much water after sweating profusely, all these changes are characteristic of Addison's disease, and the parallel supports the belief that salt deficiency looms largely in the pathogenesis of that disorder. Two conspicuous features of Addison's disease are certainly missing—namely, pigmentation and low blood pressure—but perhaps

these are due to lack of the medullary hormone, adrenaline. The rise in blood-urea is especially interesting, for it occurs in many other forms of clinical salt deficiency, notably intestinal obstruction and diabetic coma; and, since nitrogen retention is linked up in the clinician's mind with renal damage, it has often led to serious errors in diagnosis. It is therefore important to know that simple sodium deficiency will increase the blood-urea in a subject with healthy kidneys. If Addison's disease is mercifully rare, intestinal obstruction and diabetic coma are common enough, and Dr. McCANCE'S lectures should stimulate others to pay more attention to fluid metabolism in everyday illnesses.

### AIR-CONDITIONING

HAVING conquered the air as a medium for locomotion, man has more recently turned his ingenuity towards the preparation of artificial atmospheres. The therapeutic properties of changes of air have been recognised since the dawn of medicine but until recent times such changes implied movement from one place to another. Air-conditioning now makes it possible for various types of climate to be provided successively in the same room, the only effort needed being that required for regulating the machine whose function it is to alter the temperature and humidity of the atmosphere. Up to the present the industrial uses of air-conditioning seem to have outdistanced the medicinal; the "Refrigerating Data Book," published by the American Society of Refrigerating Engineers, supplies information about the best atmospheres for carrying on a number of trades which include such diverse products as hygroscopic colloids, chewing gum, macaroni, mushrooms, and cigars. Among buildings with special requirements are mentioned picture theatres, churches, hotels in hot climates, and laundries. The needs of operating theatres, baby incubators, pneumonia and bronchitis inclosures have also been studied. A complete air-conditioning plant consists of (1) heat regulating mechanism (radiators and refrigerators), (2) humidity regulating mechanism (air washers, sprays, silica gel, calcium chloride, &c.), (3) cleaning mechanism (filters and dust collectors), (4) distributing system (fans, ventilators, &c.), (5) regulating system (thermostats, hygrometers, &c.).

In private dwellings heat regulation is a fairly simple matter, whatever the source of heat employed, and it is with humidity that the serious problems of air-conditioning are concerned. Americans are uncomfortable if the room temperature falls below 70° F. In the Eastern States the outside air in winter is frequently many degrees below zero and is consequently incapable of holding more than a very small amount of water vapour; if such air is heated to room temperature its relative humidity will be far too low for comfort and dryness of the throat will soon be experienced. It seems pretty certain in fact, as MOYER and FITZ have pointed out,<sup>1</sup> that were the humidity

increased a room temperature of 68° or less would be tolerated and found more healthy by those who now require 70°. The trade in antiques bears testimony to the high temperature and excessive dryness of American houses, in which the veneer of old furniture, which had remained in place for centuries in the cooler damper air of English houses, soon begins to peel off. The bowl of water on the radiator or in front of the gas fire is a rough-and-ready method of dealing with insufficient humidity. At the other end of the scale, probably the most unhealthy atmospheric conditions are those experienced in hot thundery weather when high temperature is combined with high humidity. With an outdoor temperature of 90°-100° F. it is not advisable to reduce the indoor temperature more than 15°-20° by means of refrigeration, but a more comfortable atmosphere can be provided by drying the indoor air—dehumidification, as American engineers call it—when heat loss is facilitated by evaporation. The filtration of air through viscous or dry cellular filters has the advantage of removing the antigens of asthma and hay-fever and of greatly reducing the number of micro-organisms it contains. One problem however awaits solution. Although electric fans are used to distribute conditioned air no one has yet succeeded in giving that freshness to indoor air that open windows provide. There is a sensation of staleness as though the air has been bottled and relief is experienced on emerging into the open air. Some engineers therefore recommend a combination of conditioning with direct window ventilation. When untreated air is admitted in this way a rough estimate of its volume, temperature, and humidity must be made and allowed for in calculating the composition of the conditioned air to be mixed with it.

Some further data are available. ELLSWORTH HUNTINGTON, in his book "Civilization and Climate,"<sup>2</sup> states that the room temperature conducive to the best mental activity is about 63° F., with the humidity held as high as possible. But unless double windows are put in to prevent condensation of moisture, it would be impossible in Dr. HUNTINGTON'S opinion to raise the humidity in the living-rooms of an ordinary house sufficiently to make so low a temperature tolerable. Writing of air-conditioning in the treatment of pulmonary tuberculosis, Prof. J. A. MYERS, of Minnesota, remarks<sup>3</sup> that it is no longer necessary to construct sleeping porches, erect tents on lawns, or to have the head protruding from the window during the sleeping hours. The air of the patient's room is conditioned at 68°-70° F. during the day and at 55°-60° for sleeping hours with a relative humidity of 40-50 per cent. These are indications of the direction air-conditioning is taking in America. The next few years will no doubt see a great extension of the principle in this country. If properly used it should be a factor in improving the public health, as the provision of pure air in adequate quantities and at the right temperature and humidity has obvious merit in heat waves,

<sup>1</sup> Air Conditioning. New York and London. 1933.

<sup>2</sup> Oxford University Press. 1924.

<sup>3</sup> Diseases of the Chest. New York. 1935.

foggy weather, and whenever large numbers of human beings congregate in a small space. At the same time a lead is required from the medical profession to determine what are the best atmospheric conditions for health. That free access of outdoor air, low temperature and low relative humidity, by raising the general health, help the consumptive patient to fight his disease can hardly be in dispute, and convincing clinical evidence will be required before the American standard of an indoor temperature of 70° F. with a humidity of 50 per cent. can be accepted as the optimum.

### SPIROCHÆTAL JAUNDICE IN ENGLAND

It is a striking fact that for twelve years after 1922—when C. M. WENYON and H. C. BROWN isolated the organism for the first time in this country from the case described by MANSON-BARR—only two papers were published relating to spirochætal jaundice in England. The first was an account of 4 cases in Norfolk by BURTON-FANNING and CLEVELAND in 1926; the second was LAWRENCE and OKELL's record of a case in which the patient was thought to be infected through post-mortem examination of dogs (1929). The year 1934, when HAMILTON FAIRLEY drew attention to the prevalence of spirochætal infection in London sewer-workers, was a turning-point in the history of the disease in this country. A paper by BROWN (1935) on its serological diagnosis led to his receiving specimens of sera from all over England, and we understand that in the past seven months no less than 37 of these have proved positive. These do not include the 3 cases in sewer-workers noted by ALSTON in 1935, nor the 9 sewer-men showing agglutinins in the blood described by ALSTON and BROWN (1935); but they do include the 12 cases of Weil's disease among coal-miners in Northumberland and Durham reported in our columns last September by SWAN and McKEON. Taking these figures as a whole we see that although only 5 cases were reported between 1922 and 1934, more than 40 have been brought to light in the last seven months. It is noteworthy that in all of them jaundice was a prominent sign. We have no data in this country from which we can compute the proportion of jaundiced to the total number of cases of Weil's disease, but if we consider the fact that in an epidemic in Holland SCHÜFFNER found that some 60 per cent. of all cases showed no jaundice, it becomes evident that the prevalence of the disease in England is probably much greater than has been supposed. This is supported by the fact that ALSTON and BROWN (1935) were able to demonstrate agglutinins in the blood of 9 out of 45 London sewer-workers who said they had never had jaundice.

There is no longer any question that Weil's disease ranks among the occupational diseases, but it is only in the last year that compensation has been officially recognised. In May, 1935, Judge DUMAS at the Westminster county court awarded £600 compensation to the widow and three children of a sewer-worker who had died

from infection contracted during the course of his employment, and last month Judge THESIGER at Newcastle county court awarded compensation to a miner who, among many others, contracted it from working in a rat-infected mine. The occupational incidence is of great assistance in the diagnosis; when a sewer-worker or miner complains of influenza-like symptoms associated with intense muscular pains Weil's disease should be suspected, and with the help of a well-equipped laboratory there is every chance of an early diagnosis which will allow of serum therapy being employed without delay. There is still some confusion, however, in the minds of many medical men regarding Weil's disease on the one hand and infectious jaundice on the other. Although infectious jaundice does occur in apparently sporadic cases, it generally takes the form of a more or less widespread epidemic chiefly affecting children. All degrees of severity are encountered, and in severe cases abdominal pain, hæmaturia, prostration, and ocular congestion associated with intense jaundice, make the condition hard to distinguish from Weil's disease, though it seldom produces the same intense muscular pain. It is here especially that the laboratory can be of value, for in the absence of any condition such as tonsillitis or any septic focus which confuses the blood picture, a differential count in spirochætal jaundice will show an excess of polymorphonuclear cells, whereas in infectious jaundice there will be an increase of mononuclears. The two diseases are wholly distinct in origin; the causal organism of infectious jaundice has not been discovered, but it is certainly not the *Leptospira icterohaemorrhagica*.

### THE BELFAST CONGRESS

THE congress of obstetrics and gynaecology held in Belfast last week was clearly an outstanding success. The first day's proceedings are summarised on another page and some account of the rest will be given next week. At the close of the meeting Mr. Eardley Holland voiced the general impression that the contributions were not only of unusual interest but were exceptionally well presented. Even the most serious deliberations seem to have been lightened by an element of mirth proper to a congress held on Irish soil. The members were delighted, for example, by the vein of irony with which Dr. Heyman thanked his "collaborators" for their assistance in allocating a series of 20 specimen cases of cervical carcinoma to their appropriate groups and referred to the considerable variation in the classifications recorded on the voting sheets. Where the opinion of experts is so divided it is not remarkable that statistics from different clinics on the results of treating cancer of the cervix at various stages are diverse, and this was the weakness that Dr. Heyman successfully exposed. On the social side the hospitality shown to members was almost overwhelming and few could take advantage of more than a selection of the entertainments offered if their attendance at the scientific sections was to be more than perfunctory. The congress will long be remembered with gratification by all those who attended it and especially by those coming from what was described as "the adjacent island of Great Britain."

## ANNOTATIONS

## INCREASING THE EFFECTIVENESS OF SEX HORMONES

THE discovery of David, Dingemans, Freud, and Laqueur, working in Amsterdam, that the action of testosterone can be increased by the simultaneous administration of an  $\alpha$ -substance, itself inactive, has led to some curious results. The Amsterdam investigators showed that the activating substance was of the nature of a fatty acid, and that androstenediol as well as testosterone could be "activated" by it. Subsequently Miescher, Wettstein, and Tschopp, in Basle, confirmed these results and then showed that the same effect could be produced by a wide range of fatty acids. These workers found testosterone in paraffin oil to be almost inactive, and it might be argued that co-substances, present in the oils commonly used as media for injection, are essential for the activity of the hormone. A paper we publish to-day throws further light on this problem. Dr. Deanesly and Dr. Parkes find that an increase in the effectiveness of androsterone and testosterone is obtained by increasing the volume of oil in which a given dose of the hormone is dissolved, and they also confirm the results of Miescher, Wettstein, and Tschopp with palmitic acid. They have failed, however, to find the increased effectiveness when the palmitic acid or the excess oil is given as a separate injection in a different part of the animal, and they incline to the belief that the effect depends on a more even absorption from the subcutaneous tissue, rather than on synergism between the hormone and the accessory substance at the site of action of the former. One has only to recall the great increase in effectiveness of androsterone when given as benzoate,<sup>1</sup> and the inefficiency of single injections of aqueous solutions of œstrone,<sup>2</sup> to realise the great differences caused in the degree of response by the manner in which a given dose becomes available to the animal.

The possibility of greatly increasing the effectiveness of comparatively scarce and expensive hormones is of general interest and the question arises whether the effect will be shown for the other known activities of the male hormones. It seems certain that  $\alpha$ -substance or fatty acid does not increase the activity of testosterone on the comb of the capon, but in the case of the œstrogenic<sup>3</sup> and progesterone-like<sup>4</sup> activities of certain male hormones an interesting field of experiment is opened up. At the present time œstrone and œstradiol are comparatively abundant substances in relation to their effective doses: hence, rendering more effective the œstrogenic action of male hormones is only of academic interest. Progesterone, on the other hand, is still very scarce, and comparatively large quantities are required to produce biological results. Until very recently the capacity to cause progestational proliferation has been supposed to be restricted to a particular diketone, progesterone; but the report by Klein and Parkes<sup>4</sup> disposes of this presumed specificity and makes it conceivable that more easily obtainable substitutes may be found and that the action of these might be intensified by methods similar to those discussed on p. 837.

## THE SURGICAL CONSCIENCE

CONSCIENCE has been defined, not without cynicism, as "the fear of being found out." A less ignoble, if slightly priggish, alternative might be "the fear of finding oneself out." Using the word in some such sense, Dr. Robert B. Greenough<sup>1</sup> emphasises the importance of a keen conscience to the surgeon in a world full of gullible persons obliged to entrust him with their lives and welfare. "Physicians and surgeons," says Dr. Greenough, "are not born supermen, they merely have to become so," and it is during the time of studentship that the surgical conscience is developed well or ill according to the ethical standards of the teaching staff. Once qualified the young surgeon is legally entitled to perform any operation of which he considers himself capable. His conscience is his only guide as to what he should or should not attempt. An ill-trained conscience may make him too bold or not bold enough. The apprentice system of surgical education, ideal where teacher and pupil loyally cooperate, may be ruined by the jealousy of the one or the arrogance of the other. In dealing with cases referred to him by the physician for operation, the surgeon's conscience must again be exercised. He is not to regard himself as the mere craftsman of the physician, but must take full responsibility for the patient and satisfy himself in every case that operation is warranted. Readers of *Punch* may remember the dialogue between a general practitioner and a surgeon. "What did you operate on old Jones for?" asks the general practitioner. "A hundred pounds," says the surgeon. "Yes, I know," says the general practitioner, "but what had he got?" "A hundred pounds" is the reply. There can be little, if any, truth in the gibe. Nevertheless some surgeons are casual in the matter of fees, being, no doubt, unduly generous in many cases and unduly exacting in a few. As Dr. Greenough wisely says, a good surgical conscience demands that the question of fees be frankly discussed beforehand if subsequent "unpleasantness" is to be avoided. In the surgeon's relations with professional colleagues, even in these days of keen competition, the "Golden Rule" is still an adequate guide to conduct.

## THE SIGNIFICANCE OF PSYCHOSIN

THE cerebroside, first described as constituents of fresh brain tissue, and subsequently found in the spleen and the kidney, yield on mild hydrolysis substances of great interest, and possibly of importance in the function of the brain. Derivatives from the brain have, for example, been shown to fix tetanus toxin; and this ready fixation obviously has an important bearing on the genesis and treatment of the disease. It is clearly important that our knowledge of these substances should be extended, and the substance psychosin, which is an amino-alcohol united to a sugar, has been, along with some other cerebroside derivatives, the subject of a detailed investigation by Drury and his co-workers.<sup>2</sup> It proves to be water-soluble and markedly surface-active; it is bactericidal in low concentrations, and capable of fixing bacterial toxins, agglutinating bacteria, precipitating normal serum, and hemolysing red cell suspensions. The bactericidal power is

<sup>1</sup> *Surg., Gyn., and Obst.*, Feb. 15th, 1936, p. 390.

<sup>2</sup> Drury, A. N., Miles, J. A. R., Platt, A. E., Plaut, G., Weil, H., and Hughes, A. R.: *Jour. Path. and Bact.*, 1936, xlii., 363.

dependent in part on the presence of the amino group, and is of the same order as that possessed by other surface-active substances like saponin. Two to four milligrammes of psychosin will fix 1000 minimal lethal doses (mouse) of tetanus toxin and about 50 minimal lethal doses (guinea-pig) of diphtheria toxin; the sugar and the amino groups appear essential for this action, and the toxins of Shiga's bacillus and *Olostridium welchii* are unaffected. The serum precipitation occurs at definite concentrations which fall within certain constant limits for the normal sera of different species. The phenomenon is not comparable with the straightforward precipitation by compounds such as ammonium chloride, but takes place in high serum dilutions and apparently depends on the change in charge of the serum particles as a result of absorption of the psychosin to the serum proteins. In rabbits this optimum concentration changes slightly after bleeding and considerably after poisoning with uranium nitrate or diphtheria toxin (these phenomena may have some relation to the changes in quantity and dispersion of the serum proteins that have been recently described in abnormal sera tested by specific serological precipitation and the ultra-centrifuge techniques). Psychosin readily lyses the red cells of many species of animals, including those of the human being. The hæmolysis is inhibited by the addition of serum.

These properties are probably dependent on the high degree of surface activity of the substance, which results in its ready absorption to a wide variety of other substances. Unfortunately this very activity prevents its detection as such in fresh tissue, since no agent which will disassociate it from its absorption compounds has yet been found. Pending that discovery, this work forms a very satisfactory groundwork for the biological study of the cerebroside derivatives.

#### PRE-OPERATIVE MEDITATION

NEATLY parodying the phrase "pre-operative medication" to which we have grown accustomed during the past decade, Dr. S. Kleinberg<sup>1</sup> pleads for more pre-operative meditation. Thirty years' experience of joint surgery has convinced him that joint tissues are no less resistant to infection than other tissues. Joint surgery, to be successful, requires merely "proper pre-operative cleansing of the patient's skin, the practice of aseptic methods, careful atraumatic expeditious technique, and, in addition, adequate pre-operative meditation." Planning ahead is essential. "The time to think," says Dr. Kleinberg, "is before and not during an operation." Especially is this desirable, and possible, in orthopædic surgery which is mostly elective and seldom of an emergency nature. When properly planned beforehand "an operation takes on the qualities of a musical symphony in which every element is a necessary part of the composition." One of the dangers of modern surgery is that the time spent in pre-operative meditation may be shortened whereas the time spent in operating may be lengthened. Dr. Kleinberg quotes the case of a surgeon who spent three hours fixing a fractured hip. During the operation a score of X ray photographs were taken. "During the whole of the procedure the patient was under a general anaesthetic and the wound was kept open. The risk of infection in such an instance is manifest." Dr. Kleinberg's phrase might be used in a much wider sense than merely that of planning the stages of an operation. It might with advantage

be borne in mind whenever any operative procedure is contemplated. General practitioners are familiar with the far-reaching and sometimes disastrous psychological effects of even successful operations. Pre-operative meditation should be cultivated by those who recommend operations as well as those who perform them.

#### MUMPS ORCHITIS

ALTHOUGH the orchitis of mumps, described by Hippocrates, is recognised as a serious complication that may result in sterility and possibly impotence, there is great diversity of opinion about its pathogenesis, incidence, prognosis, and treatment. Stengel,<sup>1</sup> in an elaborate study containing 120 references, accepts mumps as a virus disease, the portal of entry being "probably" the upper respiratory tract. He accepts, too, Trousseau's view that the orchitis is a metastasis, and that it proves a sympathy between the parotid gland and the genital organs. Trauma, chill, and exposure are not important factors, although they play, perhaps, contributory parts. An analysis of representative statistics shows that the average incidence of orchitis in those series comprising 1000 or more cases of mumps is 18.2 per cent. Stengel finds, however, that only 5 cases have been reported in boys under 12; it is commonest at puberty and during early manhood. It usually follows parotitis, but occasionally it seems to have been the first manifestation and "spontaneous" orchitis without parotitis has been recorded. (It may be suggested that, if the virus was the cause of the orchitis at all, missed solitary submaxillary or sublingual mumps may have been responsible.) Usually only one testis is involved; bilateral orchitis is much less common. Stengel considers that the temperature is the best guide to diagnosis and course. The parotid swelling and pyrexia having subsided, the temperature again rises and the patient experiences malaise and anxiety; there is local tenderness and swelling and, occasionally, fluctuation of one or other testis. Tenderness progresses to real pain, and by the third or fourth day of the orchitis the organ may be "enormously large" and the pain so intense that "large doses of morphine may not relieve it." The temperature may reach 105° F. with a parallel increase in the pulse-rate and, possibly, the respiratory rate. The testis becomes very hard and tense and continues thus for about six days, the whole attack lasting for ten days. Thereafter, swelling subsides and the temperature falls, usually by lysis, although true crisis is recorded. During the height of pyrexia, delirium, stupor, and even mania have been noted. Stengel says that there may often be meningitis and encephalomyelitis (of the aseptic type). The lesion is probably a parenchymatous sclerosis. As to whether the epididymis is first and always involved, or implicated later, or escapes entirely, there are divergent views. Subjectively, failure to recover completely from orchitis is indicated by diminished sexual power; objectively, by "atrophy"—a term very loosely employed. "Atrophy" may be relative or temporary, the organ regaining its normal size; it is estimated to occur in 40-60 per cent. of cases of mumps orchitis and is the result of pressure necrosis. Although only two cases of biologically proved sterility are on record, Stengel believes that there have been many others; femininity is stated to have followed double orchitis. The treatment of the condition is purely symptomatic; rest in bed with

<sup>1</sup>Med. Rec., Feb. 19th, 1936, p. 144.

<sup>1</sup>Stengel, A., Jr.: Amer. Jour. Med. Sci., March, 1936, p. 340.

elevation and suspension of the testis together with soothing local applications are among the most important measures. Injection of convalescent serum is recommended by some, incision for the relief of tension by others. Prophylaxis consists in measures to prevent the dissemination of mumps by contact spread, quarantine for 21 days being maintained; some regulations require isolation in separate cubicles. Convalescent mumps serum in the protection of contacts has met with "very fair success."

#### INTRASPINAL ALCOHOL FOR THE RELIEF OF PAIN IN MALIGNANT DISEASE

THE severe pain sometimes caused by malignant disease in its later stages cannot always be adequately relieved with opiates. Operations such as chordotomy and pelvic sympathectomy remove it in some cases, but these are major operations which throw a great strain on a patient who is often already exhausted by disease. It is good to learn therefore that a method of treatment has been devised which involves little strain and is often effective. It was Dogliotti who, in 1931, reported that pain could be relieved by the intraspinal (subarachnoid) injection of a small quantity (0.2 to 0.8 c.cm.) of absolute alcohol. He aimed at damaging the nerve-roots which, in the case under consideration, were conducting the painful impulses. The alcohol was therefore injected into the cerebro-spinal fluid with the patient lying in such a position that the nerve-roots to be dealt with lay at the uppermost part of the spinal canal. With the patient in this position the injected alcohol, because of its low specific gravity, rises to surround the nerve-roots concerned. Sensation may be slightly dulled, but weakness of the muscles seldom results, since the motor roots are more resistant to the effects of alcohol than are the posterior roots. Dogliotti's good results have been confirmed by several workers in America, and one of the most recent papers<sup>1</sup> on the subject comes from the Peter Bent Brigham Hospital, Boston. Good results have also been reported recently in our own columns.<sup>2</sup> In many of the reported cases severe pain has been abolished for several months by a single injection. A curious feature of some of them is that the pain is not relieved immediately, but continues unabated for two or three days before diminishing. All the authors emphasise the importance of giving a small injection (about 0.4 c.cm.) in the first place, because individual susceptibility to the alcohol injection varies greatly. The injection may be repeated in ten days' time if the first fails to give relief. Retention of urine is a serious complication which may follow the injection if too much alcohol is introduced.

While the intraspinal injection of alcohol requires no special skill, several details in technique are important. Hence it should not be attempted without study of the published records of those who have tried it.

#### VITAMINS AND IMMUNITY

A BATTLE over the anti-infective action of the vitamins is waged to and fro; but it is a pity there should be any battle. Prof. Rominger,<sup>3</sup> of Kiel University, sums up the situation in the following words: "Die Rolle, die Vitamine bei der Infektabwehr spielen, ist noch keineswegs klar erkannt und wird vielfach überschätzt"; which is in fact a

not unjust verdict. A specific action of the vitamins against infection has been sought and not found, except in the case of vitamin A. In rats deficiency of this vitamin leads to damage to epithelial tissues which is indisputably favourable to the penetration of infective organisms. In man it is seldom pushed to an extreme and opportunities for critical observation on any considerable series of cases have been few; but in Bloch's famous series of infant cases, in which the deprivation was severe, the disposition to broncho-pneumonia was conspicuous.

Unfortunately this question of the relation of vitamins to immunity is used in the political argument for and against prophylaxis against widespread malnutrition. It seems to us certain that malnutrition in any form, whether qualitative or quantitative, must aggravate the detrimental effects of infection, and whether it does so in a specific sense or otherwise is of less importance.

#### LOCALISATION OF SOUND

It seems unlikely that differences of apparent loudness between the response at the two ears have much to do with the accurate localisation of sounds under ordinary conditions of listening. This is at all events the considered opinion of Prof. F. C. Bartlett, F.R.S., in his introduction to the third report of a committee of the Medical Research Council.<sup>1</sup> People move their heads to help them to tell the direction of a sound, but because of the limited sensitivity of their binaural sense the ears are used only to provide the initial cues and then the listener peers about until he can see the object from which the noise is coming. If it is a familiar noise in a familiar place the localisation is more accurate, but sounds of very high or very low pitch are rarely located correctly, and a continuous sound is more difficult to place than one which is intermittent. As, moreover, our ears are normally used in the same horizontal plane, we possess a binaural sense of direction in bearing only, none in elevation. There are, it may be seen, two occasions of intense practical importance for exact localisation of sound when sight is not available: how can a listener locate the source of the sound emitted by a submarine when it is travelling under water; how can he tell the position and direction of flight of an aeroplane at night time? Science has come to his aid with a simple mechanical contrivance by which two enclosed airpaths lead one to the right and one to the left ear of the listener. Stethoscope tubes are connected to separate sound collectors, say five feet apart, which are so mounted as to be capable of being swung in any desired direction. The listener adjusts the whole apparatus so that he keeps the sound mid-way in his head. Provided the tubes are of equal length, the two sound collectors will now be in phase with respect to the waves coming from the source of sound. The human ears are capable of detecting a phase difference of half an inch in a sound wave (about 12 ft.). As they are about 6 in. apart it is not possible for them, unaided, to locate sound accurately to less than 5° in bearing. With the sound collectors 5 ft. apart the same phase difference will still be perceptible and the margin of error will have been reduced from 5° to 0.5°. For the detection of aircraft, four sound collectors are used, with one listener directing the apparatus in bearing and one in elevation. This mechanism would be of wider application were it not for the production of

auditory fatigue, better called experimental deafness, which almost certainly occurs in the central nervous system and not in the ear itself. If, for instance, one ear of a listener is submitted to intense stimulation for a short period the acuteness of hearing not only of that ear but also of the opposite ear is reduced for the time being. It is curious that this depression of hearing can be almost immediately dispelled if any sudden and unexpected stimulus of a different quality, such as a flash of light, is brought in. The phenomenon seems not to be one of fatigue in any exact sense but rather of the nature of a central inhibition. Both for theory and for practice the study of this attunement effect is of importance, and Mr. James's report contains the investigation and comparison of monaural and binaural attunement in which the share of central and peripheral factors is carefully worked out.

#### MENTAL DISTURBANCES ASSOCIATED WITH HYPERTENSION

THE mental states that accompany arterial hypertension have not been systematically studied. cursory reference to them, where arterio-sclerotic or uræmic phenomena are the main topic, is all that is to be found in text-books or monographs. This gap has been filled by Dr. Eduard Krapf of Buenos Aires.<sup>1</sup> The material of the psychiatric clinics of Munich and Cologne afforded him an opportunity, prior to the revolution in Germany, of making a large collection of cases which he had intended using for a descriptive study on Kraepelinian lines. The attempt to delimit a clinical group and incidentally narrow somewhat the problem of the involuntional psychoses led him, however, to the study of pathological bodily functions, and to a review of the whole question of constitutional and extrinsic causes, with hypertension as a paradigm. In the course of this further inquiry Dr. Krapf found himself departing from the strict Kraepelinian approach and coming nearer to the views which Kleist has urged with such force. This change of outlook did not materially alter his careful use of the data for, from either angle, the necessity for minute psychiatric as well as physical examination and description was obvious. Dr. Krapf has in fact compiled a clear and detailed picture of the range of mental symptoms accompanying hypertension. He describes four main forms: absences, twilight states, mood disorders, and change of personality. These varieties are not independent of each other, though they show differences in their mode of onset and their course. Many cases now loosely attributed to arterio-sclerosis or myocardial disease seem to belong properly to this group; and the discovery and separation of cases with hypertension from the ill-defined pre-senile psychoses would, it appears from this work, be clinically and pathologically profitable. Dr. Krapf thinks that general measures of diet and hygiene, the use of sedative drugs, and psychotherapy may do much in the way of prophylaxis, and that, when the condition is well established, measures for diminishing intracranial tension should be employed: it is to swelling of the brain that he attributes the confusional state that may develop in patients with "essential" hypertension. A general predisposition to high blood pressure and a more localised cerebral predisposition seemed, in Dr. Krapf's clinical material, to be potent factors in the causation. The significance of the findings in this

study, when applied to psychiatry generally, is considerable, as may be seen in Dr. Krapf's final review of the relation of the syndrome to other morbid types of reaction.

#### EPILEPSY AND CORTICAL RHYTHM

A NEW and promising line of attack upon the problem of epilepsy is described by Dr. William G. Lennox in a paper entitled the Physiological Pathogenesis of Epilepsy,<sup>1</sup> which he read before the International Neurological Congress in London last year. Dr. Lennox has been engaged for many years in investigating epilepsy by physiological and biochemical methods. In this paper, the twentieth of a series on epilepsy, he first describes some observations which negative once-popular theories of the mode of production of epileptic attacks. He brings forward evidence that an attack is not preceded by a diminution in the volume of the cerebral blood flow nor of the oxygen tension of the blood going to or coming from the brain. Complete unconsciousness caused by syncope artificially induced was rarely effective in precipitating an attack in epileptic patients.

During recent years a method of recording electrical changes in the cerebral cortex has been devised, and it is already clear that we may expect this new technique to throw as much light upon disturbances of cortical function as electrocardiography has done upon abnormalities of the heart-rate and rhythm. Dr. Lennox and his collaborators, Dr. Frederic Gibbs and Dr. Hallowell Davis, have obtained records of the electrical potentials from the brains of 21 patients during hundreds of seizures. They have found that an attack of petit mal is invariably accompanied by a burst of action potentials much larger and less frequent than those normally found in the patient. Such patients, however, even when they are free from any objective or subjective evidence of a seizure, may show similar small alterations in potential which are regarded as subthreshold seizures. The nature of these abnormal electrical discharges occurring in the brain must, at present, be a matter of speculation. Lennox suggests that in normal activity there are many clusters of neuronal cells discharging, not in unison, but in harmony. The usual Berger rhythm of 10 to 20 discharges a second is explained as a mosaic of the activity of many centres. In an attack of petit mal many waves become one. The large wave represents a synchronisation of various discharging cell clusters. In Lennox's graphic words, "the harmony of the symphony orchestra has become a single note. The representative constitutional government has become a totalitarian state." The cause of this pathological unanimity has yet to be found, but it is already clear that the search for it will lead to one of the most fundamental of neurological problems, the rôle of time in neural function.

At a meeting of the Royal College of Physicians of London last Monday Lord Dawson of Penn was re-elected president.

On April 1st the Lord Mayor of London presided at the Mansion House over the first meeting of the general committee formed in connexion with the proposed memorial to King George. A "philanthropic scheme" committee was elected, whose 26 members included Lord Dawson, Lord Horder, Lord Moynihan, the lord provosts of Edinburgh and Glasgow, and the lord mayors of Liverpool, Cardiff, York, and Newcastle.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

### **XCVI.—PROGNOSIS IN CEREBRAL CONCUSSION AND CONTUSION**

THE common effects of head injury fall naturally into two groups. The outstanding feature of the first group is immediate interruption of consciousness. This may range in degree from a state of automatism to one of stupor, and in duration from minutes to days. It leaves behind it a gap in the memory by which the duration of unconsciousness is conveniently measured. This phase (which in its shorter forms is usually called concussion) presents a great variety of symptoms—positive as well as negative—which deserve closer study than they have received, especially in relation to the occurrence of sequelæ.

The second group includes symptoms such as headache, giddiness, mental change, and insomnia. These may appear after consciousness has been regained, or they may occur without any initial disturbance of consciousness; they may follow the injury at once, or after a latent interval of hours or days. Though they show constantly a tendency to improvement and eventual recovery, sometimes and in some degree symptoms of this kind may persist indefinitely. Their character implies the persistence of some morbid state, which is commonly assumed to represent an unresolved cerebral contusion.

These two groups of symptoms together represent the common sequelæ of head injury, and run their course independently of such complicating features as fracture of the skull, epidural, subdural, or sub-arachnoid hæmorrhage. They offer a field still rich in opportunity for detailed observation and correlation of early symptoms with end-results.

#### **Immediate Prognosis**

##### IN SEVERE INJURIES

*Prognosis as to Life.*—In the majority of fatal cases death occurs within the first twenty-four hours. During the succeeding twenty-four hours the risk is still considerable. Post-mortem examination reveals extensive contusion and laceration of the brain. These patients when first seen are, as a rule, comatose. They do not respond by movement or grimace to painful stimulation. The pupils are dilated and often unresponsive to light, and the corneal reflex may be absent. The limbs are flaccid and motionless, and the breathing stertorous. The plantar responses are usually extensor. The pulse-rate is variable. A rapid, feeble pulse persisting is of bad import, but a normal rate may be found in cases which are rapidly fatal. The temperature in the first instance is subnormal—in the region of 96°. Subsequently it is apt, either to remain at the subnormal level, or to rise rapidly to 104°, 105°, or even higher.

In this group of the most severely injured the patient who is going to recover will, as a rule, show a definite improvement within the first twenty-four hours. Response to painful stimulation returns, spontaneous movements of the limbs appear, the pupils become smaller and react to light, the pulse becomes fuller, and the temperature, rising to a moderate height (101° to 103°), remains about this level. In the phase of recovery a slow pulse-rate (56 to 60) is often observed and may persist for several

days. After the first forty-eight hours death from cerebral contusion is uncommon, and the small mortality-rate which persists is mainly due to such complications as pneumonia and meningitis, the latter resulting from a fracture of the base running into the middle ear or one of the nasal sinuses. Some patients, however, do succumb without any cause other than cerebral contusion after remaining in a state of coma or stupor for a week or more. As a rule in such cases the temperature shows a climbing trend.

*Traumatic Stupor and Delirium.*—The patient who survives frequently passes through a phase of stupor and delirium lasting several days before he becomes mentally clear. Apart from an extensor plantar response on one or both sides, he usually presents no abnormal physical signs. What will be the outcome of this phase? We can at least affirm that the state of confusion will pass. It rarely exceeds three weeks in duration, but I have notes of three cases in which a state of severe traumatic delirium persisted for three, seven, and nine months respectively with eventual recovery. While it persists the confusion itself conceals effects of the injury which may be of a more lasting and, therefore, of a more serious nature. Sometimes the presence of hemiparetic signs, or the detection of dysphasia, during this stage may make it clear that a coarse lesion of the brain is present. As a rule prognosis as to the next stage must wait until the patient is clear. On the whole, the longer the duration of traumatic stupor the greater is the likelihood of troublesome after-symptoms, but there are exceptions to this rule. Young persons, especially, may return to full consciousness at the end even of two or three weeks, and neither show nor admit any further symptoms.

*The Aftermath.*—With the return of consciousness the patient may exhibit changes in disposition or defective memory, of which he himself is unaware, or of which he may complain. Impairment of the intellectual functions is, on the whole, commoner and more persistent in patients past middle age. Children, on the other hand, are more likely to exhibit striking changes in character and disposition. Such mental traces of organic damage are slow to improve, but usually end in recovery. Most of the symptoms in this stage, however, are subjective, and it is, therefore, the complaints of the patient which afford the main facts available for prognosis. Of what degree of mental and physical activity is he capable without symptoms, such as headache, giddiness, excessive fatigue, or insomnia? This question can only be answered by separate experiment in each case. If under conditions of absolute rest such symptoms are present, convalescence must be slow and the disability will be of long duration. Even if at first there is freedom from symptoms, it is not safe to predict an uneventful recovery until the patient has progressed symptom-free through graduated stages to his normal level of mental and physical activity. If in the course of this experimental progress symptoms develop, the stage of activity at which they occur will provide an indication of the prognosis. The answer, then, in this phase to such questions as: "Has there been lasting damage to the brain?" and "How long will it be before he gets well?" must often be given in such terms as: "We cannot tell until we have seen

how much the brain will stand without complaint." We may safely add that complete recovery is the rule even though the symptoms at first may be severe and improvement slow. If evidence of a coarse lesion is present from the first, such as hemiparesis or dysphasia, the prognosis is naturally uncertain, but the majority of patients who survive with such symptoms make a satisfactory recovery. Dysphasia is the more serious symptom.

"Neurasthenic" symptoms—*anxiety, depression, preoccupation with self, increased liability to mental and bodily fatigue, and head discomforts of the functional type*—constitute an important part of the aftermath of head injuries, both severe and mild, but are more likely to occur after the former. They are often precipitated or aggravated by anxiety over compensation. Symptoms of this kind are not likely to be observed in tough-minded persons. Their frequency is proportionate to that of similar illness in the family, and personal, history of the patient. Knowledge of his constitution in these terms may sometimes explain why it is that one individual may suffer much more than another after injuries of comparable severity.

#### MILD INJURIES

A man suffers a blow on the head at football, continues with the game in a state of traumatic automatism, and is later shown to have a half-hour gap in his memory. Such is a typical mild head injury. In nine cases out of ten there are probably no after-symptoms more serious than a headache which is gone next day. In the tenth a persistent and even disabling liability to headache may supervene, perhaps associated with giddiness, insomnia, and fatigue. The more severe and prolonged the disturbance of consciousness, the more likely on the whole are sequelæ, but effects of this kind may follow a head injury without any disturbance of consciousness. In either case these effects may directly follow the injury, or may appear after an interval, sometimes amounting to several days. Once such symptoms have appeared, their prognosis (which depends a good deal upon early recognition and proper treatment) must be gauged by the methods already described in connexion with the aftermath of severe injuries.

#### MENINGEAL HÆMORRHAGE

Meningeal hæmorrhage, whether epidural or subdural, is more likely to occur (and much more difficult to detect) in the severe injuries than in the mild. A chronic subdural hæmatoma may develop after the mildest injury, especially in aged persons. In such cases there may be an interval of weeks during which recovery may appear complete. The condition is an extremely rare one, but the complete prognosis after any head injury, especially in old people, would include a note of this possibility.

### Ultimate Prognosis

#### DURATION OF SYMPTOMS

Symptoms of the kind already referred to under the aftermath of severe injuries may, as we have seen, be absent even after prolonged traumatic stupor; they may occur without disturbance of consciousness. As a rule, however, their severity and duration are directly related to the duration of unconsciousness. Of the common symptoms giddiness is usually the earliest to disappear; defective memory and changes in disposition are slow to improve, as also are symptoms of the neurasthenic group. Of all symptoms the liability to traumatic headache—intermittent, localised, and often severe—

is the most persistent, and is more likely than the others to be permanent. The duration of all these symptoms depends a good deal upon the efficacy of treatment in the earlier stages. Recovery is quicker among those whose means enable them to obtain a quiet and smoothly graduated convalescence.

The age of the patient also is an important factor. Over the age of 45 the process of recovery is slower. W. Ritchie Russell's paper on this subject (*Edin. Med. Jour.*, 1934, xli., 129) is an important source of information. Taking a series of 200 patients admitted to hospital with loss of consciousness—a group therefore from which a great many of the milder cases of head injury are excluded—he found 40 per cent. free from symptoms at the end of two months. The percentage of those recovered in each age-group showed little variation, except that of the patients over forty, only 23 per cent. were recovered at this time, and of those over fifty none.

Of the 120 patients whose symptoms persisted longer than two months 66 per cent. still had symptoms at the end of eighteen months. Many of the symptoms, however, were slight and did not interfere appreciably even with heavy manual labour.

#### DURATION OF DISABILITY

The main factors which influence prognosis in this respect are, in order of importance, the severity of the injury as measured by the duration of unconsciousness, the age of the patient, the question of compensation, and the nature of his occupation. These may conveniently be considered in the reverse order.

*Nature of Occupation.*—Headache is the most persistent of the common symptoms and, being aggravated by physical effort, is likely to remain a source of disability to the manual worker after other symptoms have disappeared.

*Compensation.*—Anxiety over unsettled compensation, or a sense of injustice after settlement, are important causes of prolonged disability. The latter may result in some degree of permanent invalidism. Of Russell's 200 patients, 139 were working men or women. Among these 30 per cent. of the compensation cases reported unfit for full work eighteen months after the accident, whereas the figure for the non-compensation cases was only 9 per cent. In the non-compensation group 83 per cent. of the patients had returned to full work within six months of the accident.

*Age.*—After middle age risk of permanent incapacity in some degree is considerable, especially in the case of manual workers. In the group of non-compensation cases just mentioned, of the patients who were over fifty years of age, 45 per cent. remained unfit for full work at the end of eighteen months. The prognosis in the case of sedentary workers is certainly better than these figures would suggest.

*Duration of Unconsciousness.*—There is a direct relationship between this and the duration of disability, which is best seen when the factors of age and compensation are excluded. The following estimates are based mainly upon Russell's figures. In persons under the age of forty, if no compensation question is present, when the injury is one which does not involve more than a few minutes loss of consciousness, disability lasting more than a few days is uncommon. After a period of unconsciousness up to one hour, nineteen persons out of twenty will be back at full work within two months. If stupor persists longer than 24 hours the chances are against the patient being fit for work within two months, but eight out of ten patients will be able to return to full work within six months of the injury.

Such are the considerations which afford a guide to the *likely* duration of disability. Actually in the individual case the question can only be settled by trial and observation. In non-compensation cases if a manual labourer has not returned to full work at the end of six months it is on the whole unlikely that he will ever do so.

#### TRAUMATIC EPILEPSY

As a late complication of closed injuries epilepsy is uncommon but important. Its rate of incidence is

difficult to compute, but the risk appears to be greatest in cases which show in the early stages signs of focal injury, prolonged traumatic stupor, or fracture of the vault; and in the later stages, persistent headache and mental changes of the organic type. The interval between the injury and the first attack is commonly about a year, but may be much longer.

Hospital, Queen-square.

## SPECIAL ARTICLES

### TUBERCULOSIS ASSOCIATION

THE provincial meeting of this association was held in Cambridge from April 2nd to 4th. The subject for discussion at the first session was

#### Dispensary Organisation

The opening paper was read by Dr. R. H. HAZEMANN (médecin inspecteur, préfecture de la Seine), who gave a critical review of the dispensary organisation in France, with special reference to his own administrative county. The organisation of the anti-tuberculosis campaign was practically autonomous, and was based on the *Dispensaire d'hygiène sociale et de préservation antituberculeuse*, to which was added a scheme of appropriate institutions for the sick, for those infected, and for healthy contacts, the main effort being directed to the welfare of children. The treatment of sick patients was restricted to private medical practitioners and to institutions. In France the dispensary doctors never visited patients at home, and the only treatment practised at the dispensary was pneumothorax refills. No treatment by ultra-violet light or tuberculin, and no dental or orthopaedic treatment was carried out. The dispensary, except as regarded treatment, was open to all, irrespective of income, with the full consent of the medical syndicates; and all its benefits were obtained free of cost. Of the 60 dispensaries in the Seine, which included Paris with its 2,891,000 inhabitants, 51 belonged to the public health office, 2 to the assistance publique (an official organisation controlling almost all the hospital beds in the Seine), and the remainder to private bodies. Each dispensary dealt with a particular district in which it was legally bound: (a) to detect and diagnose cases of tuberculosis; (b) to detect and deal with contacts; (c) to facilitate institutional treatment of patients; (d) to carry out home prophylaxis, particularly with regard to children. Contacts underwent the same investigation as other patients—physical, X ray, and sputum examinations, and a tuberculin test in children. Child contacts remained registered indefinitely after the death of the patient; adults were discharged after a year's observation if free from disease. Attendance at the dispensaries for examination was encouraged by such "means of persuasion" as education, and the distribution of meat and milk coupons.

Dr. M. R. HEYNSIUS VAN DEN BERG (director, tuberculosis service, Amsterdam), said that the anti-tuberculosis campaign in Holland was carried out by voluntary organisations subsidised by the State, province, or municipality, their activities being under the supervision of the Government inspector of health. The national association undertook general propaganda, the training of visiting

nurses, tuberculosis research, &c. The 11 provincial societies in the country ran the dispensaries in each province. The task of the local societies, of which there were between 800 and 900, was to carry out the prophylactic and social measures prescribed by the tuberculosis officer, while they were also in charge of the expenses for institutional treatment. In the larger cities, indeed, the local societies were specifically tuberculosis institutions with specially trained tuberculosis nurses. There was in Holland no compulsory notification, and at the dispensaries no treatment whatever was given. Refills for artificial pneumothorax must be given at the nearest hospital. In Amsterdam the work was strictly centralised, so that everything the patient needed could be obtained only through the dispensary. Admission to hospitals and sanatoria was, in Amsterdam, arranged by the dispensary, and after discharge the patients were supervised from there. Whenever possible, an infectious patient was hospitalised, which could be done in 80 per cent. of the newly registered open cases. Removal of the children from their homes, as in the *Œuvre Grancher*, was hardly ever resorted to. Infants in contact with open cases were vaccinated with BCG. The death-rate from pulmonary tuberculosis in Amsterdam was 3.4 per 10,000, and from all forms of tuberculosis, 4.34.

Dr. N. TATTERSALL (Leeds) pointed out that dispensary organisation could not be discussed as a separate entity; it was only one part of the complete tuberculosis scheme, and apart from its indispensable complement—institution beds—would be but a feeble weapon. Further, the problem to be tackled varied widely according to the area served. The speaker went on to sketch the organisation of the Leeds dispensary, as being fairly typical of the first group. There was one large central dispensary, fully equipped for diagnostic work and special treatment with X ray, artificial sunlight, orthopaedic and dental facilities; the main city sanatorium was only some three miles away and large general hospitals close at hand. The whole scheme was thus compact and made coöperation easy between dispensary and institutions. All attendances except those of new patients were made by appointment. One day was largely reserved for contact examinations, and two afternoon sessions were devoted to A.P. refills. Two evening sessions weekly were devoted to workers, and Saturday mornings devoted to school-children. Close coöperation with many agencies was an essential part of dispensary work. The home rather than the patient was the unit on which they concentrated, and continuous close touch was maintained with the homes of all patients. The most important of the many "lines of communication" was with the general practitioners, and coöperation with school medical officers was also valuable. Although the mortality statistics were encouraging

and even flattering, the real test of antituberculosis organisation would be the establishment of morbidity statistics.

At the next session Dr. RUSSELL J. REYNOLDS, after describing his cineradiographic apparatus for recording the functioning of active organs, showed two films, the first reel dealing with general thoracic work—chiefly cardiac conditions—and the second with the movements of the lungs and diaphragm in various stages of pulmonary disease and under different conditions, such as collapse, after phrenicectomy, with pleural effusion, after lipiodol injections, &c. The films were followed with the greatest interest, the value of this method of permanent record being fully appreciated.

On April 3rd the meetings were held jointly with the International After-Care Committee of the *Union internationale contre la tuberculose*. At the first session a paper by Sir PENDRILL VARLIER-JONES (Papworth) was read, in his absence through indisposition, in which he reiterated his belief that treatment and after-care must be regarded as one and indivisible. He deprecated the deep-seated idea that while clinical treatment was important and worthy of State support, after-care was an unimportant frill which might with propriety be left to private or public charity. If this viewpoint were changed, local authorities and other public bodies would be as willing to contribute towards the permanent settlement of their cases as they were to provide for their treatment. We might then get some idea of the real potentialities of village settlements which at present could only be estimated. So long as after-care remained the Cinderella of the tuberculosis schemes of the nations, just so long would there be a tuberculosis problem.

#### Capacity for Work in Pulmonary Tuberculosis

Dr. MAURICE DAVIDSON (London), opening a discussion, reminded his audience that the word "work" applied to all forms of expenditure of energy, and he went on to stress the importance of various forms of mental and emotional energy in relation to pulmonary tuberculosis. In estimating the capacity for work of a tuberculous person he thought that too little emphasis was laid on the significance of purely nervous katabolic energy, apart from that of physical exertion. In regard to the incidence of active disease of the "young adult" type in females, the factor of psychological energy, which played no small part in the life of young women to-day, was one which ought to be taken very much into account, as all experienced tuberculosis officers would agree. Their conception of the meaning of work in this connexion was often too one-sided, and these broader principles should underlie their advice to patients in regard to a choice of future occupations. Dr Davidson laid great emphasis on the importance of frequent radiological examinations as a guide to the behaviour of tuberculous lesions in the lung, pointing out the value of this (sometimes the only) evidence of the extension of disease.

Dr. L. B. STOTT (Papworth) said that tuberculosis could be an acute disease, and, like any other acute general infection, have a pneumonic stage in which the patient would obviously be incapacitated. On the other hand, the patient with a healed primary focus in the lung was of undisturbed working capacity; though during the establishment of the focus he might have been completely incapacitated or working in spite of toxæmia. In the life history of every case

of tuberculosis there were doubtless periods during focal reactions when the capacity for work stood at nil; and in any estimation of how far a tuberculous patient was limited in output during the intervals between exacerbations, the decision as to capacity for work must be made in complete ignorance of the future. The physical signs held a significance as to present capacity alone. Estimations of the capacity had to be made (a) on anatomical indications, including location and extent of the tuberculous lesion; and (b) on physiological capacity, or response to effort. For practical purposes, the examination of the urine—especially ratio of free acid to combined acid—was one of the most useful physiological guides. Another important point was the effect of tuberculosis upon the physiological efficiency of the ductless glands. Perhaps, however, the most important factor in the assessment of the capacity for work was a consideration of the psychological state. The object of all treatment was to restore the working capacity, and there could be no doubt that purposeful routine had its reaction on every organ.

#### After-care

Prof. Dr. VON WEIZSÆCKER (Heidelberg) said that the after-care movement seemed to him to be the result of a conception of medicine which affected not only the tuberculosis question, but the whole field of therapy; it appeared to be the outcome of a system of social medicine and the recognition of the social diseases. The inquiry was now not only: "What does the patient need?" but "How does the patient live?" They wanted to know not only which remedies would relieve his symptoms, but also how society should behave towards the sick man. Social therapy ordained not only that the sick man or ex-patient should live, but that he should live as an ordinary human being. In many cases there was a gap between hospital and employment which neither practitioner nor dispensary physician could fill. An example of this was in a case of concussion. Returning home after discharge from hospital the patient would be still unable to make a complete recovery, because he was still unfit for normal employment. He would almost inevitably drift into a state of worry and boredom, and his health would deteriorate rapidly. This they called in Germany the "secondary disease." It used to be treated in a neurological clinic as a neurosis, but although the predisposing factor was psychological, psychotherapy was not the most suitable treatment, since the patients in most cases were not constitutional psychopaths or neurotics, their secondary symptoms having developed under a sense of insecurity and futility, coupled with fatigue of the will-power. This factor of interruption of the placid stream of social existence was now recognised as the origin of the secondary symptoms. It could largely be obviated by gradually giving the stimulus of work at a much earlier point—e.g., in the case of concussion, before the patient had left the hospital. In regard to social insurance as a means of obviating this so-called secondary disease, Dr. Weizsæcker made three suggestions: (1) The system of special insurance rates for special injuries, and especially for accidents, had great disadvantages from the medical point of view. National health would benefit by a comprehensive scheme of insurance; (2) it was also a disadvantage when a system of insurance was based upon the quantitative assessment of injury. Benefits should rather be assessed according to financial needs, or, better still, by the provision of suitable

employment rather than purely financial assistance; (3) the legal administration of insurance was not as good as the practical organisation of after-care, national health, and supply of work. The ideal was re-education and re-adaptation to work.

Dr. E. BACHMANN, Secretary, International After-Care Committee, said that it was essential that when treatment, training, and colonisation were carried out in different localities and under different organisation, the whole should operate as a single unit under medical control. They must not forget that they were dealing with tuberculous patients in whom at any time reactivation and relapse might occur. For this reason experiments in after-care were to be deprecated which were independent of sanatoria, antituberculosis organisations, and dispensaries. It must always be borne in mind that the essential element of the whole structure was the sanatorium or similar institution, with which the other departments were indissolubly united. Sanatorium training centre and settlement might together form a single unit, or they might be situated in different areas, each under its own medical superintendent, but in every case close coöperation was indispensable. A training centre independent of a sanatorium must perforce provide its own clinical and therapeutic wards for the treatment of patients who prove unfit for work. In many places this coöperation was absent, although it was the basic principle of the successful solution of the whole problem. Dr. Bachmann then went on to describe in detail the scheme which had been adopted by the Anti-Tuberculosis League in Switzerland for the Canton of Zurich. This experiment differed from that of the principal Dutch institutions, in that the training was separate and under a different board of control from that of the sanatorium. In spite of this division, close contact between the two had to be maintained in view of the constant necessary interchange of patients fit for training and those who, owing to relapse or unsuitability, must return to the sanatorium. Although this coöperation was continually being increased, the training centre had found it desirable to establish a small therapeutic unit for those inmates who could presumably begin to work fairly soon, and for those in whom the arrest of disease had been temporarily interrupted by employment. In any case, when sanatorium and training centre were not in the same area, instruction regarding the aim and object of training should be given at the sanatorium; otherwise the patient would immediately get the idea that he might just as well go home and seek employment under more or less sheltered conditions.

This paper was followed by a long discussion. Dr. N. BARDSWELL commented on the difficulty of deciding whether or when a patient would be fit for work. He found himself instinctively depending on first impressions. One might be occasionally misguided by the appearance of a patient straight from a sanatorium who might look better than he was; but he had learnt to discount this. He judged also largely by the character of the primary lesions, and by the response the patient had made to treatment. He attached also great importance to negative sputum reports over a period of six months. The question of A.P. complicated the issue, by disguising the condition; but any patient whose disease was arrested, whether by rest or by mechanical means, should in his opinion be allowed to return to work. The factor of age was of importance, also that of the nature of the work.

In the afternoon excursions were arranged to Papworth and to the Strangways Research Laboratory at Cherry Hinton. At Papworth other papers on schemes for after-care were read by Dr. BRONKHORST (Holland) and Dr. PATTISON (Potts Memorial Hospital, New York).

### Chronic Miliary Tuberculosis

On April 4th Prof. L. SAYÉ (Barcelona), reading a paper on this subject, said that the clinical study of this condition led to the following classification: (1) chronic miliary tuberculosis of primary infection; and (2) chronic miliary tuberculosis of reinfection—(a) chronic generalised tuberculosis, (b) chronic *granulie*, (c) localised forms of hæmatogenous origin, and (d) non-apparent forms. In (1) the clinical onset was usually unrecognised or insidious, or associated with the symptoms of primary infection, showing high pyrexia and signs of broncho-pneumonia. In the generalised form death usually took place from meningitis. The recent work on primary infection, which had shown the frequency with which this syndrome is found in adolescents and young adults, had extended the clinical scope of the primary infection type of chronic miliary tuberculosis. Further clinical study was needed to define its limits and characteristics at these age limits. With regard to (2) the speaker examining radiologically 1176 students at Barcelona University had discovered in them all four varieties. The second variety, showing disseminated discrete nodules, were found in 5.6 per cent., and they were being followed up in order to ascertain whether these lesions played a pathogenic rôle in the development of phthisis, or whether they should be considered merely as relatively recent remains of primary infection. Of the students with unsuspected lesions or with lesions associated with very slight symptoms, more than one-third showed lesions of the hæmatogenous type. In the first type, chronic generalised tuberculosis, the pulmonary involvement which the morbid anatomists nearly always found in the patients, did not give rise to clinical signs until in the advanced stage. In other cases extrapulmonary and pulmonary symptoms appeared at the same time, but the latter remained most obvious in most of the patients. Radiography of the lungs showed a chronic miliary picture. Further work might lead to the recognition of a hæmatogenous basis in certain unilateral lesions, and the systematic examination of the lungs in cases of chronic generalised tuberculosis should assist in their study.

The remainder of the session was taken up by the presentation of cases for diagnosis by Drs. S. VERE PEARSON and G. T. HEBERT and Mr. H. P. NELSON.

### X RAY DEVELOPMENT ON THE CONTINENT

IN the course of an address to the medical section at British Industries House Mr. C. Morgan Davies, of the engineering department of King's College Hospital, gave some account of radiological development in northern Europe, based on a recent visit to 20 hospitals and clinics in Belgium, Germany, and Holland, and some factories specialising in hospital X ray apparatus. Dr. Graham Hodgson presided. Mr. Davies was impressed, he said, by the rapid developments in electro-technics in hospital work. Short-wave generators for electrical treatment, high-

frequency spark cutters for operative purposes, numerous diagnostic aids, the X ray kymograph, cine-radiography, the tomograph, and many other devices are in some cases in regular use. The German hospitals also employ a larger number of radiographers and other medical auxiliaries than we do in this country and train them for a longer period.

The tendency, noticeable in this country, to separate X ray diagnosis and therapy appears to be absent in Germany and Holland, where the services are under one director. In the newer hospitals it is customary to provide greater privacy for the patient by the installation of one or, at most, two pieces of apparatus in a room or cubicle. One important difference between British and continental diagnostic lay-out is in the machine control. On the continent the switch-table controlling the generator is always a fixture, being installed in a control cabin with observation windows of lead glass and dark blinds, so that the operator may observe in three separate rooms, of which one may be in darkness for screening. Continental workers express surprise at our less scrupulous precautions to guard against stray radiation. In hospitals the generators themselves are housed in separate rooms, it may be on the level of the operating rooms, above or below them, controlled by switchgear housed in the cabins. The all-metal cabinet, a standard production of the factories, is however used in private installations and the smaller clinics. The examination rooms contain nothing other than the diagnostic apparatus, the tubes, and shock-proof cables. All installations visited were completely shock-proof; bare high-tension systems are rarely seen. The first shock-proof cable, installed at Heidelberg in 1928, is still in use and giving no trouble. There are several methods of connecting the transforming units to the X ray tubes; some of these indicate the confidence placed by the makers in their cables. In one installation in Hamburg the transformers are connected to junction boxes by means of paper-insulated lead-covered cables buried in the plaster of the walls; some of these cables carry 200 kilovolts. In another installation in Berlin the transformers are in the basement, the high-tension distribution gear in a loft above the operating rooms, the connexions being made by lead-covered conductors which run in cavities in the walls. Metal-covered wall ducts are common and the cable runs may be very long, sometimes 20 metres or more per pole. The three-phase unit is not found inferior to the single-phase in the production of contrasting radiograms. The rotating anode tube is firmly established; there are at least 700 installed in Germany. In the diagnostic installations there are refinements for chest and stomach work. All the controls for screening, radiography, diaphragms, different coloured room lights, &c., are grouped to the left of the screen, handy for the operator. Foot switches are rarely seen. This equipment, observed through periods of intensive activity, appeared to meet every requirement with a minimum of trouble or effort. It combines minimum weight with great strength. Apparatus known as the tomograph and the introscope, for producing pictures of sections or layers of the human body, are in routine use at Berlin, Bonn, Heidelberg, and Rohrbach.

Activity in X ray therapy is apparent everywhere. Here again the tendency is to limit the number of treatment couches to one per room. At the Louvain hospital the installation consists of eight tubes, four working at 200 kv. and four at 400 kv., the latter energised from cascade condenser units with gas-filled valves. Although these tubes are not shock-

proof as generally understood, it is impossible for a patient to come into contact with high-tension conductors while undergoing treatment. One room housing two tubes has been designed for an ultimate tension of a million volts, with 5 cm. of lead incorporated in the walls. The "cannons" installed some years ago in the Holfelder clinic at Frankfurt are all in daily use and giving satisfaction. It is well known that Germany has comparatively small supplies of radium, which probably accounts for the development of short-distance X ray therapy equipment seen in many hospitals and developed by Prof. Chaoul of Berlin. This therapy, which has much in common with radium treatment, consists of the application of a high dose carefully localised. The radiation is generated in a special tube having one electrode earthed, the anode in the case of the Chaoul tube, the cathode in the case of the tube used by Van der Plaats at Eindhoven. The apparatus is simple and comparatively inexpensive; it will permit, it is stated, of a far greater number of treatments than is possible with radium, having regard to the quantities available and the ease of application.

In thanking Mr. Davies for his lecture, which was followed by an interesting discussion, Dr. Graham Hodgson endorsed his plea for closer collaboration between the radiologist, the physicist, and the engineer, and he observed that the allocation of diagnostic and therapy work to two members of the staff in voluntary hospitals was probably due to the fact that one man is unable to give voluntarily the time necessary for the two departments.

## MEDICINE AND THE LAW

### Irish Free State Law against Contraceptives

THE sale of contraceptives, or the advertisement or importation of them for sale, became a statutory offence in the Irish Free State last year. What seems to have been the first prosecution under the new law is reported from Waterford. A firm of pharmaceutical chemists was summoned for having imported, or attempted to import, a quantity of quinine pessaries. An official of the Free State customs, during the usual examination of imported goods, found these commodities and communicated by telephone with the defendant firm to whom they were consigned. According to the prosecution, a representative of the firm admitted that the goods were contraceptives and, when warned that they were liable to confiscation, answered that the customs authorities could keep them. The goods were then sent to Dublin to be destroyed. The definition of contraceptives in the Free State statute is "any appliance, instrument, drug, preparation or thing designed, prepared or intended to prevent pregnancy resulting from sexual intercourse between human beings." A customs official seems to have been asked whether the telephone conversation did not include a statement that the commodities could have been used for dogs or cattle. A medical witness who described the nature and properties of quinine is reported to have said that, in the course of his experience and training, he had never heard of quinine pessaries being advocated or suggested for use in any obstetrical or gynaecological condition. A managing director of the defendants, producing the firm's ledgers, read therefrom four instances in which medical officers had prescribed these pessaries; he contended that the prescriptions did not contemplate

their use as contraceptives. The prosecution conceded that the firm was well managed and of high repute. The district justice, observing that it was a difficult section of the Act, dismissed the summons under the Probation of Offenders Act.

The Irish Free State Act of last year under which this prosecution was launched contains, apart from Section 17, several fresh provisions against immorality. There are sections for the suppression of brothels and of prostitution, and there are various amendments of the Criminal Law Amendment Act, 1885, which is still the basis of the law of offences against women and girls in the Free State.

### Murder Conviction Quashed on Fresh Medical Evidence

Last week in *R. v. Harding* the Court of Criminal Appeal did two unusual things; it allowed an appeal against a conviction for murder and it permitted fresh evidence to be called on appeal. Mrs. Harding, aged 31, was the mother of four children; the youngest was a baby six months old. The case for the Crown at the trial was that she deliberately threw her child into the canal. Her own story was that she had been sitting on a seat, nursing her baby, when she felt faint and giddy; that she rose and walked a little way and fainted on the bank; and that, when she came to, she saw the baby in the water. No one else was present who could say what happened. There was some other evidence which told against Mrs. Harding—for instance, her subsequent conduct after she knew the child was in the water; but the main point in the case was the rapidity and the degree of the immersion. A medical witness, called for the prosecution, described the results of the post-mortem examination of the child. No medical witness was called by the defence. On appeal, Mrs. Harding's counsel obtained leave to call another medical witness. This was Dr. J. C. M. Matheson, medical officer and governor of Holloway Prison. He had been present in his official capacity during the trial. He now told the court that the post-mortem condition described was compatible with death from shock due to water suddenly entering the baby's nostrils. He considered that such a shock might have resulted if the baby fell from its mother's arms and rolled down the bank into the water. Counsel submitted that, if this evidence had been tendered at the trial, it might well have inspired the jury with a reasonable doubt of Mrs. Harding's guilt. The Court of Criminal Appeal accepted this contention. The judges could not say that, if this evidence had been tendered at the trial, the summing-up might not have been different and the jury might not have come to a different conclusion. The conviction was therefore quashed.

Two points may be worth a final word. First, the Lord Chief Justice, in delivering the judgment of the appellate court, was careful to observe that the circumstances were quite exceptional and unprecedented and were never likely to be repeated. In other words, the Court of Criminal Appeal is guarding itself against the risk of being asked to reopen every case on appeal by the tendering of fresh evidence. The proceedings on appeal are not a rehearing. The appellate tribunal has been conspicuously reluctant to hear fresh witnesses—particularly perhaps medical witnesses where the defence is insanity. Secondly, it seems strange that the evidence offered on behalf of Mrs. Harding on appeal was not offered at the original trial. The explanation is that she was defended under the Poor Prisoners' Defence

Act. She had therefore, apparently, inadequate facilities for obtaining the help of medical evidence to rebut the medical evidence adduced by the Crown. There have, however, surely been cases where the accused, having been granted legal aid at the public expense, has had the advantage of being able to call expert witnesses in support of the defence. It would shock the public conscience if it were true that the defence of poor persons is not properly equipped.

### Claim for Damages for Food Poisoning

In *Mence v. Thierry* a visitor unsuccessfully sued a hotel for damages for alleged negligence and breach of warranty in respect of food served at luncheon. He said he stayed at the hotel on a golfing holiday last September and was given a croquet of salmon and turbot served in a scallop shell with cheese sauce; he complained that it was unfit for human consumption and that he suffered from gastro-enteritis as a result of eating it. He said he was violently sick in the afternoon and two days later, being still ill, he returned home on medical advice; he had been unable to attend regularly to his business till January. Doctors called by the plaintiff could give the court no other explanation of his illness except the eating of the fish. On the other hand, it was contended that the browning of the sauce at grilling heat would kill any germs. There was also evidence that 85 portions of this dish were served and that the plaintiff made the only complaint. Mr. Justice Porter said he accepted the fact that the plaintiff expressed dissatisfaction with the taste of the fish at the time, but it was not established that the eating of the fish caused the illness. The poison was toxic and not bacterial; though the salmon and turbot were mixed and served to a number of people, nobody else was affected; the course of the plaintiff's illness did not seem to be such as would be attributable to toxic poisoning. It would, said the judge, be too speculative to find in favour of the plaintiff; the case had not been made out, and there must be judgment with costs for the defendant hotel.

## AUSTRALASIA

(FROM OUR OWN CORRESPONDENT)

### INTRAVENOUS OLIVE OIL EMULSION THERAPY

CONSIDERABLE interest has been taken recently in Australia in the claims made for the intravenous injection of olive oil in the treatment of septicæmia, pneumonia, and certain toxic conditions. A report has appeared<sup>1</sup> of a case diagnosed as septicæmia, the infection following removal of tonsils and adenoids. The only treatment given was a three-hourly intravenous injection of olive oil, followed by a daily maintenance dose. Within seven hours there was a remarkable improvement in the temperature, which dropped 4° F. and returned to normal next day, after which recovery was rapid and uneventful. Good results are reported in other cases. This method of treatment has resulted from the work of V. G. Walsh and A. C. Fraser.<sup>2</sup> The experimental basis is that when lethal doses of various toxins are mixed with olive oil and injected into animals, death does not take place, and that similar absorption of the toxin takes place when the

<sup>1</sup> Med. Jour. Australia, 1935, I., 661.

<sup>2</sup> Jour. of Physiol., 1933, lxxviii., 467; and Brit. Med. Jour., 1934, I., 424.

olive oil is introduced into the blood of patients with toxin circulating in their blood. Walsh invented an ingenious machine for emulsifying the oil so that the droplets should be sufficiently small to pass the capillaries without fear of embolism.

In criticisms of the method it has been objected that the experiment on which it is based is unsound, and that the recoveries claimed for the oil are capable of other explanations and may be due, for example, to the crisis in pneumonia, the bursting of abscesses internally, or to therapeutic measures such as curettage employed at the same time as the injections. Cerebral embolism, hæmaturia, and death are said to have occasionally followed the introduction of oil and the analogy of another oil—sodium morrhuate—as an occasional cause of embolism has been quoted. It is known that solutions of various chemical substances in olive oil—e.g., local anæsthetics—are absorbed extremely slowly when injected into the subcutaneous tissues of the body, and this is the basis of the use of A.B.A. and similar solutions. We know little, if anything, of the absorption of oily solutions introduced intravenously, and the hypothesis that the oil introduced into the blood stream will attract and absorb circulating toxin is entirely unsupported by any evidence. It has even been suggested that any therapeutic effects of olive oil might be just as well expected if it were given by mouth instead of intravenously. Further, the claim that it is of value in pneumonia and septicæmia must surely imply that its action is not only one of absorption of toxin but also directly bactericidal. Many who have seen the oil used therapeutically are far from convinced. It is thought that sufficient patients have been treated for a proper record of a consecutive series to have been published instead of reports of occasional and seemingly miraculous cases. The crucial experiment on which the treatment should rest is surely the giving of a lethal dose of toxin, followed by an intravenous injection of the emulsion. It is more or less generally felt that the method should be much further investigated experimentally before being used therapeutically in man.

#### MOTOR ACCIDENTS

The problem of the prevention of motor accidents is disturbing the Governments of both New South Wales and Victoria. In the former, figures for January and February, 1936, show an increase of 43.9 and 51.9 per cent. on the corresponding months of last year and 1934 respectively, allowance having been made for the number of cars. Taxi-cabs have been involved in more accidents than their numbers warrant. As in England, there is some difference of opinion about the responsibility of high speeds for accidents and there is considerable opposition to the introduction of low speed limits. The latest investigations have been directed to the responsibility of new cars for accidents. The percentage figures of these were 15.4 of the total registrations and were involved in 21.9 of the accidents during last December and January; new lorries and vans (19.0) were concerned in 29.2 and new motor-cycles (9.4) in 22.6. Many suggestions are being made for drastic amendment of the present traffic laws, including provision for compulsory third-party insurance.

#### MATERNAL AND INFANT WELFARE

Dr. R. Marshall Allan, professor of obstetrics in the University of Melbourne, in the course of the

annual Ann Mackenzie oration, criticised the Federal Government's decisions for the expenditure of money subscribed for infant and maternal welfare. It was more a spectacular gesture, he said, than one likely to lead to any permanent improvement. The public has been confused by statements concerning the maternal mortality-rate in different countries and he thought that inaccurate comparisons of Australia with other countries are being made, which tend to make the public believe that Australia is much worse off than is the case. The present system of compiling statistics in different countries affords an opportunity to the propagandist to alarm the public. Much good has come from antenatal clinics, which should be placed under medical supervision, and baby health centres are of considerable value.

## PARIS

(FROM OUR OWN CORRESPONDENT)

#### PRECAUTIONS AGAINST INFECTION AT AUTOPSIES

A SERIES of post-mortem room infections has led Dr. L. Mourier, administrative head of the Assistance Publique in Paris, to issue a rather strongly worded circular to the directors of the public hospitals here. He pointed out that some laxity has crept into the conduct of post-mortem examinations, which according to the regulations should be strictly supervised by the heads of hospital services. It seems that hospital externs have of late been in the habit of conducting them not always under the eyes of their teachers. This practice has its *raison d'être*; what is more simple and convenient for a busy hospital physician or surgeon than to let externs carry out by themselves the more or less mechanical preliminary stages of a necropsy, and only when all the organs have been isolated to visit the post-mortem room and inspect them with his interns and others? Dr. Mourier's injunction to the heads of hospital services to spend more of their valuable time in the supervision of autopsies has not been taken in good part, and it has even been suggested that his circular was inspired by a craving to play to the gallery occupied by representatives of ratepayers disinclined to pay for the cost of accidents. It is certainly true that in his circular Dr. Mourier washed his hands of all pecuniary responsibility for such infections, insisting that the infected extern or his hospital chief must in person pay the piper. The storm of protest against the circular has successfully blown it back into Dr. Mourier's office where it has been interred. Another edict, drafted in a more chastened spirit, has now replaced the first. Henceforth post-mortem examinations are still to be conducted by externs and interns, but there is to be a certain tightening up of the formalities in the hope that carelessness conducive to post-mortem room infections will be checked.

#### EXPLOITATION OF THE PUBLIC HOSPITALS BY THE RICH

With every increase in the comfort provided by the French public hospitals there is a corresponding increase in the number of well-to-do patients anxious to enjoy it. This may seem natural enough to the public in general and particularly to those patients who, like your John Gilpin, have a frugal mind; but it sticks in the gullets of the private practitioners who

lose these patients and of the hospital doctors who inherit them and have to treat them for nothing. An echo of these sentiments is to be found in an appeal issued by Dr. Georges Audain to all whom it may concern to add to the dossier he is building up about well-to-do patients who have crept into beds needed by the poor. This appeal is addressed not only to general practitioners and hospital doctors, but also to hospital interns and externs. Indeed, it is for these prospective doctors that Dr. Audain's activities should, in his opinion, prove most beneficial, for they may well find on starting medical practice in a few years' time that this tendency has grown into a habit so widespread that they may find no private patients awaiting them. Specially selected for the black list are the well-to-do provincials who come to Paris to fill the one-bed wards of the general hospitals. It seems a pity that anyone and everyone should be roped in to spy on the proceedings, however nefarious, of supposedly well-to-do patients enjoying the hospitality of beds in public hospitals. Wealth and poverty are such relative conceptions that a callow medical student can hardly be expected to pose as a judge and denunciator in so delicate a matter; and it is to be hoped that the hospital authorities themselves will deal with it and not leave it to any budding Sherlock Holmes.

#### BACK TO THE LARGE-WARD HOSPITAL

Dr. Raphaël Massart, who is on the editorial staff of *Concours Médical*, has contributed an essay to that journal on the virtues of the large 30-bed ward and the vices of the hospital partitioned off into a lot of small wards. He admits that the evolution from the large to the small ward has for some time been a tendency common to hospital architects as a class. In the provinces as well as in Paris the large wards are falling into disrepute to the disadvantage, according to Dr. Massart, of all concerned, the patient included. In the modern small-ward hospital, doctors, nurses, and medical students play a continuous game of hide-and-seek. All cannot be in the same small ward together, and there is an incessant scuttle from one ward to another, with opening and shutting of doors, shouting, and other evidence of distraction. How can thoracentesis or lumbar puncture be demonstrated to a class when all concerned are packed like herrings in a barrel? In the small ward, supervision of the patient is hampered and he is tempted to indulge in forbidden conspiracies with those who visit him. Left to himself, he becomes bored and does not enjoy those minor services which patients in a large ward render each other with more promptness and camaraderie than overworked nurses. It is so much easier to ask your convalescent neighbour in the bed next you to pass you the urinal than to lie helpless and fuming in a single-bed ward ringing and waiting and waiting and waiting. Yet another fault inherent in the one-bed ward is the temptation it offers to the well-to-do patient who does not deserve it. What has hitherto kept him out of the public hospitals has been his dread of the many-bed ward—whose attractions seem somehow or other to have escaped his notice.

**GRANTS TO LEEDS HOSPITALS.**—Grants totalling £57,660 have been made to Leeds hospitals by the Leeds and district workpeople's hospital fund. The grants include an award of £40,000 to the General Infirmary. The income of the fund increased last year by over £8000, owing to an increase in the workshops of the city.

## BRITISH CONGRESS OF OBSTETRICS AND GYNÆCOLOGY

THE tenth meeting of this congress held at Belfast on April 1st to 3rd, Prof. R. J. JOHNSTONE presiding, was mainly devoted to discussions on the

### RESULTS OF CONSERVATIVE TREATMENT in its various aspects. At the first morning session Prof. JAMES HENDRY spoke on Conservative Treatment of The Ovaries

He said that ovariectomy was the pioneer abdominal operation, representing the triumph of surgical technique over physiological principles. The practice of ovariectomy depended on an ill-founded belief in the ovary as the cause of pelvic pain; whereas conservative treatment was based on the recognition of the ovary as an endocrine gland with many functions: fertility, menstruation, and balanced endocrine function, the loss of which constituted the pathological menopause. Experimental work on ovarian grafts had demonstrated the superiority of ovaries in situ over all grafts, which were liable to degenerative changes and in any case functioned only for a limited period. All who had used grafts agreed that a graft cannot compare with a normal ovary. Conservation of fertility required an intact uterus and persisting ovulation, with access to the uterine cavity, but a relatively small amount of ovarian tissue was necessary. Prof. Hendry referred to the case in which Sir Halliday Croom had removed both ovaries and implanted an ovary from another woman; four years later the patient had a normal confinement. Conservation of menstruation required a menstruating surface and an adequate amount of ovarian tissue. Menstruation could be re-established by ovarian grafting. The duration of efficiency of ovarian grafts was from two to three years. Conservation of endocrine balance was difficult to assess; "flushings" were the most reliable sign. The disturbance caused by the spontaneous menopause varied in different individuals. In the absence of the uterus an ovarian transplant had no value and in the conservation of endocrine balance only a limited value. The subjective symptoms of continued ovarian function were too uncertain to be of much value; the three important physical signs were (1) high glycogen content in vaginal mucous membrane, (2) homogeneous grade A flora in vagina, and (3) continued acidity of vaginal secretion (pH 4.0 to 4.6). The dangers of conservative treatment of the ovaries were: degenerative changes in retained ovarian tissue, malignant changes, and changes in ovarian grafts. Prof. Hendry suggested as possible conclusions: (1) Ovarian tissue should be saved in situ wherever possible. In one of his cases a large ovarian dermoid was removed on one side and a smaller dermoid resected on the other, leaving a little ovarian tissue; pregnancy followed five months later. (2) Conservative treatment of pelvic inflammatory lesions was advantageous; late operation, if it became necessary, allowed better scope for preserving ovarian tissue in its natural relationships. (3) Where a functional part of the uterus was saved and healthy ovarian tissue could not be retained in its natural relationships, ovarian grafts might be used to conserve either fertility or menstrual function. (4) In the absence of a uterus the conservation of ovarian tissue was not essential; in these cases the administration of standardised ovarian hormones was

of more permanent use than retained or grafted ovarian tissue.

### The Fallopian Tubes

Dr. BETHEL SOLOMONS said that for acute salpingitis palliative treatment was the method of choice. The arguments had been effectively discussed at a previous congress, and therefore need not be further considered. In the investigation of chronic salpingitis it must be remembered that lipiodol was not altogether safe. Five deaths and 13 infections had been reported in 2000 cases, and the danger was increased if the injection was followed by immediate operation. The inflation test might give a false impression of blockage, if fibroids and retroversion were present, unless an X ray examination was made. Operative treatment designed to produce fertility yielded success only in 10 per cent. of cases and this should be explained to the patient and to her husband, who should, moreover, be tested for fertility before the wife is treated surgically. From the answers to the questionnaire sent out it had emerged that Dr. Rubin operates more and more on *all* parts of tubes with good results. Operation was much more likely to result in patency than in pregnancy; but pregnancies had followed all types of operation, including the resection of the uterine end and implantation.

### The Uterus

Prof. A. LEYLAND ROBINSON described the functions of the uterus under the headings (1) reproductive, (2) menstrual, (3) sexual, (4) metabolic, (5) mechanical, (6) sociological, and discussed the principles underlying the application of conservative measures. Among the simple expectant methods of conserving the pregnant and the non-pregnant uterus, the practice of antenatal work, he said, took pride of place. Antenatal period began during the *intra-uterine* life of the individual. Unfortunately the success of this antenatal work had given rise to a new type of obstetrician who emphasised the necessity for the practice of conservative methods during pregnancy, but regarded labour more as a surgical procedure than a natural process, and Cæsarean section as the only means of dealing with any complication arising during the act of birth. The increasing popularity of the lower segment technique had, however, set up a current in favour of conservatism by demonstrating that it was safe and indeed advantageous to give the natural powers fair trial before resorting to surgical methods of delivery. Postnatal care was still far behind antenatal work; the development of many morbid conditions and much dysfunction could be avoided by the application of the appropriate method at the proper time. In gynæcology expectant methods were employed with fair success for acute uterine infection, but their application to subacute and chronic conditions was much less satisfactory. In severe cases of inflammatory disease the best results could still only be obtained by the employment of radical methods. In the treatment of certain types of innocent uterine tumours, expectant methods might be employed with safety and success, but in malignant neoplasms conservative treatment had but a small part to play. Perhaps the practice of better postnatal care, such as the careful immediate repair of cervical injuries inflicted during labour, would reduce the present incidence of carcinoma of the cervix. Those clinics where all torn cervixes were repaired reported a lower incidence of carcinoma.

Conservatism in surgery had been encouraged by the success of simple surgical measures for innocent

tumours, for example, myomectomy for fibroids. The most recent figures, published by Fahndrich, suggested that the risk entailed by the conservation of the cervix in subtotal hysterectomy for malignant disease of the body of the uterus had been exaggerated. The additional immediate risk of a total hysterectomy over a subtotal one must be taken into consideration when the decision between the two operations was taken. The conservation of uterine function had been encouraged still further by the modern conception of the significance of uterine displacements. It was now realised that active interference was rarely required for simple types of backward displacement. Surgical methods had also been displaced by the introduction of other forms of treatment such as radium, X rays, and hormone therapy; since irradiation was not entirely a conservative method of treatment it was to be hoped that in the future hormone therapy might replace X rays and render surgery obsolete. Much of our best treatment was still necessarily empirical. Dr. Robinson then indicated briefly the problems awaiting solution in connexion with the four topics chosen for special investigation which were to be the subject of communications by other members of the congress: myomectomy, radium for intra-uterine bleeding, the treatment of endocervicitis, and the scope of hormone therapy for functional hæmorrhage.

Mr. A. A. GEMMELL gave a report on

### Myomectomy

based on a study of the literature, the replies to a questionnaire sent all over the world, and the case records of a group of Liverpool gynæcologists. Abdominal myomectomy only was considered, as vaginal myomectomy so often meant nothing more than the removal of a fibroid polyp. The advantages were that the operation involved no physiological changes, but this was no compensation if it entailed greater risks than did hysterectomy. The decision between the operations could not be taken until the abdomen was opened. The contra-indications were malignant change or degeneration; Victor Bonney and Leith Murray held that red degeneration and hyaline change were not contra-indications. The incidence of sarcoma occurring in a fibroid varied in different reports from 0.24 to 2.3 per cent. The lowest percentage given was 0.09. The main principles to be observed in carrying out the operation were asepsis, hæmostasis, peritonisation, and the closure of cavities. Mr. Gemmell himself did not practise lipiodol radiology. The mortality of myomectomy was about 2 per cent., the chief cause of death being sepsis. Normal menstruation continued in over 80 per cent. of the cases. Bright Banister had reported six myomectomies for sterility followed by pregnancy.

The objections which had been brought up against the operation were (1) an alleged high morbidity, not supported by the literature; (2) the danger of rupture of scar in subsequent pregnancies—no such accident had occurred in the Liverpool series though 11 cases were recorded in the literature; and (3) the possibility of recurrence. The average recurrence rate was about 4 per cent., and it must be remembered that fibroids might recur in a cervical stump. In making the decision the age of the patient must be considered, and also the thoroughness with which seedlings would be removed. Most cases recurred within five years or not at all. Of operations undertaken during pregnancy 81 per cent. were followed by living children. The danger of abortion was least in operations done at about the fifth month. During labour the mortality of the operation was

15.4 per cent., so that it was safer at this period to do hysterectomy.

### Discussion

Dr. GEORGE GRAY WARD (New York) said he was in accord with what previous speakers had said except for slight differences in detail. Conservation of ovarian tissue was now his rule. He agreed that the life of grafts was limited, but thought it worth while to insert them even if their activity lasted only a few years. He described a case in which he had removed two ovarian cysts the size of grape-fruits in a young recently married woman; he had shelled out the cysts and made two tiny rudimentary ovaries. The patient subsequently bore a healthy child. As to the Fallopian tubes, Frank Simpson, of Pittsburgh, produced an epoch-making contribution to gynæcology when in 1909 he advocated delayed operation in acute tubal inflammation. The operative mortality in acute stages was 20 per cent., and in the delayed operation only 1 per cent. An operation delayed until symptoms had completely subsided and temperature had been normal for three weeks was the accepted practice in America to-day. General surgeons still tended to say: "Hot appendix, hot tube; out it comes." Dr. Gray Ward described a case operated on for sterility and adhesions four years after an acute salpingitis, a hydrosalpinx being removed on one side and salpingostomy being performed on the other. Pregnancy followed five months later. He also described and showed illustrations of an operation for temporary sterilisation, and reported a case of pregnancy following a second operation to reopen tubes.

Dr. O'DONEL BROWNE (Dublin) said that the results of his operations for restoring the patency of the Fallopian tubes had hitherto been disappointing, and that patients should be warned not to expect too much. He described a case where he had done an end-to-end anastomosis of one tube and found the condition of the other hopeless. The patient subsequently became pregnant and was delivered by Cæsarean section, when it was seen that the anastomosis had failed and the "hopeless" tube had recovered. He described some interesting operations on rabbits' tubes, of which the results were not yet ready for publication.

Mr. EARDLEY HOLLAND, speaking on the conservation of ovarian tissue, said that nearly everyone was careless of the need to leave some ovarian tissue behind. Dermoids and epöphoric cysts should always be shelled out, and this was worth while even if only a few ovarian follicles were left. Mr. Holland had operated on two patients with bilateral dermoids, both of whom had since had children. In bilateral endometrial cysts it was always possible to leave a little ovarian tissue, and in four such cases the women had since had children. He had never succeeded in leaving ovarian tissue in pseudo-mucinous cysts, and doubted whether it would be right to try. Otherwise it was worth while running the risk of a further operation. Speaking of tubal conservation, he said that the fimbriated end was not necessary for the occurrence of pregnancy; if, therefore, the middle of the tube was stenosed, it was only necessary to excise this portion or simply to snip it apart. Anastomosis was unnecessary.

Prof. E. FARQUHAR MURRAY, speaking on the conservative treatment of ovaries, reminded the congress that even in very young women ovarian cysts might prove to be malignant. As to tubes he recommended the injection of lipiodol before operating on a tubo-ovarian mass, otherwise it might be impossible to

estimate the degree of patency. The lipiodol might also prove to be curative. He thought that the high mortality of myomectomy combined with Cæsarean section was accounted for by the fact that many of the cases for which these procedures were performed together were cases of obstructed labour.

Prof. J. YOUNG doubted whether it was often possible to be conservative in cases of endometrioma. He thought the risk of panhysterectomy was so much greater than that of subtotal hysterectomy that the former procedure should not be advocated in a teaching school. He agreed that cervical infections were among the commonest gynæcological conditions and applauded Dr. Herd's reference to the cervix as the "pelvic tonsil." Faulty drainage made cervical lesions very unlikely to heal spontaneously, and one of the most essential points in their treatment was full dilatation of the cervix. He agreed with Dr. Gray Ward that cauterisation should be superficial and not deep, and said that it was important to puncture all follicles in addition. Many cervical lesions caused referred pain in the iliac fossa. This could be stirred up by touching the cervix and often disappeared when the cervical tension was relieved. Other reflex symptoms might be bladder irritation and pain in the renal area due to irritation of the pelvic sympathetic fibres.

Prof. D. DOUGAL said that he was brought up in a radical atmosphere where if the uterus was removed, the ovaries were removed too. He had since become a left wing or centre conservative, and did not even agree that the ovaries should be removed at the menopause, for this made subsequent adjustment more difficult. He agreed with Dr. Young that in endometrioma there was only occasionally scope for conservative measures, and thought it possible that retained ovarian influence might keep the growth active. With regard to myomectomy, he thought it was no satisfaction to a patient to have an operation and not be cured of her symptoms. He did not consider panhysterectomy more dangerous than subtotal, and the former had the advantage of an opening into the vagina for drainage.

Prof. MILES PHILLIPS said he was an ardent supporter of panhysterectomy but did the subtotal operation in selected cases. He stressed the value of an historical survey as a means of preventing dangerous swings of the pendulum. He had no experience of ovarian grafting, but had had very good results from leaving scraps of ovary in situ. He had regretted having left it in cases of true endometrioma. He believed that if the uterus had to be removed, the patient was better without the ovaries and quoted his case of a girl of 18 where the uterus and ovaries were removed for sarcoma botryoides; ten years later the patient was living happily married with no sign of lack of ovarian function. The worst cases of lacerated cervix were best treated by the Sturmdorff amputation, which did not lead to delay in labour. Carcinoma of cervix was the only type of carcinoma which was on the decrease, and this was due to more frequent amputations.

Prof. R. M. WINDEYER (Sydney) said he was interested to hear that red degeneration of fibroids was rare in England. It was very rare also in his experience. He was glad that the meeting favoured conservation. He had removed a fibroid from the lower part of the uterus in a patient five months' pregnant, and though the membranes were practically exposed he had oversewn the area, and the patient subsequently had a normal delivery.

At the first afternoon session, Prof. FLETCHER SHAW presiding, Dr. S. B. HERD read a communication on the

### Conservative Treatment of Endocervicitis

He said that for the purpose of this paper endocervicitis had been taken to include all pathological conditions of the cervix, with the exception of acute gonorrhoeal, tuberculous, and syphilitic infections, and all neoplastic conditions. Conservative treatment could be defined as the employment of those measures likely to produce best results with the least possible interference with the normal genital functions. Dr. Herd then discussed the advantages and disadvantages of conservative measures, taking cognisance of the following factors: relief of symptoms, effect on possible pregnancy, prevention of malignancy, and subsequent development of stenosis.

The analysis of successful therapeutic measures was difficult because the condition was often complicated by something else—for example, prolapse. Of the various methods of treatment antiseptics (mercurochrome douches, and so forth) had their place. The results of curetting the cervix were unsatisfactory. Ultra-violet light was useful if combined with diathermy. Caustics might do good, but might lead to stenosis. Thermo- or electro-cauterisation with preliminary dilatation of the cervix to ensure good drainage was favoured by some. Diathermy coagulation in the opinion of many authorities had replaced almost all other methods unless the lacerations were very deep. Trachelorrhaphy was best done soon after parturition. The questionnaire issued on the subject had given rise to very varied replies. For deep lacerations most of those who answered preferred amputation, usually Sturmdorff's. In Liverpool the majority of cases of torn infected cervix were treated by Sturmdorff's amputation. Coagulation diathermy, cauterisation, and Sturmdorff's operation all increased fertility. There was slightly more danger of abortion after amputation, also of delays in the first stage of labour. In a series of 7000 cases of amputation of cervix no cancer had developed. Hæmorrhage and infection were more likely to follow deep cauterisation than any

other treatment. In Dr. Herd's view it was necessary to use different methods for different cases.

Dr. GRAY WARD agreed on the importance of varying the type of treatment to suit the case, and laid stress on the difference between cauterisation, which was a burn, and might be followed by stenosis and electrocoagulation which caused no tissue charring. In his postnatal clinic 50 per cent. of cases were found to have cervical erosions. If lacerations and erosions were still present after eight weeks they were treated by diathermy as ambulatory cases. There were only two failures in 120 cases and no stenosis followed.

In the absence of Dr. DE SA through illness, his communication on Conservative Therapeutics in Gynæcology was not delivered, and instead Dr. JAMES HEYMAN (Stockholm) discussed a subject not on the official programmes, namely

### Grouping of Cases of Cancer of Cervix

He said that uniformity in estimating results was only possible if these were based on an absolute as opposed to a relative cure rate, but that many clinics could not state their absolute cure rate because they dealt only with selected cases. The relative cure rate was much less accurate, but when it was employed, similar groups of cases should be compared. He reminded the members of the now classical definitions of the four stages of carcinoma of cervix, but deplored the fact that different clinicians were not agreed on the stage to which a given case should be assigned, particularly as between stages 2 and 3. He then showed about 20 beautifully prepared schematic drawings of cases in all four stages and invited the members of the congress to indicate on sheets of paper prepared for the purpose the stages to which they would assign the different cases. He felt it necessary to add that no prize would be awarded for the best achievement. Later, when Dr. Heyman thanked his "collaborators" for their assistance in relegating the cases to their appropriate groups, it became clear that he had by no means overstated difference of opinion that might well vitiate statistics. (To be continued)

## PANEL AND CONTRACT PRACTICE

### Sickness and Unemployment Benefits

THE *National Insurance Gazette* is concerned over the different levels of benefit for the same trouble. The *Gazette* points out that when recommending the reduction of unemployment insurance contributions by 1d. per week for each party the Statutory Committee indicated that social insurance should be looked at as a whole. This recalls the position which existed in 1911 when unemployment insurance constituted Part II. of the first National Insurance Act. The provision for unemployment is already on a higher scale than that for sickness; in many cases it approaches the level of wages and may even surpass wages. There are dangers in having the benefit rates for unemployment and for sickness at widely differing levels, as there are also dangers in making the compensation for loss of wages in any particular case equal to, or greater than, wages. In the committee's opinion any increase of unemployment benefit rates in general should now be made only after full consideration by Parliament, as an act of deliberate social policy, and not simply because a decline in unemployment has produced a surplus in the Unemployment Fund. In a pamphlet entitled

"Merseyside; the Relief of the Poor" Prof. Caradog Jones suggests that the lower rate of benefit paid to the sick man, as compared with the unemployed man, results in the unemployed man when sick being transferred from the unemployment insurance fund to the rates—the sick man calls on public assistance to make up his sickness or disablement benefit to something comparable with unemployment benefit.

The sick man needs no less money than when he is well; his recovery is assisted by adequate nourishment, and the knowledge that his dependants are not suffering. Whether the money from insurance funds should be supplemented by the ratepayer or by the State is not for us to decide, but the wide divergence in the benefit rates for unemployment and for sickness is illogical. Admittedly there is a closer hold, through the employment exchanges, on the recipient of unemployment benefit than on his ailing brother, in the mind of whose insurance doctor there may be conflict whether or not to certify him as incapable of work. When work is plentiful there is little incentive for the insured person to prolong his disability, particularly if sickness pay falls far short of what can be earned at work, but there is also the danger of a premature return. The *Gazette*

would like a Royal Commission to consider the whole question and make recommendations for coördination, possibly also with a view to laying down a minimum weekly sum for workmen's compensation benefit. There are tiresome anomalies—for instance the black-coated worker often has his sickness benefit made up to his normal salary, at any rate for a time, by his employer, but the artisan is seldom so lucky; increase in the statutory rate of sickness benefit would benefit the employers in the first class but not in the second. Our system of social insurance has grown up piecemeal and there are many who think that such an examination of it is overdue.

#### Notification of Tuberculosis in London

In the county of London for the four years 1931 to 1934 some 12 per cent. of pulmonary and 40 per cent. of non-pulmonary cases of tuberculosis were not notified before death. Many others were only notified at a very late stage of the disease or even when death was impending. In view of the fact that all forms of tuberculosis were made compulsorily notifiable as long ago as 1912, it is rather disturbing to find that so many cases still evade the supervision of the local public health department. The London

medical benefit subcommittee has been considering how an earlier notification of cases might be secured. The omission may in part be explained by the fact that under Article 5 of the Public Health (Tuberculosis) Regulations, 1930, a medical practitioner is not required to notify a case if he has reasonable grounds for believing that the case has in fact already been notified in the district. The doctor may be wilfully misled by the patient who does not wish to be visited and advised from the dispensary. Tuberculous patients may fear to be told they are suffering from the disease and refrain on this account from placing themselves under the care of a doctor until the disease is far advanced. The committee felt helpless to persuade patients to apply earlier to their doctors. But as the outcome of its inquiry it has issued a letter to each doctor on the list containing a reminder that under Clause 9 (13) of the terms of service an insurance practitioner is required to prepare and send (on Form G.P. 17) to the tuberculosis officer a report on each patient whom he finds to be suffering from tuberculosis as soon as he makes the discovery. Medical officers of health of London boroughs are being informed of the action taken by the committee in the hope that non-insurance practitioners may be led to coöperate.

## PUBLIC HEALTH

### The New Clean Milk Policy

THE new designations for milk in commerce did not come into force on the first of this month as expected. The operation of the new order has been postponed until June 1st and the Minister of Health has not yet announced his decision about the designations themselves. It seems clear that sufficient time has not elapsed for those concerned to appreciate all the points made by Prof. G. S. Wilson and his colleagues in a critical study of the bacteriological grading of milk which appeared in January and was then summarised in our columns (Jan. 25th, p. 217). The new grades of milk, as set out in the draft order, are to be graded partly on the number of bacteria they contain—a maximum of 30,000 and 100,000 per c.cm. for the two grades of pasteurised milk; 200,000 for the two grades of fresh milk. But after the end of the present year the bacteriological test for fresh milk will be replaced by the methylene-blue reduction test, and about the working of this test there has evidently been some misconception. Prof. Wilson's committee found the methylene-blue test fulfilled most of the requirements demanded of a test for the routine grading of raw milk, but they expressed doubt whether the test was suitable for the examination of freshly pasteurised milk. Mrs. Foot, a "Certified" milk producer of Berkhamsted, added a teaspoonful of cow manure to some one-pint samples of her high-grade milk, sent the mixture to a bacteriologist, and was assured by him that the milk easily passed the standard laid down for the new tuberculin-tested grade. She was, it seems, unaware that in the new order the Minister has definitely lowered the standard of cleanliness. There is no longer any grade of milk corresponding to the present top grade known as Certified which is what Mrs. Foot herself produces; but apart from this the experiment itself was not very wisely conceived. Although manure contains a fairly large number of organisms, many of them are dead and it is well known that gross particulate matter can be added to milk without greatly affecting the plate count. The addition of manure to Certified milk produces only a small absolute increase in the

plate count and generally lowers the reduction time by about one hour—the reduction time still being longer than that laid down for the new tuberculin-tested grade. This is abusing the test because it does not condemn a milk of a higher standard of cleanliness than the one for which the test was proposed. If the Ministry had wished to retain the present Certified standard and had laid down a reduction time of (say) 7½ and 8½ hours, in summer and winter respectively, then Mrs. Foot's manure-contaminated milk would have been condemned. It seems worth while to make it clear that Mrs. Foot's experiment was not designed to prove what it was intended to prove. The methylene-blue reduction test, like many other tests in applied chemistry, is only valid within certain limits within which it is intended to be used, and the standards laid down refer only to milk that has been kept at atmospheric temperature for the prescribed time. Crude extraneous matter can be detected much more easily by simple sediment tests than by any bacterial test, and the bacterial tests that are in use are not designed to detect matter of this type. Even the coliform test is not of any real value for the purpose; though it is true that the addition of manure to milk will probably be reflected in the occurrence of coliform bacilli, the reverse does not hold true. Should such bacilli be found in milk it is not justifiable to conclude that the milk is contaminated with excremental material. There are many other sources of coliform bacilli on a farm. Moreover it is quite possible for manure-contaminated milk to pass both the plate-count and the coliform tests at present laid down for Certified milk.

The real conclusion is that the methylene-blue reduction test seems satisfactory for grading milk on a basis of bacterial cleanliness, provided the reduction time is adjusted to the particular grade of milk which the test is designed to control. The plate-count and the methylene-blue tests give closely related results, and there seems no reason to doubt that the grading of milk will be any less satisfactory when performed by the reduction test than when performed by the plate count. There are indeed several grounds for believing the contrary.

## CORRESPONDENCE

VITAMIN B<sub>1</sub> BY INJECTION IN THE  
TREATMENT OF NERVOUS DISEASES

To the Editor of THE LANCET

SIR,—A propos of your annotation on Dr. Ritchie Russell's work on the parenteral administration of vitamin B<sub>1</sub> (March 28th, p. 727) brief details of a case of polyneuritis which I have recently been treating with a similar preparation may be of interest. In this case the product used was prepared by Glaxo Laboratories over two years ago and contains 100 international units of vitamin B<sub>1</sub> per 5 c.cm.

The patient, a woman of 24, developed a rapidly spreading polyneuritis of unknown origin, with widespread sensory loss and weakness especially of the left arm and leg. On March 13th last she could not lift her left arm or leg off the bed nor turn herself over; even to raise her head was an effort and there was marked wasting of some of the arm muscles, particularly the intrinsic muscles of the hand. Injections were given on March 13th, 19th, 23rd, and 27th. On March 15th—i.e., two days after the first injection—she could keep her hand raised above her head, on March 19th she turned herself over in bed, and on March 25th she stood up out of bed (without permission). She can now walk tolerably well, has full, though weak, movements of her hands, and the wasting of the muscles is already much less. The sensory loss has been much slower in returning, though the last four days have shown considerable improvement. The wasting of the muscles seems to show definitely that this is not a case of neurosis, as one might otherwise suspect.

For the past five years I have been using a solution of vitamins A and D for parenteral administration, also made by Glaxo Laboratories, and have written a paper on the highly interesting results which will, I hope, shortly be published. It is however worth recording that when summarising my preliminary results in my M.D. thesis three years ago I made the same observation which Dr. Russell has made in connexion with vitamin B<sub>1</sub>—namely, that the parenteral injection seems to give a quick response apart from any demonstrable vitamin deficiency. But while he suggests that this might be used to diagnose vitamin deficiency I suggested that it might be used to investigate the action of vitamins by studying the effects of a rapidly induced excess rather than a slowly induced deficiency. Both suggestions are, I believe, of value.

As not long ago I wrote a letter in the *British Medical Journal* championing the cause of the foreign chemical firms, I hope I may here say, without offence or chauvinism, that when our own firms are able and willing, even anxious, to provide these experimental products, it seems a pity that Dr. Russell should have gone to a continental firm for his supplies, even though it be to one of the supreme excellence of Hoffmann-La Roche. Compliance with British ethical standards and government regulations puts a heavy handicap on our pharmaceutical manufacturers which is not always realised, and if they lack deliberate support from pioneers in treatment they are more heavily handicapped still.

I am, Sir, yours faithfully,

Winsford, Cheshire, April 3rd.

W. N. LEAK.

## SARDINES UNFIT FOR HUMAN FOOD

To the Editor of THE LANCET

SIR,—Under the above heading, on p. 800 of your last issue, you say "A recent prosecution at the Mansion House disclosed some discreditable dealings in sardines unfit for human food. For some reason, which puzzled the presiding alderman, a consignment found unsatisfactory when examined at the London Docks last July was not condemned and destroyed forthwith at the time but was allowed to be sent back to the Portuguese packers." These words might be taken to suggest that the officers of the Port of London Sanitary Authority were at least a party to the "discreditable dealings." Officials of the public services are not expected to defend themselves in the press, and I have therefore allowed the observations of the magistrate as reported in the *Times* of March 27th to pass without comment, but I feel that I am justified in taking exception to your report of the case.

For some time past the Port of London Sanitary Authority has, quietly and without appeal to a magistrate's court, been dealing with the problem of the contamination of sardines with lead and great improvement has been effected. It was neither necessary nor desirable to ruin the sardine industry and the English importers by suddenly insisting on a change in old-established methods of preparation and packing. The object was simply to reduce to a minimum the amount of lead unwittingly ingested by the inhabitants of this country. Consignments found on chemical analysis to contain more than a few parts per million of lead have been stopped in the port and, for the reasons stated, have been returned to the packer on receipt of a guarantee that they would not be returned to any port in this country.

The consignment in question was, on its arrival in the Port of London in July, observed to contain a number of tins which had been blown and resoldered. Samples on analysis were found to contain 36 parts of lead per million. It was therefore obvious that no part of the consignment could be passed for human consumption in this country and the question arose whether it was reasonable to put the importer to the expense of sorting it, seeing that even any tins which appeared sound on external examination would not be allowed to be sold in this country because of the lead content. Out of consideration for the importer, whose honesty there was then no known reason to doubt, it was decided to permit him to return the whole of the consignment to the packer on receipt of a guarantee from the packer that the goods would not be returned to any port in the United Kingdom. This guarantee was in due course received from Lisbon through the importer and in early September the goods were checked outward from this port.

It is easy to be wise after the event, but at the time there was no reason to suspect that the course pursued was other than efficient so far as the protection of the public health of this country is concerned and fair and just to the English importer. I was present in the court at the time of the prosecution but was given no opportunity to tender any explanation of the line of action which puzzled the magistrate.

I am, Sir, yours faithfully,

CHAS. F. WHITE,

April 3rd.

Medical Officer of Health, Port of London.

## MICTURITION AND THE PROSTATE

To the Editor of THE LANCET

SIR,—Recent articles in your columns by Dr. Paul Niehans and others regarding the treatment of the enlarged prostate remind us of a leading article in THE LANCET of 1930, ii., 805, on Lord Moynihan's Toronto address. In discussing this address you suggested that "the difficulty in making progress (in natural knowledge) lies not in finding answers to questions but in framing the questions." It seems to us that the time has come to ask "How much and in exactly what manner does the enlarged prostate interfere with micturition?" If the work of Niehans and others is accepted it becomes obvious that current theories of the physiology of micturition in general and of the pathological physiology of the prostate in particular are inadequate. It is, we think, generally admitted by physiologists that there are lacunæ in our knowledge of the physiology of micturition, but it is our impression that surgeons have been too complacently satisfied as to the manner in which "prostatism" interferes with micturition.

Our results in a small series of cases fully bear out Dr. Niehans's claims. Our earlier technique was less simple than that of the Steinach II. ligature and we have abandoned it in favour of Niehans's simpler method. But it is a humiliating and mortifying fact that we were encouraged to try the method because we had examined post-operatively patients operated upon by a surgeon in this country whose methods of attracting patients to himself are not those sanctioned by the profession. We are not acquainted with the surgeon referred to but we understand that since 1917 he has performed his operation over 8000 times and it is common knowledge that he is operating upon an average of ten patients per day at the present time. Here, if you please, is a mass experiment!

We were at a complete loss for even a partial scientific explanation of the good results prior to the publication of Niehans's article in your columns. The results seemed to be too uniformly successful to be explained upon the basis of the well-known remissions and exacerbations of "prostatism." Further, in none of our cases has the prostate appeared to decrease in size though micturition is free and the residual urine diminished or even abolished. In your annotation (Feb. 22nd, p. 439) you comment on Dr. W. E. Lower's results as follows: "Unfortunately the improvement was almost entirely symptomatic, for the size of the prostate . . . had as a rule not altered." The reply to this comment is the question: "What kills the patient: simple enlargement of the prostate or lack of complete urinary excretion?" Results now being reported indicate the possibility of the two being divorced.

We are, Sir, yours faithfully,

FRANK RIGGALL,

Prairie Grove, Arkansas, March 25th. CECIL RIGGALL.

## GLUCOSE-SALINE IN TOXIC DIPHTHERIA

To the Editor of THE LANCET

SIR,—I have been so impressed by the success of glucose-saline administration in a case of almost hopeless diphtheria that I would like to hear of its trial in our larger fever hospitals. A child of 6 was admitted to my care from a home where two children had already died after a few hours' illness. Although a large dose of diphtheria antitoxin separated the membrane within 36 hours, serious symptoms

rapidly developed. Vomiting persisted to such an extent that the child's systolic pressure fell to 80, and in spite of rectal glucose-saline she became so dehydrated as to appear moribund. At this stage an intravenous saline with 2 per cent. glucose was tried with success which led to complete recovery.

If I had to deal with many such cases I would institute continuous intravenous drip as a routine, giving 2 per cent. glucose-saline by the apparatus suggested by Farquharson, and using the internal saphenous vein near the ankle so as to control the apparatus at the foot of the bed. The piercing of the rubber tubing by the serum needle would provide ready access for antitoxin in whatever dose or doses it is thought desirable. Atropine, strychnine, adrenaline, or other drugs could be readily administered by the nurse through the same channel; and the continuous drip of 20 to 30 drops of the solution per minute could be continued until all danger of toxæmia had passed.

I am, Sir, yours faithfully,

GILBERT BURNET,

Medical Superintendent, Isolation Hospital,  
Hemel Hempstead.

April 4th.

\* \* \* The value of glucose in toxic diphtheria is recognised by two at least of the medical superintendents of London fever hospitals. Last year in our own columns Dr. N. D. Begg wrote (1935, i., 484): "Antitoxin intravenously and intramuscularly, and dextrose intravenously and by mouth, are accepted as the basis of treatment in diphtheria"; and Dr. E. H. R. Harries wrote (1935, i., 1341): "In the toxic case prognosis, immediate and remote, is definitely improved by the exhibition, in addition to antitoxin, of glucose at first intravenously, and then, for the next ten days at least by mouth."—Ed. L.

## INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 28TH, 1936

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2260; diphtheria, 1171; enteric fever, 13; pneumonia (primary or influenzal), 1286; puerperal fever, 46; puerperal pyrexia, 115; cerebrospinal fever, 35; acute poliomyelitis, 5; acute polio-encephalitis, 1; encephalitis lethargica, 7; dysentery, 41; ophthalmia neonatorum, 90. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 3rd was 6843, which included: Scarlet fever, 984; diphtheria, 1070; measles, 3302; whooping-cough, 693; puerperal fever, 16 mothers (plus 10 babies); encephalitis lethargica, 282; poliomyelitis, 5. At St. Margaret's Hospital there were 25 babies (plus 10 mothers) with ophthalmia neonatorum.

*Deaths.*—In 121 great towns, including London, there was no death from small-pox, 1 (1) from enteric fever, 104 (38) from measles, 7 (1) from scarlet fever, 32 (7) from whooping-cough, 35 (6) from diphtheria, 57 (17) from diarrhoea and enteritis under two years, and 79 (12) from influenza. The figures in parentheses are those for London itself.

The mortality from measles is now falling, the figures for the last eight weeks (working backwards) being 104, 114, 105, 84, 88, 78, 58, 34 for the country as a whole, and 38, 62, 58, 47, 38, 18, 14, 13 for Greater London. Liverpool reported 9 deaths, Leeds 6, Acton, Croydon, Dagenham, Gateshead, Manchester, York, and Birmingham each 3; no other great town more than 2. Liverpool and Birmingham each reported 4 deaths from whooping-cough, no other great town more than 2. Deaths from diphtheria were reported from 22 great towns, 3 each from Luton and Birmingham.

The number of stillbirths notified during the week was 288 (corresponding to a rate of 45 per 1000 total births), including 43 in London.

## OBITUARY

**DAVID MACKAY CASSIDY, M.D., D.Sc.,  
F.R.C.P. Edin.**

Dr. David Cassidy, who died at Salisbury on April 3rd in his ninetieth year, was son of Lieut.-Col. T. Cassidy of the Army Pay Department, and the eldest of three brothers, all of whom entered the medical profession. During his boyhood his father was stationed in Canada, and David began his medical studies at McGill College, Montreal, of which university he was at the time of his death the oldest

[Photograph by Wynspear Herbert

DR. CASSIDY

graduate. It was a great disappointment to him that ill-health prevented him from travelling to Montreal in 1925 in order to accept the honorary degree of LL.D. which the University of McGill then offered to confer upon him. After graduating in Canada he went to Edinburgh University, where he obtained the degrees of M.D., D.Sc. (Public Health), and the F.R.C.P. From the outset of his career he was interested in psychiatry, and soon after leaving Edinburgh he became assistant medical officer at the Inverness county asylum. He was regarded as a young man of exceptional brilliance, as will be manifest from the fact that at the early age of 25 he was appointed deputy medical superintendent under Dr. Wm. Orange at Broadmoor. Five years later, in 1876, he became medical superintendent to the county asylum at Lancaster, one of the largest institutions of its kind in the Kingdom. This important post he held with distinction for a period of no less than 50 years, for, at the earnest request of his committee, he did not retire until the year 1926, at the age of 79. He was a progressive administrator, for he was a pioneer in the introduction of female nurses for male mental cases, and Lancaster was one of the first mental hospitals to be equipped with a pathological laboratory and an X ray installation. In recognition of his work at Lancaster he was created C.B.E. in 1925.

Dr. Cassidy married Miss Helen Angus, who predeceased him. He leaves three daughters and two sons, both of whom are members of the medical profession.

**NORMAN HALIBURTON HUME, M.B. Durh.**

Dr. Norman Hume, who died at Brecon on March 29th, had a distinguished career in the Indian Medical Service before settling in Wales 15 years ago. Born in Newcastle-upon-Tyne, he was educated at the preparatory school there and at Uppingham, returning to Newcastle for his medical course which he completed at the London Hospital, graduating M.B. Durh. in 1904, the same year as his brother (Prof. W. E. Hume) graduated at Cambridge. He joined the I.M.S. two years later, was at first medical

officer of the 2nd Rajput Light Infantry at Secunderabad, and later superintendent of jails. He was employed during the war on the Afghan frontier, being invalided with pneumonia and empyema. Later he was administrator and surgeon at the General Hospital, Calcutta, where he gained much surgical experience. On retiring with the rank of captain in 1921 he joined the late Dr. T. P. Thomas in practice at Brecon, and on his death in 1930 remained in partnership with Dr. D. L. Lees and Dr. David Kyle. His surgical record gained him the appointment of surgeon to the county hospital, where his operation list was frequently comparable to that at any general hospital. His surgical opinion was widely sought in the neighbourhood; he was surgeon to the King Edward VII. Memorial Sanatorium at Pontywal, and recently medical officer to Christ College, Brecon. Dr. Hume was a keen sportsman, using his scanty leisure mostly in fishing.

**MONTAGU DAVID EDER, B.Sc. Lond.,  
M.R.C.S. Eng.**

Dr. Eder, who died in London on March 30th, was a leading figure in the Zionist movement and well known for his researches into analytical therapy. Born in London in 1868, the son of David W. Eder, he was educated in Brussels, took the London B.Sc. in 1891, and then entered St. Bartholomew's Hospital as a medical student, qualifying with the conjoint diploma in 1895. He held for a time appointments in educational and sanitary services, became an active member of the Fabian Society, and being able to travel extensively used his opportunities to make close study of methods of psycho-analysis in use in many foreign centres, pursuing lines of investigation that might lead to the better territorial and political establishment of the Jewish race. For a time he lived in Palmira, Colombia, and was later appointed surgeon to the Bolivian Government. Returning to England he took up analytical therapy as a specialty and was the first secretary of the British Psycho-analytical Society. Becoming physician to the London Clinic for Psycho-analysis, his kindly disposition and outstanding desire to help his patients found full expression in his psychological work. He wrote much in scientific journals, and made useful communications to international congresses of medicine. For a time he was joint editor of *School Hygiene*. He translated Freud on Dreams and Jung on Studies in Word Association.

Dr. FRANK ERNEST GUNTER, who died on April 2nd at Rochester, was born in 1869, educated at Edinburgh University and the Middlesex Hospital, and qualified in 1891, becoming M.D. Edin. in 1923. He joined the R.A.M.C. in 1895, became major in 1907, and was temp. col. while A.D.M.S. of a division in 1916. He became a specialist operating surgeon and in 1917 he was awarded the D.S.O. After his retirement from the Army in 1918 he joined the staff of the Margaret-street Hospital, and became specially interested in the use of tuberculin both in phthisis and in asthma. For some time past he had been chief medical referee to the Sun Life Assurance Company of Canada.

Dr. WILLIAM TURNER, M.V.O., who died in an Edinburgh nursing-home, was for more than 30 years surgeon to the Colonial Hospital at Gibraltar. Born at Keith, Banffshire, in 1856, the son of Dr. Robert Turner,

he graduated M.A. at Aberdeen before studying medicine at Edinburgh, where he took his M.B., C.M. in 1879 and M.D. two years later. After holding resident hospital posts he was for some time assistant in general practice until his appointment at Gibraltar in 1882. There he was also medical officer to the asylum and prison, and chief medical adviser to the Colonial Government. He had also an extensive general and consulting practice in Algeciras. He took the L.M.S. Madrid in 1913. From 1914-19 he was principal medical officer at Milton Hill war hospital, Berks. Dr. Turner was a fellow of the Royal Geographical Society and the author of various articles on conditions at Gibraltar. After his retirement he travelled round the world.

Colonel JOSEPH MACNAUGHTAN CHRISTIE, who died in London on March 31st, had practised for many years at Wanganui, New Zealand. Born in 1871, son of John Christie of Glasgow, he qualified M.B. Glasg. in 1893, M.D. four years later, and F.R.C.S. Edin. in 1898. After serving as surgeon to the Anchor Line he settled in New Zealand, becoming surgeon to the New Plymouth and Wanganui hospitals. On the outbreak of war in 1914 he joined the N.Z. Medical Corps, served in the Hospital Ship *Maheno*, and was appointed consulting surgeon to the Forces. In 1919 he was created C.B.E. (Mil.) and returned to New Zealand as president of the medical appeal board. When all the troops had been repatriated Dr. Christie settled in London, where he maintained his interest in New Zealand affairs. He married Miss V. A. M. Bayley, of New Plymouth, Taranaki, N.Z.

## THE SERVICES

### ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. (reted.) F. G. H. R. Black to rank of Surg. Capt. (reted.).

Surg. Comdrs. R. K. Shaw to *Drake* for R.N.B., and A. L. McDonnell to *Drake* for Devonport Dockyard.

Surg. Lt.-Comdr. (D.) D. Barker and Surg. Lt. F. W. A. Fosbery to *Pembroke* for R.N.B.

Surg. Lt. (D.) A. McD. Watson to *Woolwich*.

### ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdr. C. C. Ungley and Surg. Lt. H. A. Lockhart transferred from List 2 to List 1 of the Tyne Division.

Surg. Sub-Lts. T. D. R. Aubrey and P. M. Inman promoted to Surg. Lts.

### ROYAL ARMY MEDICAL CORPS

Maj. C. A. Hutchinson retires on ret. pay.

Capt. R. A. M. Humphrey retires receiving a gratuity.

Short Service Commissions: Lt. I. U. Young to be Capt.

### REGULAR ARMY RESERVE OF OFFICERS

Maj. L. C. Hayes ceases to belong to the Res. of Off. on account of ill-health.

### TERRITORIAL ARMY

Capt. Graeme Gibson Talbot (New Zealand Med. Corps) and Lt. D. R. Hood to be Capts.

R. J. Kellar (late Offr. Cadet, Edinburgh Univ. Contgt. (Med. Unit), Sen. Div., O.T.C.) to be Lt.

Capt. A. Pain to be Maj.

W. G. Love (late Offr. Cadet, Edinburgh Univ. Contgt. (Med. Unit), Sen. Div., O.T.C.) to be Lt.

### TERRITORIAL ARMY RESERVE OF OFFICERS

Capt. R. P. Anderson, M.C., relinquishes his commn. and retains his rank.

### ROYAL AIR FORCE

Flight Lt. W. Hall is transferred to the Reserve, Class D.

Flying Offr. C. F. R. Briggs to No. 1 School of Technical Training (Apprentices), Halton.

### INDIAN MEDICAL SERVICE

The promotion to rank of Maj. of the undermentioned officers is confirmed: S. P. Joshi and J. L. Donnelly.

Lt. (on prob.) J. F. A. Forster to be Capt. (on prob.).

Capt. R. L. Raymond is confirmed in his appointment.

Maj. A. L. Robb, Medical Officer at Army H.Q., reverts to the home establishment and vacates his appointment after three months' summer leave.

Indian Medical Department: Lt. (Sen. Asst. Surg.) S. D. Rieley retires.

The notification in the *Gazette* of May 10th, 1935, regarding the appointment of Lts. Harbans L. Khosla, Nisar Mohammad Durrani, Suraj Prakash Wanchoo, Sharad Chandra Misra, and Shri Rameshwar is cancelled (*vide* THE LANCET, May 18th, 1935, p. 1184).

### COLONIAL MEDICAL SERVICE

The following appointments have been made:— Medical Officers: Dr. W. S. Davidson, West Africa; Dr. K. J. Gilchrist, Gibraltar; and Dr. J. O. Poynton, Malaya; Dr. W. R. Logan, Assistant Medical Superintendent, Mental Hospital, Singapore. Dr. W. E. Glover becomes Deputy-Director of Medical Services, Nigeria, and Miss M. Gosden Pathologist, Medical Department, Trinidad.

### DEATHS IN THE SERVICES

Major-General JAMES BARNETT WILSON, who died on April 1st at Broughshane, co. Antrim, was born in 1862, and educated at Queen's College, Belfast, and Edinburgh University, qualifying M.D. in 1883. Entering the R.A.M.C. in 1886 he became colonel in 1915, major-general in 1918, and retired in 1921. He served on the North-West Frontier of India 1897-8 (medal with clasp), in South Africa, 1901-2 (Queen's medal with five clasps), and in the war 1914-18 as asst. director of medical services. He was mentioned in despatches and was created C.M.G. in 1916 and C.B. (Mil.) in 1918. From 1904-1909 he occupied posts in Egypt and from 1912-14 was senior medical officer in Jamaica. He married in 1895 Kathleen Dorothea, daughter of Captain David Aird, R.N., and had two sons, of whom the younger is Capt. D. A. O. Wilson, R.A.M.C.

### BRITISH POSTGRADUATE MEDICAL SCHOOL

An intensive course, intended primarily for practitioners, will be held at this school from May 4th to 16th (10.30 to 4.30 daily). Among those giving lectures and demonstrations will be Prof. F. R. Fraser, Mr. St. J. D. Buxton, Sir Maurice Cassidy, Mr. Zachary Cope, Dr. F. G. Chandler, Sir Thomas Dunhill, Mr. Bright Banister, Dr. E. Mapother, Mr. J. P. Hosford, Prof. Leonard Findlay, Mr. A. J. Watson, Mr. Charles Donald, Dr. R. T. Brain, Dr. Janet Vaughan, Dr. E. H. R. Harries, Prof. James Young, and Dr. D. T. Davies. Sessions will also be held at the Royal London Ophthalmic Hospital, the National Hospital, Queen-square, the Central London Throat, Nose, and Ear Hospital, and the Hospital for Sick Children, Great Ormond-street. Early application for membership of this course is recommended, and further information may be had from the dean of the school, Ducane-road, London, W.12. Similar courses will also be held from June 8th to 20th, July 6th to 18th, Sept. 21st to Oct. 3rd, and Oct. 26th to Nov. 7th.

On Mondays from April 20th to July 6th at 3.30 p.m. lectures on recent advances in gynaecology will be given by the following: Dr. J. M. Robson (female sex endocrinology), Mr. Frank Cook (dysmenorrhœa), Prof. R. W. Johnstone (hormone therapy in gynaecology), Mr. Wilfred Shaw (irregular uterine hæmorrhage), Mr. V. B. Green-Armytage (sterility), Prof. W. Fletcher Shaw (genital prolapse), Mr. Bright Banister (fibromyoma of uterus), Mr. Victor Bonney (carcinoma of uterus), Miss Louisa Martindale (radiation therapy in gynaecology), Prof. Miles Phillips (neoplasms of the ovary), and Mr. L. Carnac Rivett (inflammatory diseases of tubes and ovaries). Applications for this course should reach the dean by April 14th.

On Thursdays from May 7th to June 11th at 2.30 p.m. Sir Henry Gauvain will give six lectures on surgical tuberculosis, and from May 21st to June 25th at 3 p.m. Dr. R. A. Young will lecture on non-tuberculous pulmonary diseases.

## PARLIAMENTARY INTELLIGENCE

### NOTES ON CURRENT TOPICS

#### Public Health Bill

IN the House of Lords on Thursday, April 2nd, Viscount GAGE moved the second reading of the Public Health Bill. He said that it represented a further stage in the task of consolidating and bringing up to date the Statutes for whose administration the Ministry of Health were responsible. The Bill was based on the work of a Departmental Committee appointed in 1929 under the chairmanship of the late Lord Chelmsford. The first result of the labours of that committee was the Local Government Bill passed in 1933. After the death of Lord Chelmsford the committee continued its work under the chairmanship of Lord Addington and proceeded to consider the second part of its task—namely, the law of public health. The possibility of producing a single Bill dealing with the whole of the law on this subject was considered by the committee, but they came to the conclusion that such a Bill would run to the quite unmanageable length of about 1000 clauses and that the balance of advantage lay in the preparation of a series of Bills not exceeding 350 clauses each.

The present Bill represented the first of the series and dealt with provisions of a strictly public health character, relating principally to sanitary matters and to the prevention and treatment of disease. Other and later Bills would deal with such topics as streets, open spaces, markets, and food. In the main the clauses of the Bill were a re-enactment of the great Public Health Act of 1875 and of amending Acts passed in 1878, 1885, 1890, 1907, 1921, and 1925; but in addition a number of Acts such as the Notification of Births Acts of 1907 and 1915, and the Maternity and Child Welfare Act, 1918, which dealt with public health matters but did not technically form part of the public health code, had been re-enacted. The Bill did not deal with London, whose public health administration was founded on separate Statutes, except as regarded a few matters in which the London County Council had asked for the Bill to be applied to their area. The fact that the Bill repealed in whole or in part some 30 to 40 Acts of Parliament and substituted 334 clauses for something like 600 sections on the existing legislation was a measure of the simplification which it achieved.

The Bill, like the Local Government Bill of 1933, combined consolidation with a limited amount of amendment. The opportunity had been taken to clear up a number of points on which the law had been notoriously obscure and unsatisfactory, the chief of these being perhaps the question of the vesting of sewers and the relation between sewers and combined drains. Another important clarification which the Bill sought to effect related to the right of appeal against orders, requirements, and other decisions of local authorities. It was plainly necessary that a Bill of this size and importance should be subjected to a close scrutiny by Parliament and the Government therefore proposed to adopt the course taken with the Local Government Bill of 1933 and to invite the two Houses of Parliament to appoint a Joint Select Committee to undertake a detailed examination of the Clauses. It was hoped that the committee might begin its work shortly after the Easter recess and that it might thus be possible for the Bill to reach the Statute Book in the present session. It was not the aim of the Bill to lay down a perfect public health code, but rather to gather together for the first time in orderly and intelligible shape the whole of the law relating to the matters with which it dealt, and thereby to provide a firm foundation and starting point for any necessary future legislation.

After further debate, the Bill was read a second

time. Viscount GAGE then moved that it be referred to a Joint Committee of both Houses of Parliament, and the motion was agreed to.

#### HOUSE OF COMMONS

WEDNESDAY, APRIL 1ST

#### Use of Margarine in Royal Air Force

Mr. LEACH asked the Under-Secretary of State for Air if he was aware that at least 14 county councils and 24 large municipalities had lately abandoned margarine for butter in their homes, hospitals, and public assistance institutions; that many of them already noted an improvement in the health and happiness of the inmates since tinned milk and margarine were given up; that the dietary practices of the defence forces' authorities were now falling seriously behind those of the local authorities; and if he, in the interests of the Air Force would make this reform in diet.—Sir P. SASSOON replied: The present arrangements in regard to the supply of margarine are under review. No decision has yet been reached.

#### Medical and Psychological Treatment of Offenders

Mr. TURTON asked the Home Secretary whether, with a view to making appropriate provision for the accommodation of such cases, he would issue a circular to magistrates asking them to give an estimate of the number of cases each year that came before them where medical or psychological treatment, as recommended by the departmental committee on persistent offenders, would in their opinion be of value.—Mr. GEOFFREY LLOYD, Under-Secretary, Home Office, replied: I am afraid it would not be practicable to obtain in the manner suggested estimates which would be of value. The question whether a particular offender is suitable for treatment of the kind indicated is often one of difficulty and may require skilled investigation over a considerable period. It would be impossible to obtain from each of the 1000 courts of summary jurisdiction estimates framed on a common basis or forming a reliable guide to the probable number of offenders for whom some form of medical or psychological treatment would be appropriate.

Mr. TURTON: As it is now nearly four years since the committee reported and made this recommendation, will my hon. friend take into account that fact and the grave dissatisfaction which exists at the delay in carrying it out?

Mr. LLOYD: The Home Secretary has sent a circular to the courts. It may have arrived at different times, but there is no reason to suppose that the courts are not acting on it.

THURSDAY, APRIL 2ND

#### Aliens and Medical Practice in Britain

Mr. CHARLES TAYLOR asked the Home Secretary whether he was aware that certain alien refugees who were permitted to reside in this country for the purpose of obtaining British medical qualifications were taking up appointments in this country; and what steps he proposed to take to stop this practice, in view of the undertakings given by the Home Office.—Mr. G. LLOYD, Under-Secretary, Home Office, replied: Since March of last year refugees who have applied for permission to reside in this country for the purpose of medical study have been informed that permission can only be granted on the clear understanding that after qualifying they will not be allowed to establish themselves in medical practice in the United Kingdom, but will be expected to leave the country; but amongst the refugee doctors who came here before that date there is a limited number to whom it has been thought right on various special grounds to grant permission to practice in this country after they have obtained a British medical qualification and been admitted to the British Medical Register. The number of cases in which such permission has been granted is 148.

Mr. TAYLOR: Could the hon. gentleman say what are these special cases?

Mr. LLOYD: In some cases of eminent medical men having special attainments their colleagues in this country have asked for them to be allowed to practise here.

Mr. WATKINS: Does that reply mean that those who are not regarded as special cases are by the action of the Government forced to go back to Germany and suffer the persecution that is involved?

Mr. LLOYD: No, Sir, not necessarily, but the hon. Member will appreciate the Government have to consider first of all the interests of British subjects.

Mr. DALTON: Would it not be possible to send some of these people to Palestine where their services are badly needed?

Mr. LLOYD: My information is that there is already a surplus of doctors in Palestine.

#### Bristol Prisoner's Defiance of Medical Officer

Mr. BEVAN asked the Home Secretary if he was aware that George Berry, serving a sentence of three years at Horfield prison, Bristol, after being in the punishment cell on bread and water for several days, refused to go out for exercise on the ground that he felt too weak, and that on his refusal two officers assaulted and beat him; whether the complaints made by the prisoner were recorded in the appropriate books on his appeals to the visiting magistrate, the doctor, and inspector or commissioner of prisons; and whether he would make a full inquiry into the case.—Mr. GEOFFREY LLOYD replied: I presume that the hon. Member is referring to an incident which occurred on Jan. 18th when the prisoner in question refused to go to outdoor exercise though the medical officer recommended that he should do so. It is quite untrue that two officers assaulted and beat him. When they ordered him to put his shoes on and to go to exercise he declined to do so, and on their attempting to put on his shoes he at first resisted violently, but eventually desisted and went to exercise at which he was quiet and well behaved. My right hon. friend had before him at the time reports on the matter, and is satisfied that all complaints made by this prisoner have been properly investigated and recorded. A prisoner has the right not only to petition the Secretary of State, but to make representations to the visiting committee which is an independent body of local justices; and this prisoner was interviewed at the time by one of the visiting justices.

#### Radium Supplies

Mr. ROSTRON DUCKWORTH asked the Minister of Health whether his attention had been called to the statement by the Radium Commission that the present condition of radium supplies in the country presented a serious problem; and whether any steps could be taken to increase the supply of this commodity for the benefit of the hospitals.—Sir KINGSLEY WOOD replied: My hon. friend refers, I assume, to the sixth annual report laid before the National Radium Trust by the Radium Commission. I am informed that the Trust have the report now under consideration, but that they are not yet in a position to make a statement as to their proposals.

#### Cost of Patients at Pension Hospitals

Mr. MAXTON asked the Minister of Pensions the cost per head of maintaining patients at the hospitals of the Ministry at Cosham, Hants, and Erskine House, Renfrewshire, respectively; and what were the proportions of that cost due to administrative charges, medical attention, and to food.—Mr. R. S. HUDSON replied: The cost at the Ministry Hospital at Cosham is 8s. per patient per day, but precise analysis of the expenditure cannot be prepared on the lines desired. The Princess Louise Scottish Hospital for Maimed and Limbless Sailors and Soldiers at Erskine House is not maintained by the Ministry and no information is therefore available as to the analysis of cost. The cost to the Ministry of its own patients in this hospital is about 7s. 8d. per head per day.

MONDAY, APRIL 6TH

#### Panel Practitioners and Clerical Assistance

Commander OLIVER LOCKER-LAMPSON asked the Minister of Health if he was aware that doctors with large panel practices were overburdened with the clerical work involved in registering their patients and filling forms, &c.; and whether, as this non-medical work

adversely affected the capacity of doctors to cure, as well as injuring their health, he would take steps to make a small grant to doctors with large panel practices in order to enable them to afford clerical assistance.—Mr. SHAKE-SPEARE replied: My right hon. friend is not aware that insurance doctors are overburdened with the clerical work to which my hon. friend refers. Account was taken of this necessary part of their work when their capitation fee was fixed.

#### Ex-Service Men and Eye Affections

Mr. GROVES asked the Minister of Pensions the number of Service men who were blinded in, or as a consequence of, the Great War.—Mr. R. S. HUDSON replied: The total number of cases of eye affection due to war service which have at any time been pensioned at 100 per cent. is approximately 2500.

## Medical Diary

### SOCIETIES

- ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.  
FRIDAY, April 17th.  
*Clinical.* 5.30 P.M. (Cases at 4.30 P.M.) Cases, already shown, whose subsequent history is instructive.  
*Radiology.* 8.15 P.M. Dr. Peter Kerley: Emphysema. Dr. Maurice Davidson, Dr. J. V. Sparks, and Dr. H. V. Morlock will also speak.
- NORTH-WEST LONDON MEDICAL SOCIETY.  
TUESDAY, April 14th.—8.30 P.M. (Royal Veterinary College and Veterinary Research Laboratories, Great College-street, N.W.). Address by Sir Frederick Hobday.
- LONDON JEWISH HOSPITAL MEDICAL SOCIETY.  
THURSDAY, April 16th.—4 P.M. (B.M.A. House, Tavistock-square, W.C.), Dr. Robert Hutchison: Constitutional Medicine.
- NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.  
WEDNESDAY, April 15th.—9 P.M. (Royal Northern Hospital, Holloway-road, N.), Clinical Meeting.
- LECTURES, ADDRESSES, DEMONSTRATIONS, &c.
- UNIVERSITY OF BIRMINGHAM.  
FRIDAY, April 17th.—3.30 P.M. (Queen's Hospital), Mr. Douglas Marsh: Demonstration of Ear, Throat, and Nose Cases.
- UNIVERSITY OF GLASGOW.  
WEDNESDAY, April 15th.—5 P.M. (Tennent Memorial Building, Church-street), Prof. Brückner: Physiological Optics and their Relation to Clinical Ophthalmology, and Special Clinical Ophthalmological Problems.
- BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane-road, W.  
WEDNESDAY, April 15th.—Noon, clinical and pathological conference (medical). 2.30 P.M., clinical and pathological conference (surgical).  
THURSDAY.—2.15 P.M., Dr. Duncan White: radiological demonstration. 2.30 P.M., Dr. W. S. C. Copeman: Arthritis. 3 P.M., Dr. Chassar Moir: Operative Obstetrics.  
FRIDAY, 2.15 P.M., Dr. A. A. Davis: gynaecological pathology. 3.30 P.M., Dr. Alan Moncrief: Hygiene of the New-born Child 5 P.M., Sir James Walton: The Surgical Aspects of Dyspepsia.  
Daily, 10 A.M., to 4 P.M., medical clinics, surgical clinics, or operations, obstetric and gynaecological clinics or operations.
- FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.  
SATURDAY, April 18th, and SUNDAY.—All-day course at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E. (Open only to members of the Fellowship.)
- GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.  
WEDNESDAY, April 15th.—4.15 P.M. (Western Infirmary), Dr. J. G. Macgregor-Robertson: Venereal Disease in Men.

JOURNÉES MÉDICALES DE PARIS.—The third of the congresses known as Journées Médicales de Paris will be held next year from June 26th to 30th at the time of the International Exhibition under the presidency of Prof. A. Carnot. The object of these meetings is to bring together doctors in civil and military practice, pharmacists, veterinary surgeons, biologists, physicists, and chemists, both French and foreign. The general subject of discussion will be Hormones and Endocrine Therapeutics, and particulars may be obtained from the Service des Journées Médicales, *Revue Médicale Française*, 18 rue de Verneuil, Paris, VII.

## MEDICAL NEWS

**University of Glasgow**

On Mondays, Wednesdays, and Fridays from April 15th to 27th Prof. Brückner, of Basle, will deliver six lectures in the ophthalmic department of the university on physiological optics and their relation to clinical ophthalmology and on special clinical ophthalmological problems. The lectures will begin at 5 P.M.

**University of Aberdeen**

On April 1st the following degrees and diplomas were conferred:—

*M.D.*—\*John Findlay and \*M. McI. Milne.

\*With commendation.

*M.B., Ch.B.*—A. A. N. Bain, L. G. Boyd, J. G. Byth, J. S. Cruickshank, Louis Findlay, Margaret A. Hay, and William Wilson.

*D.P.H.*—Hugh Morrison and M. J. Schultze.

**British College of Obstetricians and Gynaecologists**

A meeting of the council of the College was held in Belfast on April 1st, with Sir Ewen Maclean, the president, in the chair. Mr. Eardley Holland was appointed to represent the College on the committee of the Eugenics Society which is considering population problems, and Dr. Douglas Miller (Edinburgh) was appointed representative at the forthcoming French Congress of Gynaecology.

S. L. Navaratnum and G. A. W. Wicknamasuriya were elected members of the College.

At a special meeting of the council held on April 2nd the following were formally admitted to the fellowship:

Alexander Ernest Chisholm (Dundee), John Francis Cunningham (Dublin), Margaret Fairlie (Dundee), and John Gardner and Robert Aim Lennie (Glasgow).

The following were admitted to the membership:

A. J. S. L. Boyd, R. B. Charlton, Mildred I. Ealing, Stanley Henderson, C. R. MacDonald, J. S. MacVine, T. N. MacGregor, S. D. Meares, Elizabeth M. Moore, T. R. Plunkett (in absentia), A. W. Purdie, Edward Solomons, and W. R. Winterton.

At the annual general meeting which followed Mr. Bright Banister, Prof. Daniel Dougal, Dr. Theodore Haultain, and Mr. Henry Greer were elected to the council as representatives of the fellows, and Mr. G. F. Gibberd and Dr. Douglas Miller as representatives of the members. Sir Ewen Maclean was elected a trustee in place of the late Prof. W. Blair-Bell.

**International Congress of Orthopaedic Surgery**

The third congress of the International Society of Orthopaedic Surgery will be held at Bologna from Sept. 21st to 24th, and in Rome on Sept. 25th, under the presidency of Prof. Putti (Italy). There will be discussions on internal derangements of the knee and on arthrosis in the sequels of infantile paralysis. Mr. H. A. T. Fairbank is vice-president of the congress, and the speakers in the first discussion will include Mr. Harry Platt. The secretary-general is Dr. Delchef of Brussels.

**Fellowship of Medicine and Post-Graduate Medical Association**

The following courses will be given during this month: proctology at St. Mark's Hospital (all day, April 20th to 25th); ophthalmology at the Royal Eye Hospital (afternoons, April 20th to May 1st); medicine, surgery, and gynaecology at the Royal Waterloo Hospital (all day, April 27th to May 9th); psychological medicine at the Maudsley Hospital (afternoons, April 27th to May 30th). In May courses will include: dermatology at St. John's Hospital (afternoons, May 1st to 29th); thoracic surgery at the Brompton Hospital (all day, May 11th to 16th); urology at St. Peter's Hospital (all day, May 18th to 30th); proctology at the Gordon Hospital (all day, May 25th to 30th); venereal diseases at the London Lock Hospital (afternoons, May 25th to June 20th). Week-end courses will be held during April and May as follows: heart and lung diseases at the Victoria Park Hospital (April 18th and 19th); infants' diseases at the Infants Hospital (May 2nd and 3rd); chest diseases at the Brompton Hospital (May 9th and 10th); surgery at the Cancer Hospital (May 16th and 17th). Courses arranged by the fellowship are open only to members and further information may be had from the secretary of the fellowship, 1, Wimpole-street, London, W.

**Central Midwives Board**

Sir Comyns Berkeley, F.R.C.P., has been elected chairman of the Central Midwives Board in succession to Dr. J. S. Fairbairn, who has retired from the Board.

**Medical Research Council**

Mr. Richard K. Law, M.P., has been appointed a member of the Medical Research Council, in the vacancy caused by the retirement of Mr. W. S. Morrison, M.P., on becoming Financial Secretary to the Treasury.

**Army Dental Corps**

The annual dinner of the officers of the Army Dental Corps will be held on Friday, July 24th, at the Connaught Rooms, W.C.2.

**Society for the Study of Inebriety**

The spring meeting of this society has been deferred till Tuesday, April 21st, when it will be held at 11, Chandos-street, London, W., at 4 P.M. After the business meeting Dr. J. D. Rolleston will read a paper on snuff-taking.

**German Radiological Congress**

The twenty-seventh congress of the Deutsche Röntgen-Gesellschaft, which was postponed because of the German elections, will now be held at Wiesbaden from April 23rd to 25th. Further information may be had from Prof. Dr. Frik, Brückenallee 22, Berlin, N.W. 87.

**Course on Chemical Warfare**

Seven lectures and a practical demonstration on air-raid precautions for members of the medical profession and trained nurses have been arranged by the British Red Cross Society. They are to be given on Fridays at 5 P.M. at 9, Chesham-street, Belgrave-square, London, S.W., and the first will be on May 1st. The lecturer is Major H. N. Stafford, R.A.M.C., and further information may be had from the county secretary of the society, 9, Chesham-street, London, S.W.1.

**Pathological Research in Relation to Medicine**

Our advertisement columns contain particulars of a course of lectures on this subject to be given in the institute of pathology and research at St. Mary's Hospital, London, at 5 P.M. on Tuesdays from April 21st to June 9th. The first is by Sir Almoth Wright, F.R.S., principal of the institute, and the other speakers will be Sir Joseph Barcroft, F.R.S., Mr. F. L. Pyman, F.R.S., Dr. J. E. McCartney, Prof. L. J. Witts, Prof. E. N. Andrade, F.R.S., Prof. Grey Turner, and Prof. S. P. Bedson, F.R.S.

**London School of Hygiene and Tropical Medicine**

The annual malaria control course for laymen will be held at this school (Keppel-street, W.C.) from June 22nd to 26th under the direction of Sir Malcolm Watson. On Thursday, July 16th, it is proposed to hold at the school the annual conference for medical officers in industry overseas, the object being that officers on leave from the tropics may be able to meet their colleagues and discuss their problems. The main subject for discussion will be the prevention of disease. Further information about the course and the congress may be had from the organising secretary of the Ross Institute of Tropical Hygiene at the school.

**Association for Moral and Social Hygiene**

Dame Rachel Crowdy, R.R.C., will preside at a public luncheon to be held at the Criterion Restaurant, London, W., on April 23rd to celebrate the fiftieth anniversary of the repeal of the Contagious Disease Acts. The speakers will include Lady Astor, M.P., Mr. R. A. Butler, M.P., and Prof. Gilbert Murray. At 6 P.M. on the same day a service of thanksgiving is to be held at St. Martin-in-the-Fields, when the Bishop of Liverpool will be the preacher, and on April 24th, at 5.30 P.M., Madame Pesson-Debret will address a meeting at the Livingstone Hall (opposite St. James's Park station) on the Fight against Regulation in France. Further particulars may be had from the Association at Livingstone House, Broadway, S.W.1.

a similar swelling, but not so large. The right-sided aneurysm was successfully excised, with complete relief of the pain, but the left, which was causing no symptoms, was left alone.

Bilaterally symmetrical aneurysm has previously been described, and is ascribed to atheromatous changes in the vessels, possibly combined with nervous disturbances. Krull considers that these factors applied in the case he describes.

### THE SERIOUSNESS OF TUBERCULOUS SUPERINFECTIONS

WHEN clinically demonstrable tuberculosis develops in someone who, a few years earlier, had been found to be Pirquet-positive, is his disease a sequel to his primary infection or to a recent superinfection? Many, if not most, of the papers in which an attempt is made to answer this question provide evidence which is so inconclusive that it is a pleasure to discover such weighty arguments as those provided by Dr. J. Heimbeck in a lecture recently given before the Medical Society of Oslo (Nord. med. tidskr., Feb. 15th, 1936, p. 241). It may be said at once that he makes out a plausible case for superinfections as the cause of a goodly proportion of cases of active tuberculosis in persons between the ages of 12 and 38.

The material consisted of 2425 persons with a total observation period of 9903 years. These persons were classed in five groups. Group A consisted of persons of both sexes between the ages of 12 and 19, some living in tuberculous and others in healthy surroundings. Group B included persons between the ages of 20 and 38 unexposed to tuberculosis. Group C included persons of the same age as in group B, but living in tuberculous surroundings. Group D included the nurses of the Ullevaal Hospital in which they were exposed to intensive infection with tuberculosis. Group E included the Ullevaal nurses who became Pirquet-positive as a result of B C G inoculation. The 2425 persons in these five groups were kept under observation with reference to their development of tuberculosis during the 9903 years under review. The tuberculosis they developed was classified in two categories according as it was characteristic of primary tuberculosis (pleurisy or erythema nodosum) or appeared in some other form (pulmonary tuberculosis or pulmonary infiltration) commonly regarded as usually being a comparatively late manifestation of a tuberculous infection. Such a distinction was, of course, rather arbitrary, and Dr. Heimbeck is careful to note that the tuberculous manifestations in his second category may in some cases have been the prompt sequel to a primary infection.

In his first three groups, in which there were 1608 persons kept under observation for a total of 6431 years, there were only 2 cases of tuberculosis in the first category, and 21 in the second. But in group D, represented by 588 nurses, the incidence of tuberculosis was much higher—13 cases in the first category and 14 in the second. In group E (229 nurses) there were 7 cases in the first category, but only 1 in the second. Commenting on these findings, Dr. Heimbeck emphasises the fact that in his first three groups all but two of the cases of tuberculosis belonged to his second category (comparatively late manifestations of tuberculosis). But in group D—originally healthy nurses—there were as many as 13 cases of tuberculosis in his first category and 14 in his second. After considering various possible sources of error in his calculations, he comes to the conclusion that the frequency with which the nurses in group D developed manifestations of tuberculosis indicative of a recent infection must be taken as the measure of the importance of superinfections. As for the nurses in group E—persons inoculated with B C G because a negative Pirquet test had indicated the absence hitherto of a primary infection—it was significant that all but one of the 8 nurses subsequently developing tuberculosis suffered from it in the form of pleurisy or erythema nodosum. Evidently

the benign infection with B C G had in these cases failed wholly to counteract the massive infections to which the nurses had been exposed.

### STATISTICAL POINTERS TO PRACTICE

DURING the past twenty years manufacturers have more and more adopted quantitative methods of measuring their markets and a book<sup>1</sup> lately issued to help them in their task provides valuable information by bringing together from scattered official and unofficial sources statistics of population, of families, of density, of the incidence of social grades, of local prosperity, and so on. The tables are often illustrated by the type of pictorial diagram which leads to the digestion of statistics without much dyspepsia, and the clear presentation of the material, and references to its places of origin, may well lead to the book having a wider circulation than is the authors' immediate aim. For instance, the young medical graduate in two minds as to where to practise might well find hints in its tabulations. The southward trend of population is shown by the fact that between 1921 and 1934 there was an increase of 1½ millions in London and the south-east—an increase equal to the populations of Manchester and Liverpool combined—while Scotland, Northumberland, and Durham had virtually no increase, and Wales actually diminished in population. Parallel with these changes there has been a tendency for the populations of metropolitan centres to move outwards. He who is interested in midwifery or the diseases of childhood will find high birth-rates and a high proportion of children in South Wales, Northumberland, and Durham, and in Scotland. For the same number of patients it appears that the practitioner of to-day—and still more of to-morrow—must have a larger number of families on his visiting list than his predecessor. For in 1921 there were 4·17 persons per family, and by 1934 this had fallen to 3·68. As is well known, the age composition of the population is changing; the number of children is diminishing while the number of adults is still increasing, and every increase in the latter means an increase in small families. By 1941 families of 1-3 persons will, it is estimated, have risen by nearly a million, while those of 6 or more will have fallen by 300,000. Estimates of the numbers of families in different income groups show that the lowest grade, whose chief income-earner receives less than about £4 per week, are proportionately most frequent in Lancashire, Warwickshire, Nottinghamshire, Durham, Derbyshire, and Staffordshire, and least frequent in Sussex, London, Cornwall Middlesex, Surrey, and Devon. We may note in passing an estimate that the total sales of newspapers in Great Britain per 100 families is equivalent to 95 morning, 57 evening, and 130 Sunday papers.

OXYGEN ADMINISTRATION.—We have received a letter from Dr. Argyll Campbell saying that the box mask for administration of oxygen to which he referred in a letter in THE LANCET last week may be obtained in aluminium from Messrs. Siebe Gorman & Co., Ltd., 187, Westminster Bridge-road, London.

TUBERCULOSIS IN MOSCOW: CORRIGENDUM.—In our issue of March 21st (p. 699) we credited Mr. Le Gros Clark with a statement that the Moscow death-rate from tuberculosis has been reduced from 40 per 1000 during the civil wars to less than 12 per 1000 to-day. These rates are (as may be supposed) ten times too high. The figures given by Mr. Clark were 400 and 120 per 100,000—i.e., 4 and 1·2 per 1000.

<sup>1</sup> Home Market, a Handbook of Statistics. By Major G. Harrison and F. C. Mitchell, and the statistical staff of the London Press Exchange, Ltd. London: George Allen and Unwin Ltd. 1936. Pp. 149. 10s. 6d.

NOTTINGHAM HOSPITAL SATURDAY FUND.—This fund for the past year amounted to £28,174, the highest figure reached since its inauguration.

## ADDRESSES AND ORIGINAL ARTICLES

## MALIGNANCY

WITH ILLUSTRATIONS FROM THE  
PATHOLOGY OF THE MAMMA\*

By Sir ROBERT MUIR, M.D. Edin.,

F.R.C.P. Lond. &amp; Edin., LL.D., F.R.S.

PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF GLASGOW

MAY I ask your indulgence if at the outset of my address I refer to a matter which has doubtless presented itself to the minds of you all—the break with precedent which has admitted to the high honour of the Lister award one who is not himself a surgeon? I come before you as in some sort a layman, with a layman's disabilities, but I am fully conscious that in your catholicity of outlook your desire has been to stress the fact that pathology and bacteriology were the base and the essential condition of Lister's work in surgery. I appreciate to the full the signal distinction which has been conferred upon me.

On the occasion of the 109th anniversary of Lord Lister's birth, we are met to do honour once more to his memory. In fulfilling my obligation to give a lecture I should have liked to make the subject Lister's scientific work, but a short time ago I gave an address on this subject to the Canadian Medical Association, and I felt that it would not be justifiable to offer on the present occasion what would necessarily be a repetition in great part of what I had already said. I have had perforce to choose another subject. Before speaking on it I should like to offer a few remarks of a general kind.

Than the life work of Joseph Lister there is in the history of our profession no better example of the truth that advance in practice can come only from increase of knowledge, hardly won by continuous and painstaking investigation. The scientific achievements of the earlier part of Lister's life are naturally overshadowed by his epoch-making contributions to surgery in the latter part, but no one can appreciate how his immortal benefaction to mankind was bestowed without following the steps in his scientific progress. And it is to his earlier years that we must look for a just estimate of his gifts as an investigator. "Science for its own sake" might be said to have been his motto at first, but this was modified as practical requirements arose.

By the time he had gone to Glasgow at the age of 33 he had published more than a dozen papers on subjects histological, physiological, and pathological, several being historical landmarks. In them is apparent that combination of detailed observation and breadth of outlook which marks the master mind. While occupied with minutiae he was ever seeing afar and thinking broadly. He lived both in valleys and on the heights. And if we bear in mind the simplicity of the apparatus at his disposal and also the fact that his investigations were made in the spare time of a busy life, we cannot but marvel at his recorded achievements. Is there anything more pleasing or instructive in the history of research than the picture presented in his biography by Sir Rickman Godlee—the picture of Lister after a day's work was over carrying on his experiments till the early morning hours, spending what he called "a glorious night" in the study of the phenomena of inflammation?

The year 1865 was the turning-point in Lister's life for he then saw the bearing of Pasteur's researches; the fundamental facts regarding fermentation and putrefaction thereafter occupied his thoughts. A principle was grasped by him for the first time and his task then became an endless series of experimental trials, yet a sure evolution towards its successful application. In this his powers and methods to which I have referred are again clearly in evidence. The tale has often been told and is known to you all. In his opening lecture when he went to the chair of clinical surgery in Edinburgh in 1869 he was able to use these words, with confidence yet with modesty, "The germ theory is the pole-star which will guide you safely through what would be otherwise a navigation of hopeless difficulty." It is to me a pleasing thought that after having practically completed his work on antiseptics and having bestowed on mankind the greatest gift it has received, he should have been able once more to follow his bent and devote himself with unabating zeal to more purely scientific problems. His classical paper "On the lactic acid fermentation and its bearings on pathology" is a remarkable example of the outcome. Lister indeed possessed the essential qualities of the ideal investigator.

I close with the words which ended my previous address.

"In Lister's own time there were those who followed him along his way with understanding, expectancy and generous pride. There were those too who knew no more than to accord him a grudging kind of honourable mention when they ought to have sat at his feet. In these our own days, there can be but one attitude, that of veneration, and our veneration goes forth with a personal intensity to the man whose encompassing kindness made all humanity his concern. In him rare gifts and rare goodness met and greeted each other, made a pact of mercy and kept it. In commemorating once more the consecrated work of Joseph Lister we salute the memory of a man great in intellect and in soul, great in aim and achievement, great and humble in triumph."

\* \* \*

In speaking on malignancy I shall keep to very general terms. It would be impossible to discuss the various views with regard to the nature and origin of malignant tumours, and it is not my object to do so. I shall rather state as simply as I can how the subject presents itself to me after a relatively long life as a pathologist. What I have to say falls mainly into three parts. In the first place, I shall speak of our present knowledge of the characters and aetiology of malignancy, as the result of observation and experiment; in the second place, I shall illustrate some of the chief points by my own observations on malignant disease of the mamma; and lastly, I shall briefly consider the essential nature of malignancy.

## Some Features of Malignancy

I have used the term "malignancy" in my title rather than "neoplasia" since it may be taken to indicate the latter in its extreme deviation from normal growth. This entails the disadvantage that simple tumours and the graduated series of growths which may originate from one tissue are not considered, but I do not think the discussion will be seriously affected thereby.

It is unnecessary here to detail the nature of malignancy. In a general way malignancy may be regarded as an abnormal behaviour of cells, consisting

\* The Lister memorial lecture for 1936, delivered before the Royal College of Surgeons of England on April 7th.

essentially in uncontrolled growth. It is evidenced by deviations in cell structure, dedifferentiation or anaplasia and sometimes extreme aberration in type, and it is often characterised by metabolic changes, especially in respiratory functions. But these and other properties are merely indications of changes in the biology of the cells, and do not in any way explain these changes; in other words, they are evidences of altered behaviour. It has been pointed out by others that normal cells will proliferate indefinitely if the conditions are favourable; this is seen in tissue cultures where the cells are free from adjacent tissues. Such cells, however, on being reintroduced into the body are once more restrained by the tissue tension which they encounter. Malignant proliferation, on the other hand, overcomes the controlling influence of the surrounding tissues and continues indefinitely in spite of it; this is most satisfactorily studied in the case of carcinoma. The term "autonomous" is eminently suitable as it implies that the malignant cells are a law to themselves. They invade and destroy the tissues while the latter exert their powers of restraint and are sometimes successful. But the proliferation must not be regarded as all-powerful. Experimental work on transplantation of tumours shows that the margin between growth and non-growth is comparatively narrow, and observation on malignant disease in the human subject supplies numerous examples of malignant cells being overcome and disappearing locally. The actual malignancy is in fact the surplus malignancy against tissue resistance.

While malignant cells are frequently overcome locally by stroma reaction, there is, however, no satisfactory evidence that weakened resistance of connective tissue will in itself lead to malignancy in the related epithelium; although *diminished tissue tension* has been put forward as a factor by various writers. As I have said, we are dealing with a biological change in the cells which is not brought about in this way. Furthermore, the malignant character once acquired seems to be a permanent property of the cells; they may be destroyed or die out, but they do not, so far as we know, regain a normal behaviour. Thus tumours have been transplanted in mice over many years without loss of malignancy. Likewise, tumour cells after having been grown in cultures separate from the other tissues for a time manifest their properties again on introduction into a living animal. I wish to emphasise here that the biological properties of the cells appear to have undergone an essential alteration which is apparently transmitted to their descendants.

With regard to *congenital abnormalities* in relation to malignancy I cannot speak in detail. These are not infrequently the bases of malignant growth—without the abnormality the tumour would not have arisen. Undoubtedly, too, the liability to malignancy varies in different examples of such abnormalities; compare, for example, the high incidence of malignancy in teratoma testis with that in pigmented naevi. Not many naevi originate a malignant melanoma. The incidence of malignancy must be investigated in the case of each abnormality. It is possible that abrogation of function arising from displacement of cells brings with it an increased tendency to malignant proliferation but, as I have said elsewhere, embryonic cells, though energetic in proliferation, are just as much under the laws of controlled growth as those of the adult tissues. And we have clear evidence that in the origin of malignancy in congenital abnormalities irritants and cell stimuli play a part just as in the case of normal tissues.

Undoubtedly the most striking examples of malignant growth in relation to embryonic proliferation are the tumours which arise at the earliest period of life, such as nephroblastoma and sympathicoblastoma. With the exception of the fact that they occur at a period of very active normal proliferation, we know nothing as to their origin.

Some other points may be referred to in this preliminary review; one of these is the *distribution of malignancy* in the human body. Recent investigation has not only revealed more and more the wonderful variations in the structures of tumours but also the multiplicity of cells from which they may arise. One is justified in saying that malignancy may appear in any cell of the body, with one proviso, however, that the cell has the power of normal proliferation. Tumours malignant, as well as simple, arise not only from the tissues most active in repair but also, though less frequently, from the specialised cells—e.g., those of the liver, adrenals, and endocrine glands. An adult nerve-cell, on the contrary, has lost the property of proliferation and no tumour arises from it; but a growth may originate in its progenitor, the neuroblast, and often possesses highly malignant properties. The terms "carcinoma" and "sarcoma" are thus a poor reflection of the varieties of tumours. The origin of malignant neoplasms from highly specialised cells is an important section of the general subject, but so far it has been scarcely touched by experimental methods.

Another matter in relation to the general question is *age-incidence*. Malignancy becomes more frequent as age increases owing to the higher incidence of carcinomata associated chiefly with increasing opportunity for damage, irritation, and other disturbances of the tissues. But malignant growths are met with in the early years of infancy, and there is clear evidence that they may originate during intra-uterine life. Interesting facts with regard to this subject have been gathered in recent papers by Blacklock (1934). Sarcomata of bone too are markedly related to the growth period. The outstanding fact, however, is that from whatever cells, in whatever way, and at whatever age malignant tumours arise, they are essentially similar in their general behaviour and in their conditions of growth. One naturally holds as a working hypothesis that there must be some ultimate disturbance of cell life underlying all the different conditions.

#### Ætiological Factors

When we consider the cause of malignancy, it must be recognised that the subject is of great complexity. In the first place there are the particular circumstances in time which give rise to malignancy—the primary or initial causes. There are also additional circumstances such as the susceptibility of the tissues, especially that which is hereditary; these are equally essential to the occurrence of malignancy. And finally there is the factor of the vital behaviour of the cells, whether this is a continued reaction to some agency or results from some obscure form of nuclear damage. The last question concerns the real nature of malignant proliferation. The matter may be put in the following way. Various irritant and abnormal conditions give rise to malignancy; there are numerous primary causes. But what is the causation of the malignant proliferation, say in a secondary growth, when the cells are beyond the influence of the agency which originally led to its development? Neoplastic proliferation corresponds up to a point with reactive proliferation but it seems to possess in addition a feature all its own.

Looking back on the results of research during recent times, say the last 25 years, one cannot but be impressed by the advance in knowledge of the different ways in which tumours may be initiated. Chronic irritation was the first factor to be recognised, and the cumulative evidence of numberless clinical observations became practically conclusive as to its importance. Then followed the recognition, still from the clinical side, that a number of so-called irritants, strikingly different in their nature, were specially liable to cause the malignant change. The matter was then clinched by experimental work which started with the researches by Fibiger on gongylonema cancer and those of Yamagiwa and Iohikawa on the production of epithelial new growths by tar. Since that time the number of carcinogenic agents has been steadily added to and now they are many in number and variety. I should like to say here that the contributions of workers in this country have been of a distinguished order. Real progress was made when Kennaway (1925, 1930) first established the relation of chemical structure to the carcinogenic property and showed how slight variations in the molecule might be attended by absence or presence of the property. Kennaway's observations and those of Cook and his co-workers (1932) brought out clearly that there is no relationship between irritating effect in the ordinary sense and the faculty to lead to malignancy, and hence raised the possibility of there being some common feature in chemical structure on which the carcinogenic property depends. From these and other observations it would appear, however, that the carcinogenic agents have a special property of stimulating growth or cellular proliferation, whilst other closely allied chemical substances have not this property. "Growth stimulants" rather than "irritants" would appear thus to be the preferable term. The next advance was made by Cook and Dodds (1933) who showed that dibenzanthracene, one of the most active carcinogenic agents, had an oestrogenic effect on mice like that of oestrone or folliculin. In this way a link was made as regards biological effect between a carcinogenic substance and a female sex hormone. Another step of great importance was the demonstration by Lacassagne (1932) that the injection of oestrone is effective in producing adenocarcinoma in the mammae of male mice. These observations will be further referred to.

If I were to attempt to give a summary of the results which have been reached I might put it as follows: (1) By both experimental and observational methods it is shown that malignant growths may be produced by the prolonged action of irritants and cell stimulants. Such growths chiefly affect tissues active in repair. (2) There are malignant growths of the more specialised epithelial tissues and of some connective tissues which have not yet been produced experimentally, but pathological observations in the human subject indicate that they may arise on the same principles. (3) There are malignant growths which can be placed in neither of these two classes. We know nothing as to the conditions incidental to their occurrence and can hardly even speculate as to their causation. Such are the malignant growths arising from embryonic cells, sometimes multipotent; those of the leucocyte-forming tissue; also a great variety of tumours in connexion with the central nervous system, endocrine glands, &c. The methods of experimental embryology may throw light on some of these. The origin of malignancy in relation to normal proliferative processes, however, is a subject on which one can say nothing definite. For

example, while the age-incidence of bone sarcoma indicates its relation to processes of normal growth, it is an instructive fact that bone sarcoma may also arise at a later period of life in relation to abnormal proliferative processes—e.g., those in connexion with generalised osteitis and Paget's disease of bone.

In view of the large number and great variety of chemical and physical agencies which have been shown by clinical and experimental methods to lead to malignancy, one is caused to inquire whether there is any one general principle concerned in the initiation of malignant growth. The nearest approach to a general statement which I think can be made is that the acquisition of malignancy is related to *previous non-neoplastic proliferation*. Sometimes the proliferation may not be continuous, and it is known that malignancy may appear after a person has been removed for some time from the carcinogenic influence; but the fact that the time intervening between its start and the onset of malignancy is comparatively long as a rule cannot be without significance. The occurrence of a long latent or silent period between the initial stimulus and the malignant growth is the rule. But there are exceptions; noteworthy examples are the malignant growths appearing shortly after birth, also chorion-epithelioma at a later period of life. It is interesting, however, that such tumours are related to growth of a very active kind.

I shall not discuss here proliferation following a single trauma in relation to the origin of malignant growths; it is a wide and controversial subject and has recently been treated comprehensively by Ewing (1935), with whom I agree in all essential particulars. On considering the conditions which lead to repeated or continuous cellular proliferation in pathological states we see that they are chiefly of three kinds: (a) chronic irritation, (b) compensatory hyperplasia, and (c) the action of hormones. Something may now be said in exemplification of malignancy occurring in these three conditions.

(a) The term "chronic irritation" must be used in the widest sense. There are cases of carcinoma following long-continued reactive proliferation where nothing is known of the nature of the irritant. Carcinoma of the cervix uteri may be mentioned in illustration. An interesting example of a malignant growth produced by a definite *chemical substance* is that recently discovered by my colleague, Prof. Browning, and his co-workers (1936). The substance in question is a water-soluble styryl compound, chemically unrelated to the carcinogenic substances of Kennaway and others, and an interesting point is that sarcoma has followed a single injection in a large proportion of cases. When injected subcutaneously the dye becomes precipitated in the tissue fluid and minute coloured particles are formed but there is almost no immediate irritant effect. Some months later a perceptible induration is present at the site, and this is due to tissue formation constituted mainly by large masses of phagocytes containing the coloured particles. Later still, rapid growth occurs owing to development of sarcoma which is of the spindle-cell or pleomorphic type. The growth has been transplanted to other mice, in one case ten successful passages have been made. The special features here are the relative lack of initial irritant effect and the very slow growth of the reacting cells up till the time of the appearance of malignancy.

(b) In the second place, reference will be made to malignancy as a sequel to *compensatory hyperplasia*. The importance of this is that *specialised* cells proliferate. There are fewer definite examples of this

but a noteworthy one is met with in the liver. Probably no other organ responds so readily to loss of its substance by compensatory growth; the loss of a third or even half of its bulk experimentally produced, is soon followed by restoration practically to the original weight. The same compensatory process occurs when there is destruction of the liver cells by disease, as in cirrhosis, and then not rarely the compensatory process passes into malignant neoplasia. I studied this and was able to follow the stages (1908). The cells in a hypertrophic focus on acquiring malignancy show alterations both in cytoplasm and nuclear structure. A liver trabecula, which may be regarded as a tubular gland with a bile capillary as its lumen, becomes changed into an elongated mass of cells without lumen, while the cells become altered in appearance. A break through then occurs and a liver-cell carcinoma results. This may happen in multiple foci. To what extent a similar process may occur in growths from other specialised cells is uncertain, but the same principle may hold in the case of endocrine glands. In the thyroid, for example, carcinoma is definitely related to goitre, and this in turn depends upon a succession of processes of hyperplasia and involution.

(c) I shall now say something with regard to malignancy as a sequel to proliferation produced by hormones. A new field of inquiry has been opened up by the work recently done on this subject. The malignant growths thus produced have been in the mamma and, as the results enable us to interpret the changes found in human disease, I shall first describe my observations bearing on the general question.

#### Malignancy in the Mamma

The subject may be arranged under three headings: (a) the development of malignancy in the mamma; (b) the struggle between malignant cells and the normal tissues; (c) the parasite-like behaviour of the cancer cells.

#### DEVELOPMENT

The development of malignancy has been studied in breasts the seat of manifest cystic disease, in those with various conditions of local hyperplasia and fibrosis with little or no cyst formation, and also in those in which actual carcinoma is present. In the last mentioned the non-malignant changes are of special importance in relation to the development of carcinoma. As a result of such study one becomes convinced that there are a whole series of structural changes presenting infinite variety as regards detail, which affect the mammary epithelium and lead up to malignancy. To speak in the most general terms, these are (1) increased and altered secretion accompanied by changes in type of the epithelium, and by desquamation of cells, and (2) hyperplastic proliferation of the epithelium. These are, of course, associated with fibrosis in varying degree. Whilst disordered secretion, leading to distension of ducts and acini, appears often to be the initial change, the degree in which either of the two kinds of epithelial changes predominates varies in different cases. Sometimes cyst formation is the outstanding feature, resulting in the so-called cystic degeneration or Schimmelbusch's disease. More frequently hyperplastic changes predominate and these are of special importance in relation to malignancy. Cheatle (1926, 1931) has already given a full account of the changes and I agree with him on all essential points.

The hyperplasia of epithelium is attended for a long time by a coördinated increase of connective tissue—a condition still removed from malignancy.

Thus there arise papillomatous growths in the ducts and these are often present at an early stage in association with cystic dilatation. The papillomata may be small and numerous or they may reach a considerable size. The well-known duct papilloma, for example, may be associated with relatively large papillomata in the substance of the breast. The next stage is a relative overgrowth of epithelium in comparison with stroma; epithelial outgrowths are now produced which contain only a small amount of connective tissue. This condition passes on gradually to a stage where there is proliferation of epithelium alone and large cellular masses without any stroma are found within the ducts. For a time the epithelial cells, though enlarged, show little alteration in their characters and mitoses are few. Further, the cells retain their polarity to a certain extent; some are columnar and form rings or pseudo-acini in the cell masses (Fig. 1). Occasionally the hyperplasia affects only one side of a duct (Fig. 2). Finally the anaplasia becomes distinct; the cells and their nuclei vary in size, the latter becoming of the vesicular type with distinct nucleoli. The amount and arrangement of chromatin vary and ultimately one finds within the ducts cellular masses which have all the characters of an encephaloid carcinoma (Fig. 3). The term *intraduct carcinoma* may be then applied as we are justified in regarding the cells as malignant although they have not yet passed into the tissue spaces. Such changes may be met with at different stages in the same case and may be accompanied or not by carcinoma.

The statement is not infrequent that intraduct carcinoma is rare. Its occurrence as a widespread condition, giving rise to the so-called comedo masses within the ducts, is relatively uncommon. But local intraduct carcinoma is in my experience quite common, being found in many cases of carcinoma of the breast as well as in cases free from carcinoma. In association with the changes in the ducts a few acini are commonly affected similarly but occasionally there is a growth of malignant cells within the acini over a considerable area. The epithelium of the acini may be entirely replaced by cells of malignant type whilst the structural outlines of the acini are completely retained, a condition of intra-acinous carcinoma. Such a condition may be extensive, whilst alongside there are lobules of normal appearance (Fig. 4). I believe that intraduct carcinoma with or without intra-acinous carcinoma represents a condition where the cells have acquired the characters of malignancy yet are still within normal bounds—a sort of pure culture of malignant cells but still within test-tubes, as one might say. It is usually a process of very slow development; it is often relatively static and may exist for years. Ultimately the natural consequence is the break through the normal confines with an ordinary infiltrating carcinoma as the result. This probably happens more frequently from the ducts as they are so much oftener affected. On the other hand, when acini are affected break through will take place more readily owing to the slighter resistance afforded by their walls.

One may ask—why do the cells not break through at once? Reactive changes in the walls of the ducts play a part, but sometimes they are absent; and the basement membrane of an acinus would appear to be but a slight barrier. The supply of nourishment will also be concerned and it is evident that the malignant cells will be in a much more favourable condition in this respect when once they are in the tissue spaces. It is, however, clear that there may be a balance between tissue restraint and malignancy

ILLUSTRATING CHANGES IN THE MAMMA BEFORE OCCURRENCE OF CANCEROUS INFILTRATION OF THE TISSUES

FIG. 1.—Duct showing marked hyperplasia of epithelium without stroma; cells still show polarity and tendency to form circles. ( $\times 100$ .)

FIG. 2.—Localised precancerous epithelial hyperplasia in small duct; several similar foci were present. ( $\times 150$ .)

FIG. 3.—Fully developed intraduct carcinoma. ( $\times 150$ .)

FIG. 4.—Above, group of acini showing intra-acinous carcinoma; below, unaffected acini. ( $\times 75$ .)

FIG. 5.—Masses of cancer cells within interpapillary processes of epidermis of nipple—"Paget" lesion; also separate cancer cells. Secondary to intraduct carcinoma. ( $\times 150$ .)

FIG. 6.—Mass of cancer cells in deep part of epidermis, showing several mitoses (from same case as Fig. 5) ( $\times 200$ .)

for a long period. The same holds when the malignant cells reach the epidermis and produce Paget's disease.

It may seem strange, almost incredible, that intraduct carcinoma may exist for some years before infiltration occurs, but it is not so strange if one bears in mind how many years may elapse before there is recurrence after operation, that is, before cells actually infiltrating have been again able to produce a manifest growth. I shall add only one other point. From a picture of malignant cells within the mammary ducts one can readily understand how trauma may set up actual invasion.

#### STRUGGLE BETWEEN MALIGNANT CELLS AND NORMAL TISSUES

This struggle has often been observed and is of two main types. In the first place, the presence of malignant cells within ducts may give rise to reaction of the connective tissue inside the elastica. This tissue often undergoes a laminated thickening leading to diminution of the lumen, and as it progresses the cancer cells are gradually strangulated, as it were, and ultimately disappear. The condition corresponds with a chronic endarteritis proceeding to complete obliteration. This process has been described and figured also by Cappell (1931). In the second place, there may occur a marked cellular reaction around the affected ducts and also around affected acini, the cells being chiefly plasma cells and lymphocytes. At places these may penetrate the walls of the ducts and as this occurs the elastic tissue disappears. The contained cancer cells are then invaded and again they may undergo atrophy and disappear; fibrosis of the newly formed connective tissue follows. The result of either process is that obliterated ducts come to be represented by a relatively acellular core of hyaline tissue surrounded by markedly hyperplastic elastic tissue. Ducts in this condition are of common occurrence both when intraduct carcinoma alone is present and also when infiltrating carcinoma has supervened. I cannot say that ducts in this state are always the result of effete intraduct carcinoma but there is no doubt that this is often the mode of development. The same sort of cellular infiltration as that described is seen also round intra-acinous carcinoma, and it would almost appear as if the cells in the malignant state had a chemotactic influence on the lymphocytes and plasma cells. Malignant acini may be invaded by them and all stages up to complete disappearance of malignant cells may be followed. Such processes of healing are of course effective only here and there and the disease as a whole is progressive. Nevertheless they illustrate well "the conflict between malignant cells and the normal tissues."

#### THE CANCER CELL AS "PARASITE"

The parasite-like behaviour of the cancer cell is only a descriptive term without reference to the ultimate nature of malignancy. A striking example is the growth of cancer cells within non-neoplastic epithelium which is found in those rare cases where the cells of an underlying carcinoma invade the epidermis and then spread within the latter just like parasites, occurring in clumps and also as isolated cells. I show you coloured photomicrographs † from the case published by Shaw Dunn (1930). The tumour is a mucoid (colloid) carcinoma and has been stained by mucicarmine. You will see at a glance the cancer cells stained red within the epidermis, especially in the deeper layers; a great many cells are quite

isolated. Such a mode of spread is, however, commonest in connexion with intraduct carcinoma, and in my opinion it is the basis of Paget's disease of the nipple.

The distribution of the malignant change within the ducts depends in part on multiplicity of foci and partly on the manner of spread, and the latter includes the intra-epithelial route. To put the matter briefly, once the cells have assumed malignant properties they may infiltrate the lining epithelium and grow within it. The malignant cells again behave like parasites and the epithelium plays a passive rôle. The epithelial cells invaded are in fact compressed by the malignant cells though they may be recognisable for some time by their flattened and atrophied nuclei. One may see large oval malignant cells with characteristic nuclei growing in an isolated manner here and there, or they may form a continuous sheet of cells covered by a persisting layer of the original epithelium. I have traced this mode of intra-epithelial growth at all stages and in all parts of the mammary tissue. I have seen it within acini, in the small and large ducts, in the ampullæ and large ducts of the nipple. It is more frequent in the last-mentioned situation, possibly because the epithelium there has a purely lining function to the pathways and presents more resistance to the spread. I have seen isolated malignant cells confined to the epithelium at the orifices of the ducts where the cells first arrive at the epidermis. Spread then occurs in the latter, producing the Paget lesion, and the peculiar appearances of the invading cells are simply due to their growing in a comparatively resistant epithelium. Sometimes, however, the growth is of an active type (Figs. 5 and 6). I need not go further into details as I have described them elsewhere (1927, 1935); the point that I wish to emphasise is that the parasite-like behaviour of the malignant cell is brought out in a striking manner in these conditions and situations.

#### PRECANCEROUS CHANGES AND THE ENDOCRINE FACTOR

A considerable diversity of opinion still prevails as to the relation between cystic disease and carcinoma. One can approach the question from two points of view. From the clinical side one can follow up cases of cystic disease and find the incidence of carcinoma in these. The results obtained by this method are somewhat conflicting. On the other hand, one can study histologically breasts in which carcinoma has already developed and search for evidence of precancerous changes. My experience is that with the latter procedure it is the rule to find epithelial hyperplasia on the basis of which malignancy has developed. The epithelial growth is often associated with cysts but these may be of microscopic character and more frequently still would not be recognisable as such during life. Malignancy may develop in connexion with large cysts, but epithelial hyperplasia is the all-important factor, and although the two types of lesion, cysts and hyperplasia, may coexist sometimes in striking fashion, I think that they are often in inverse proportion to one another.

To interpret the above changes as the usual precursor of malignancy agrees with what we know regarding malignant disease elsewhere and especially with the results of experimental work on carcinogenesis. In the complete absence of evidence that the changes are of inflammatory nature produced by some outside agency, it was natural to regard them as in some way the result of endocrine disturbance, though it seemed more difficult to apply this

† The lecture was illustrated by lantern demonstration of photomicrographs in colour.

explanation to the numerous examples of localised hyperplastic change. Such a view is in agreement with what had been demonstrated with regard to endometrial abnormalities. I shall refer briefly to what has been established.

The effect of folliculin or œstrone on the resting mamma was first, I believe, described by Goormaghtigh and Amerlinck (1930), who demonstrated the important effect of the hormone in producing growth. Lacassagne (1932) was, however, the first to show that carcinoma may be produced by repeated administration; this has been confirmed by Burrows (1935), Bonser (1936), and Cramer and Horning (1936) in this country. Lacassagne showed that in the case of male mice of a susceptible strain the incidence of carcinoma was very high, but malignancy developed also in a proportion, though much smaller, of unselected mice. Briefly one may say that œstrone causes in the male mouse a growth of the relatively atrophic epithelium of the ducts of the mamma, this growth being often attended by dilatation and accumulation of a colloid-like secretion. The epithelium also may show hyperplastic changes and occasionally there may be a growth of small intraduct papillomata. There may be accompanying growth of acini from the extremities of the ducts and a considerable portion of glandular tissue may thus develop, this resembling what occurs in the female mamma at the time of full sexual development. These are the essential changes, and from an examination of sections kindly lent me by Dr. Lacassagne and Mr. Burrows I consider that they belong to the same category as those in the human disease. Accordingly, the male breast is in a sense changed into a female breast, and thereafter the tendency to development of carcinoma makes itself evident. Inherited susceptibility plays a very important part but the carcinogenic action is manifest, though to a less degree, in animals of ordinary strains. Here we have an example of the remarkable effect of a hormone affecting a tissue specifically related to its action. The proliferative changes followed by malignancy in a sense correspond with those produced in other tissues by carcinogenic agents, but in the present case it is to be noted that the agent is not applied directly to the tissue in question but is carried to it by the blood stream. There is thus, as I have said, a specific relationship between the œstrone or other compound and the mammary tissue.

One must however be cautious in interpreting the significance of these results. The two important points are that proliferation brought about by a growth-producing stimulus goes on to malignancy and also that the action of the agent is of a peculiarly selective kind. It does not follow from such experiments that the changes in the human breast are the result of œstrone in excess. It is known, for example, that lutein also is concerned in the mammary changes in connexion with menstruation and pregnancy, and our knowledge is at too early a stage to allow any opinion as regards the mode of production of hyperplastic cystic disease. Nevertheless the facts give strong support to the view that cystic hyperplasia is the result of disordered endocrine balance. Advancing knowledge goes to show that this balance is of a very delicate kind. It is interesting to note that Cramer and Horning have found that the repeated administration of œstrone may produce an adenomatous condition of the pituitary—another example of the interdependence of the endocrine system.

It is thus seen that malignancy may arise in different ways—it has in a sense many different initial causes—and that previous reactive or non-neoplastic

proliferation is a common and important factor. An analogy is sometimes drawn between the inflammatory process and the cancerous or malignant process. Each undoubtedly results from many diverse causes and each is incapable of ultimate explanation. But in inflammation there is a combination of cell proliferation, tissue formation, phagocytosis, &c.; the changes are directed towards the defence or repair of the tissues and are representatives of processes normally in operation. Inflammation, in fact, may be regarded in chief part as evolved for the benefit of the organism, and though, like malignancy, it often cannot be controlled, it is regulated by the presence of the irritants or micro-organisms, and on their removal or destruction it comes to an end. In malignancy, although there may be no phenomenon new in kind, the intensity and autonomous character of the proliferation, resulting usually in the death of the organism, is in certain respects a unique phenomenon. Why is the growth not controlled by the normal agencies? I shall now discuss this question.

### Essential Nature of Malignancy

With regard to the essential nature or cause of malignancy there have been many theories. Any theory must of course be applicable to all the known facts and must also stand every experimental test. With advance in knowledge views formerly held have had to be put aside and there are now two main theories. The one is that malignancy is the result of a change in the mechanism of the cell; the other is that it is produced by the presence of a virus. The first of these has been held by many, and within recent years has been brought into prominence by Boveri (1933), who described the change as a definite "abnormal chromosome-complex," or as Murray puts it, "an invisible, partial damage to individual chromosomes." It has been modified by Lockhart-Mummery (1934) in the form of gene mutation of somatic cells. I would prefer, however, to avoid the use of terms which may have a connotation not strictly applicable to malignant growths. The essence of all such theories is that the cell mechanism has undergone a change, evidently in the nucleus, which is apparently permanent and transmitted to the cell descendants. In this form the theory is little more than a summary of the facts already discussed. The change in the cells, which be it noted is in at least most instances produced by environmental conditions, appears to be twofold. In the first place there is the escape from the normal growth-controlling agencies of the body. In the second place there are the altered characters of the cells which give the tumour its special structural characters. Both of these alterations are transmitted in series and the first is manifestly of a very fundamental kind.

The parasitic theory has passed through many phases. The coming of bacteriology and the establishment of the relationship of bacteria and other micro-organisms to granulomata naturally suggested that malignant tumours were brought about in a similar way; and the idea of an extraneous agent as the cause was to many more satisfying than the hypothesis of altered cellular mechanism. Various organisms have been put forward—protozoa, bacteria, yeast, &c.—but it is now generally recognised that if a parasite is concerned it can only be an invisible micro-organism such as a virus. No definite pronouncement can be made on the subject but some established facts with regard to the virus theory may be considered.

## THE VIRUS THEORY

The discovery of Peyton Rous in 1911 that in fowls a sarcoma can be transferred by a cell-free filtrate is a fundamental one in biology and starts a new era in connexion with neoplasia. It was thus shown that malignancy can be transferred apart from the medium of living cells, the latter method having been up till that time the only one by which it could be effected. As is well known to you, the sarcoma occurred naturally in a fowl, and since that time a considerable number of filterable tumours in birds have been discovered—sarcoma, osteo-sarcoma, endothelioma, &c. Nothing is known as to the origin or initial causation of the natural growths and there is no evidence that they are passed from bird to bird like an infection; they occur sporadically. They have all the characters of malignant neoplasms, and the only peculiar feature is that they can be transferred by the agency mentioned. The filtrates of such growths are specific in the sense that they are active only in birds of the same species or in closely allied species; in this respect there is a correspondence with what obtains in the case of transplantation by living cells. The filterable agent has another characteristic feature—namely, that it reproduces in specific form in the new growth the characters of the original growth.

It is important to realise that the filterable agents in these tumours cannot be placed in the same class as the carcinogenic agents. The former produce malignant proliferation almost at once and, what is of greater significance, they are reproduced or increased in amount as the tumour grows. Carcinogenic agents have done their work when they have started malignancy; they are not present, for example, in the secondary growths. The filterable agents, on the other hand, both start and maintain the malignant proliferation and are present in the tumour tissue wherever it is. Two questions thus arise: first, what is the nature of the filterable agent, and second, to what extent can the results established with regard to these growths be applied to malignant tumours in general?

Gye (1925), from his observations, put forward the view that the filterable agent is of dual nature. There is a specific factor formed by the tumour cells—specific for the type of growth and produced in them as malignancy develops. There is also a virus which is common to malignant neoplasia in general but which for its action requires the co-operation of the specific factor. This view theoretically is in accordance with the facts stated above, but all attempts to prove definitely the dual nature of the filterable agent have so far been unsuccessful. If this is to be the ultimate result, is it possible to explain the facts on the assumption that there is a single agent? Whether is the virus or the specific factor to be retained? According to Gye's theory the specific factor produces the structural characters of the growth, but it has a further effect—it induces the cell to produce more of itself. In other words, there is an increase of the specific factor as the tumour grows, thus there is a resemblance to multiplication. There remains to be considered only the effect supposed to be due to the virus—viz., the cell proliferation induced. In view of what is known with regard to hormones and other substances, may not the specific factor, seeing that it is reproduced, be the cause also of the uncontrolled growth?

If the filterable agent is a virus the question arises—is there one or are there many? On the supposition that there is a single virus one great difficulty presents itself owing to the fact that it produces in the new tumour the features of the tumour from which it

comes. That a virus should be modified by the tissue in which it has gained a footing and grown is in accordance with what we know, but that it should, as it were, carry with it the characters of its environment in the original growth to a normal tissue is a phenomenon to which so far as I know there is no parallel. If, on the other hand, there is a multiplicity of viruses or a virus for each tumour, we are left with insuperable theoretical difficulties, which were met by Gye's view as to the dual nature. The filterable agent corresponds in many of its properties with a virus or living organism, and the majority of workers on the subject accept the virus theory. Others, however, consider that its virus nature has not been established. Murphy (1926), for example, believes that it is a cell product which he considers a transmissible mutagen; this is at least a descriptive name for Gye's specific factor. These seem to me the essential facts bearing on the subject, but I may refer to one or two other points.

What is required in this field of inquiry is some method of definitely recognising a virus. Suggestive experiments have recently been published by Ledingham and Gye (1935) with regard to this. In the case of the Rous sarcoma they have centrifuged at high speed the infective fluid and have demonstrated in the sediment elementary bodies similar to those found in vaccinia and other virus diseases. Moreover the infectivity of any portion of the fluid is in proportion to the number of such bodies. These results at once raise the question whether such bodies can be seen in other kinds of malignant growths and especially those which are produced experimentally by carcinogenic agents. Time alone will supply the answer but the result, whatever it may be, has an important bearing on the problem as to whether the fowl tumours occurring naturally and those produced artificially are alike in this respect. It may be noted too as another point of interest that intranuclear inclusion bodies resembling those seen in certain virus infections have been observed in some tumours by Dorothy Russell (1932) and others.

An all-important question is whether there is a filterable agent in an artificially produced fowl tumour, as contrasted with a naturally occurring tumour such as the Rous sarcoma. As an example, dibenzanthracene in lard or some other vehicle is injected into the breast muscle of a fowl; in a short time the dibenzanthracene is no longer demonstrable at the site (Chalmers, 1934); some months later a sarcoma develops—a remarkable series of events. Can a tumour be set up in a fresh fowl by injection of a filtrate of an emulsion of the tumour thus produced? Peacock (1935) has carried out a large number of experiments on this subject with great care and persistence, and the results have been uniformly negative; he has been able to find no evidence of a filterable agent. McIntosh (1933), on the other hand, has obtained three positive results. This is another problem to which a definite answer cannot be given; we must await further evidence. If it is found possible to transmit such artificially produced tumours by the method mentioned, this might be due again to a product of the malignant cells or to a virus secondarily invading the proliferating cells and rendering them malignant. In the latter case the question arises as to the origin of the virus and the method by which it has reached the site of inoculation, and this will be referred to below.

## VIRUSES AND MAMMALIAN TUMOURS

The general facts with regard to tumours produced by a cell-free filtrate correspond in a striking way

with those observed when transplantation of living cells is the agency. The filterable agent has been found only in some connective tissue and endothelial tumours of birds; in other instances such growths have not been filterable. So far as I know, there have been no undoubted examples of transference of a mammalian tumour by this method. This restriction in occurrence does not weigh greatly with me; it does not imply that the filterable tumours are in nature different from other growths. It is well known that a filterable tumour may lose its filterability and again regain it. The negative results in the case of epithelial growths too are not surprising since, owing to the difficulty of bringing the neoplastic agency sufficiently long in contact with the homologous epithelium, the test is an exacting one.

The domain of viruses as pathogenic agents is gradually being extended by investigation, and some definite tumours have been shown to be caused by them. A recent example is the work by Peyton Rous and Beard (1934) on Shope's infective papilloma of the cotton-tail rabbit in America. This growth is undoubtedly caused by a virus; under natural conditions it spreads as an epidemic and the lesion can be artificially propagated by scarification. Now if a portion of such a papilloma is transferred into the internal tissues or organs of rabbits, the appearance of an infiltrating epithelioma is produced. More recently they have shown that papillomas induced in domestic rabbits by the virus progress to malignancy in a considerable proportion of cases. These are interesting results; how are they to be interpreted? It can be demonstrated that the virus is present in the epithelioma since a papilloma results when the skin of a normal rabbit is inoculated from such an epithelioma. The problem here comes to be quite a definite one—does the malignancy of the epithelioma, that is the uncontrolled proliferation of its cells, depend upon the presence of the virus or has the virus produced malignancy as other carcinogenic agencies may do, the virus then merely persisting in the malignant growth? In other words, if the virus could in some way be removed from the epithelioma, would malignancy persist or would it come to an end? Till this is answered it is not possible to assess the general bearing of the observations.

I have given briefly the chief facts relating to the subject and it is not possible to give definite answers to the question put above with regard to the nature of the filterable agents in fowl tumours and their relation to other growths. Certain fundamental facts have been established and one would like to be able to bring them into harmony with our knowledge of malignant tumours in general and give a comprehensive view, even if it were merely theoretical. At present this does not seem possible. But if we consider as a whole the results with regard to carcinogenesis and the filterable growths, there is no valid evidence that malignancy in general is produced by a virus or viruses entering the body *from outside*. The experimental facts appear to exclude this possibility. This is a matter of great practical as well as theoretical importance. Malignant growths can be set up by carcinogenic agents so regularly, not only when they are applied externally but when they are introduced into the tissues, that the access of a virus from without on each occasion seems impossible. The high percentage of growths produced in cancer-susceptible strains of mice by means of cetrone is a specially significant fact in this connexion. Even if it were supposed that a virus were a practically ubiquitous commensal on the skin and mucous surfaces, this would not explain the regularity with

which growths may be produced in the deeper tissues. It may be that some human malignant tumours are due to viruses entering the body from outside, but this does not affect the general question.

The matter has been investigated too from the experimental side. Rous and Botsford (1932) reared mice from birth in a sheltered condition—that is, they were protected against the entrance of any infective agent from without, though the growth of commensal bacteria such as coliform organisms or cocci was not prevented. It was found that in such mice repeated applications of tar led to the development of epithelioma just as readily as in normal mice. We thus seem to be driven to the conclusion that if a virus is necessary for malignancy it must be present within the normal tissues in the interior of the body and act only when proliferation has been previously set up by carcinogenic agents or in some other way. Various supporters of the virus theory have been forced to this view; it has recently been expounded by Andrewes (1934) and the facts bearing on it have been marshalled by him. It is a hypothesis on which nothing definite can be said. No one can prove or disprove the presence of a virus in normal tissues ready to produce malignancy when occasion offers. It must be noted however, as has been already mentioned, that in addition to uncontrolled proliferation there are alterations in the characters of cells which are transmitted to their descendants. The experimental work on cancer in the mouse shows clearly that the cells of a malignant growth breed true both as regards their characters and rate of growth. As Murray (1933) puts it, the growths show "a continuous graduated series in those arising from any one tissue both in histological structure and in rate and habit of growth. In spite of this great range any one variety is relatively permanent." Can this impress resulting in special features be made by a single virus? No one doubts that such an agent as cetrone of itself produces the hyperplastic changes in the mamma, varying greatly in different cases, and a virus, if one there be, can come into play and produce uncontrolled proliferation only when these essential changes have occurred. It seems to me that transmission of permanently altered cell characters must also be a necessary factor. The same applies to growths in the human subject. The numerous and practically endless variety of histological types must be due to forms of proliferation and hyperplasia brought about by the various agencies referred to, aided of course by congenital abnormalities and inherited susceptibility.

#### IGNORANCE AND KNOWLEDGE

Each of the two theories has its strong supporters but a decision is not to be arrived at by the votes even of so-called authorities. On either view there seems to be a failure on the part of nature. In the one case normal proliferative processes evolved for defence and repair—one may say, "for the good of the organism"—pass into malignancy. In the other case the animal body has somehow come to harbour a virus or viruses which, given certain opportunities, lead to its destruction. It may seem that for practical purposes it is immaterial which of these two hypotheses is correct; nevertheless, the demand for intellectual satisfaction is and always will be insistent. The problem seems to be in a realm which we have not yet the means of entering, and some think it is incapable of solution. But no one conversant with the advances in recent times can doubt that at least fresh light will be thrown on the subject.

In what I have said a sharp distinction has been

made between the conditions which induce malignancy and the real nature of malignancy or, as one may say, the essential cause of the uncontrolled proliferation. If we are held up for the present by our ignorance of the latter the advances in our knowledge of the former have brought results which have an important practical bearing. I remember some thirty years ago hearing an authority on tumour growths discuss the question whether neoplasia could arise in tissues previously normal. We have now moved far from such a standpoint. The advances in knowledge during that period have been numerous and substantial and in the main due to the experimental method. There have been three main phases of experimental investigation—first, the transference of naturally occurring malignant growths by transplantation of their cells into normal animals, and the conditions and limitations of such transference; second, the methods of starting malignancy *de novo*; and third, the transference of tumours by means of a filterable agent. In all three departments much has been accomplished.

The fact that the problem as to the essential nature of malignancy has not been solved has unjustifiably obscured what has actually been achieved. That malignancy may supervene on cellular proliferation brought about in various ways, by irritants, cell stimuli and hormones, and as a result of compensatory hyperplasia; that in most cases a long period elapses between the onset of proliferation and malignancy; that in the case of chemical substances the tendency to institute malignancy is in certain instances related to molecular structure; that inherited susceptibility plays an important part especially in certain organs; that the development of malignancy depends in some cases upon congenital abnormalities, and that these factors may be combined in different ways—these are facts which have been completely established.

Knowledge of causes brings with it the possible means of prevention and has already been effective. Recognition of the necessity for an intimate study of growths, simple and malignant, in every organ and region of the body is clearly shown by the publications of the present time. And in investigating what I may call the natural history of neoplasia close coöperation between clinical observers and pathologists is essential for the attainment of the best results.

I see much that is hopeful. In the various departments of inquiry to which I have made reference fresh stimulus has been supplied by recent advances. It is natural, in fact it is right, that workers in any one field should push the implication of their results to the full, but all results must be coördinated and tested in relation to the fundamental questions. The picture I have endeavoured to present has come chiefly from researches in the last twenty-five years. I have little doubt that in another similar period it will be greatly changed and that what I have brought before you in this address will be only a record of what has been.

## VITAMINS IN HUMAN NUTRITION THE EXCRETION OF VITAMIN B<sub>1</sub> IN HUMAN URINE AND ITS DEPENDENCE ON THE DIETARY INTAKE

By LESLIE J. HARRIS, Sc.D., D.Sc.

MEMBER OF THE SCIENTIFIC STAFF, MEDICAL RESEARCH COUNCIL; AND

P. C. LEONG

TRAVELLING STUDENT, RAFFLES COLLEGE, SINGAPORE

(From the Nutritional Laboratory, Medical Research Council and University of Cambridge)

IN the past the assessment of malnutrition, or of "suboptimum-nutrition," has been based largely on measurements of physique; various alternative formulae have been proposed by which numerical expression may be given to the weight-height or weight-age relationships. The clinical appearance, and to a less extent the physical performance,<sup>1</sup> are two other criteria most commonly used. To-day, however, the realisation is growing that more specific tests should be available to establish the presence of any given type of dietary deficiency. Not only is it important when a child is undernourished to know which specific dietary errors are responsible, but—more important—it has to be realised that partial deprivation of an essential factor may not lead to any obvious symptoms of ill-health at all for some considerable time to come. In the latter case then a specific test for a given vitamin or other nutritive element may give the first evidence that nutrition is in fact suboptimal.

For vitamin C it has already been shown that the amount excreted in the urine<sup>2,3</sup> may serve as the basis for a test. Subjects suffering from avitaminosis C cease to excrete vitamin C in their urine and in contrast with normal subjects fail to give a urinary peak of response after the administration of a suitable test dose. Quantitative data for the excretion and response to test doses have now been determined for subjects given the reputed "minimal" or "optimal" doses of vitamin C.<sup>3</sup> With the object of

elaborating similar methods for vitamin B<sub>1</sub> the experiments to be recorded below were undertaken.\*

*Past work.*—Very little information of a quantitative nature is available in the past literature as to the amount of vitamin B<sub>1</sub> in urine. Muckenfuss<sup>4</sup> in 1918 concluded from feeding tests on pigeons that "the antineuritic vitamin . . . is present in fresh filtered human urine in traces apparently." Although similar experimental results were obtained by Gaglio<sup>5</sup> in 1919, he, on the other hand, supposed that this action upon the pigeons was due to some non-specific substances and not the vitamin itself. In view of this uncertainty van der Walle<sup>6</sup> reinvestigated the question in 1922 and concluded from pigeon feeding tests that "a small quantity of antineuritic vitamin is present in the [human] urine." When he fed a dog on a vitamin-free diet the urine lost its curative power. More recently, a preliminary note by Helmer<sup>7</sup> states that the presence of vitamin B<sub>1</sub> in human urine can be detected by a growth-test on rats; he fed the evaporated equivalent of one twenty-fifth part of the total daily output of urine and an appreciable growth response was seen.

**Technique**

It early became apparent that some method of concentrating the vitamin B<sub>1</sub> from the urine was necessary before it could be tested satisfactorily on the experimental animal. After a trial of various alternatives, we found that the following very easy procedure sufficed—namely, to shake the urine with "acid clay" in order to adsorb the vitamin, and then feed the activated solid direct.

TABLE I  
*Quantitative Control of Method. Adsorption of Added Vitamin B<sub>1</sub> from Urine*

Amount of crystalline vitamin B <sub>1</sub> HCl added, in γ, to 100 c.cm. of vitamin B <sub>1</sub> -free urine.	Amount found adsorbed, γ.	Percentage recovery.
2 .. ..	1.9	95
5 .. ..	3.7	74
5 .. ..	3.7	74
5 .. ..	5	100
10 .. ..	7.5	75
10 .. ..	9.3	93

Control tests (Table I.) show that with this method under suitable conditions the great bulk of the vitamin B<sub>1</sub> is removed by two such successive adsorptions. Specimens of 100 c.cm. of urine were first autoclaved at pH 10 for 4 hours under 2 atmospheres pressure, in order to destroy the vitamin B<sub>1</sub>. To the autoclaved urine various known amounts of crystalline vitamin B<sub>1</sub> hydrochloride were then added. The reaction was adjusted to pH 5, and two successive adsorptions carried out by the addition of two lots of 1 g. of acid clay. The two specimens of activated clay were then combined and fed to rats in the manner described below.

Other adsorbents were tested under similar conditions (pH 5, 20° C.) as possible substitutes for "acid clay," but were found less effective (Table II.). Further control tests showed that the adsorption was best carried out in the region of pH 5 (Table III.).

*Details of technique.*—The full 24 hours' specimen of urine should be collected, preferably under a few cubic centimetres of toluene added as preservative. The total day's volume is noted, and the reaction is adjusted to about pH 5 (brom-cresol-green may be used as indicator) by the addition of a few drops of HCl as necessary. An aliquot part of the urine is taken for estimation (normally 100 to 200 c.cm.,

\* The methods available for other nutritional factors will be discussed in a separate note (Harris) to be published shortly in THE LANCET.

depending whether the total daily volume is low or high; or 50 c.cm. if the diet is rich in vitamin B<sub>1</sub>, as after a test dose). One gramme of Clarit acid clay (obtained through the kindness of Messrs. Lever

Brothers Ltd., Port Sunlight) is added. The mixture is shaken on an automatic shaker for 15 minutes and filtered. The filtrate is treated with a further 1 gramme as before, shaken and filtered again. The two specimens of activated clay are combined and tested direct on the rat, mixed in with a small fraction of his basal diet.

TABLE IV  
*Effect of Storage on Vitamin B<sub>1</sub> in Urine*

	Amount of vitamin B <sub>1</sub> found, I.U. per 100 c.cm.		
	Sample—		
	1	2	3
Fresh urine .. ..	0.5	2.4	1.9
After 48 hours' standing—			
No preservative .. ..	—	1.9	1.4
With chloroform .. ..	0.5	2.6	—
With toluene .. ..	0.5	2.4	—

As will be seen from Table IV. the presence of toluene is sufficient to preserve the vitamin from destruction, for several days at least. Further, the activated acid clay if dried retains its full activity even after 3 months' storage in a refrigerator (Table V.). This finding is of interest as it suggests the possibility of having assays on the patient's urine carried out at a distance whenever there are no local facilities for the animal test—e.g., in the East where beriberi is prevalent. Such work is at present in progress (see below).

*Animal test.*—Because of its rapidity, convenience, and accuracy the "bradycardia" method (Harris)<sup>8-10</sup> seems most suitable. The irregularities and "scatter" inherent in the pigeon method are obviated, and in contrast with the rat-growth method only a single dose of supplement has to be administered, and results can be obtained in the course of a few days instead of several weeks (i.e., the rats being available, ready prepared at the time of the test). Another

advantage is that the same rat can be used repeatedly for separate tests. The error of the method is no more than about 15-20 per cent., which compares very favourably with most biological methods.

82 ,, .. .. .	1.0	—	—

Young rats weighing about 50-60 grammes at time of test are used, having been placed on the standard vitamin-B<sub>1</sub> free diet when about 45-50 g. As soon as their heart-rate, as measured in the electro-cardiograph (Clifton Instruments Ltd., Clifton, Bristol),† has fallen from the initial value of about 500 to about 370-390 they are ready for test. Single-graded doses of "unknown" are administered to groups of such rats (for greatest accuracy, 4 or 5 animals should be included per group) and the heart-rate is measured about twice daily. The time which elapses before the heart has fallen back to the original value at the beginning of the test is noted. Simultaneously graded doses of the international standard are administered to a comparable group of rats and measurements taken in the same manner. (For the sake of accurate standardisation, similar tests have also been made with specimens of pure crystalline vitamin-B<sub>1</sub> hydrochloride obtained from Messrs. Merck; the relation found was—

$$10\gamma \text{ vitamin-B}_1 \text{ HCl} = 38 \text{ mg. of international standard} \\ (= 3.8 \text{ I.U.})$$

Average, or better median, values for each group are then calculated (see Table VI.). A dose-response

(a) = administered orally. (b) = injected subcutaneously.

curve may thus be drawn (Fig. 1), and the dose of the unknown equal in its effect to a given number of units of international standard is thus determined—or the equivalent in terms of so many γ of pure vitamin-B<sub>1</sub> hydrochloride may be given. In approximate routine determinations such lavish use of

animals is not called for; 2 or 3 tests per specimen suffices. For fuller details of technique the paper by Birch and Harris<sup>9</sup> may be consulted.

Results

EXCRETION OF VITAMIN B<sub>1</sub> BY NORMAL ADULTS

Typical results for the day-to-day excretion of vitamin B<sub>1</sub> in the urine are shown in Fig. 2 and the averages are summarised in Tables VII. and VIII.

			51	—	199
			82	—	142

\* Previous test doses had been given shortly before.

It will be seen that the subjects have been arranged in three groups roughly classified as "moderate," "normal," and "good." Nos. 1, 2, 3, and 4 (Group 1, Table VII.) are the "moderate" (or poor) group. Their dietary histories indicate a somewhat low intake of vitamin B<sub>1</sub> (the chief source being generally one egg daily and a small amount of milk), and their urinary output is likewise a little below the "normal" (average = 14 international units daily). Subjects Nos. 5, 6, and 7 (Group 2) may be classed as "average" or "normal." Their dietaries include more liberal amounts of milk, brown bread, eggs, &c.; and their average excretion is appreciably higher, about 21 I.U. daily. Two other subjects who had received a diet unusually rich in vitamin B<sub>1</sub> (Nos. 8

† The use of a simpler oscillograph may furnish a less expensive alternative.

and 9, Group 3)—namely, a special daily supplement of 16 g. of Bemax for one year past, plus a good mixed diet, including porridge, bacon, eggs, milk—may be classed as “good”; their average daily excretion was significantly higher again (31 I.U. per day).

It may be concluded, therefore, that an average normal value for the excretion of vitamin B<sub>1</sub> by adult subjects on normal diets in this country is of the order of 20 I.U. per day. The preliminary indications that the output varies according to the dietary intake is confirmed below in a series of carefully controlled observations. We may suppose that the daily excretion varies with the body’s “reserves” of the vitamin which in turn depend on the amount provided in the food. Animal tests bear this out. The amount of vitamin B<sub>1</sub> which can be held in store in the body is, however, less important than, for example, in the case of vitamin A, immense reserves of which may be accumulated in the liver.

EFFECT OF TEST DOSE

Following the technique described for the determination of vitamin-C subnutrition, we have investigated the effect of the administration of a single large test dose of vitamin B<sub>1</sub>. As with vitamin C, we have found that with vitamin B<sub>1</sub> also the effect of the test dose is related to the past dietary history,

FIG. 1.—Dose-effect curve, for pure crystalline vitamin B<sub>1</sub>-hydrochloride and for international standard preparation.

and hence to the “resting level” of excretion. That is to say, subjects having larger “reserves” of the vitamin and excreting more of it in their day-to-day “resting level” show a somewhat larger immediate response to a given test dose than do those whose past diet has been poorer in the vitamin. Typical values are given in Table VIII.

Reference to Table VIII. suggests that for the diagnosis of the more moderate degrees of vitamin-B<sub>1</sub> subnutrition a suitable level for the test dose is probably about 900γ of vitamin B<sub>1</sub> HCl (=340 I.U.). Such a dose gives a good response with “normal” subjects, and little response from subjects with somewhat subnormal past intakes of the vitamin. On the other hand, the test for subjects with unusually high values for their resting level was

FIG. 2.—Day-to-day excretion of vitamin B<sub>1</sub> by nine adults.

Group I. (Nos. 1-4).—Average resting level = 14 I.U. daily, “moderate reserves.”  
 “ II. (Nos. 5-7).— “ “ “ “ = 21 “ “ “ “ “normal reserves.”  
 “ III. (Nos. 8-9).— “ “ “ “ = 31 “ “ “ “ “good reserves.”

made more dramatically evident when a still larger test dose was tried. For example, subjects who had had a diet unusually rich in vitamin B<sub>1</sub> and were excreting it at the high rate of 51-82 I.U. per day, gave a response of no less than 140-200 I.U. after a test dose of 950 I.U.

FIG. 3.—Effect of diet free from vitamin B<sub>1</sub> on a subject with good reserves. At A a diet containing about 490 I.U. daily was given. At B a test dose of vitamin B<sub>1</sub> (342 I.U.) was given, followed by normal diet.

(Fig. 3) illustrates [the rapid depletion of reserves which occurs when a diet is taken containing no vitamin B<sub>1</sub>.

A normal subject with a good dietary history was placed for 3 days on a B<sub>1</sub>-free diet, consisting mainly of polished rice, cream crackers, egg-white, and butter. His excretion of vitamin B<sub>1</sub> quickly fell from an initial value of 51 I.U. per day to the subnormal value of 10 I.U. On the fourth day foodstuffs rich in vitamin B<sub>1</sub> were restored to his dietary (eggs, milk, pork, bacon, green vegetables; calculated to contain a total of about 490 I.U. of vitamin B<sub>1</sub>), yet his output remained for a time subnormal. This clearly indicated that a considerable depletion of the vitamin-B<sub>1</sub> reserves had occurred and that the vitamin B<sub>1</sub> consumed on the fourth day was utilised in "saturating" the tissues once again to their previous level. On the following day the excretion had returned to the original normal value. A few days later the experiment was repeated and a similar result obtained. After three days on the B<sub>1</sub>-deficient diet the test dose of 342 I.U. gave only about one half of the response obtained with a normal subject.

(2) Expt. II. (Fig. 4) illustrates results obtained with a subject having an initial low "resting level," his previous

dietary history indicating a less than average intake of vitamin B<sub>1</sub>. As the amount of vitamin B<sub>1</sub> administered daily was increased from time to time there was a corresponding slow increase in the output. Perhaps the most interesting feature of the results however was that there was some lag in the increased urinary output following upon the increased intake. This would indicate that when the vitamin-B<sub>1</sub> reserves are originally low some of the extra vitamin B<sub>1</sub> administered is first absorbed to "saturate" the tissues up to the new level.

(3) Experiments with a normal subject having a higher initial "resting level" are shown in Fig. 5. The results indicate that with a normal adult having good vitamin-B<sub>1</sub> reserves, the tissues become more rapidly "saturated" after a test dose and a more prompt response is seen in the urinary rise.

(4) A further experiment giving quantitative data for the excretion of vitamin B<sub>1</sub> by a normal subject given in turn various levels of vitamin-B<sub>1</sub> intake are recorded in Fig. 6.

QUANTITATIVE RELATION BETWEEN DIETARY INTAKE AND URINARY OUTPUT ("RESTING LEVEL")

Our results indicate that under normal circumstances only a relatively small amount of the vitamin B<sub>1</sub> taken in the food is excreted in the urine. The proportion excreted is notably less than that for vitamin C, under comparable conditions.<sup>2 3</sup>

An attempt to show quantitatively the relation between the vitamin intake and the output is made in Table IX. For this purpose we have made an allowance of 250 I.U. per day to represent the amount of vitamin B<sub>1</sub> found in the ordinary middle-class dietary. This figure was arrived at from calculations based on the vitamin-B<sub>1</sub> values of foodstuffs as determined by the "bradycardia" method and recently published by Baker and Wright.<sup>10</sup> According to our calculations (cf. below, Table XII.) the vitamin-

FIG. 4.—Effect of increase in intake of vitamin B<sub>1</sub> in subject with initially rather low reserves.

1000 .. ..	250	1250	68 (6)	5

\* Based on observations for number of days shown in parentheses.

B<sub>1</sub> values of normal dietaries vary from a value of about 200 I.U. for a better working-class regimen (in which the day's food contains moderate allowances of meat, egg, potatoes, and vegetables plus half a pint of milk) to a value of about 400 to 500 I.U. for a richer menu (containing larger allowances of eggs, bacon, potatoes, vegetables, plus one pint of milk). Such an allowance (250 I.U. per day) is clearly no more than a first approximation only, but it serves our present purpose sufficiently well.

Our results are plotted in Fig. 7 and it will be seen that there is a well-defined proportionality between the daily intake and the output of vitamin B<sub>1</sub>.

FIG. 5.—Effect of variations in vitamin-B<sub>1</sub> intake. Normal subject.

FIG. 6.—Variations in vitamin-B<sub>1</sub> excretion with intake. At C a test dose of 950 I.U. was given.

when a steady state has been reached.† The amount of vitamin B<sub>1</sub> excreted remains fairly constant at around 5 to 8 per cent. of the intake, notwithstanding the wide variations of the latter. As already hinted, this behaviour is rather in contrast with that noted for vitamin C. With vitamin C any very large increase in the intake causes a rapid

FIG. 7.—Excretion of vitamin B<sub>1</sub> with varying intakes. (Crosses represent averages of groups.)

rise in the output; the tissues quickly become "saturated"; and before long the greater part of the extra vitamin ingested will be excreted—instead of generally only about 5 to 8 per cent. of it as with vitamin B<sub>1</sub>.

† It is important to realise that in this section we are referring to the steady state of excretion after equilibrium has been attained on a given fixed daily dose of the vitamin continued for some time—i.e., when "saturation" has been reached for the given level of intake. Obviously the more immediate response seen just after a change has been brought about in the vitamin intake—as when a test dose is given—depends on the past vitamin history, that is, on the state of the body's reserves.

It is reasonable to assume that vitamin B<sub>1</sub>, being water-soluble, is readily absorbed and distributed by the blood stream, and it appears to be quickly eliminated by the kidneys. Thus we found in one experiment that the administration to a normal subject of a test dose of 950 I.U. led to the excretion of about 90 I.U. after 2 hours—that is, about 9 per cent. of the dose given.

We may therefore conclude that in the metabolism of vitamin B<sub>1</sub> by the normal human body, about 5 to 8 per cent. of the vitamin is quickly eliminated unchanged by the kidneys, and that (apart from any lost in the faeces) a greater part of the remainder is presumably destroyed by metabolic changes in the tissues, the exact mechanism of the latter being still obscure.†

\* All subjects except these two were working-class children. The higher daily totals shown by these two compared with other children of the same age is probably significant; they are the children of a nutritional research-worker and had received a diet containing more than the usual working-class allowance of vitamin B<sub>1</sub>—including brown bread, Marmite, and ample milk.

LOW VITAMIN-B<sub>1</sub> RESERVES IN DISEASE OR ON SPECIAL DIETS

As a result of a survey of hospital patients which has been begun, a number of cases of low vitamin-B<sub>1</sub>

† Apparently little of the vitamin B<sub>1</sub> of the food is lost in the faeces. The antineuritic potency of the latter is due to the presence of micro-organisms and bears little or no direct relation to the amount of vitamin B<sub>1</sub> in the diet (unpublished data).

excretion has come to our notice. Three examples may be cited here.

CASE 1.—Aged 72, suffering from carcinoma of the œsophagus, could eat little solid food, and at the time of examination had been on a "light hospital diet" for three days containing little vitamin B<sub>1</sub>. His daily excretion of vitamin B<sub>1</sub> was only 4 I.U. per day.

CASE 2.—Aged 41, suffering from general malnutrition, had a daily output of only 2 I.U. He was examined four and five days after admission during which time he had been on "normal hospital diet."

CASE 3.—Aged 60, suffering from bronchiectasis, and on a "normal hospital diet" for four days excreted only 7 I.U. daily (av.).

It is possible that in certain diseased conditions the absorption of vitamin B<sub>1</sub> from the food is interfered with. Further experiments are also in progress to determine how far lower reserves of vitamin B<sub>1</sub> are common in old age.

DATA FOR CHILDREN

Analyses for vitamin B<sub>1</sub> have been carried out on the urine from a number of infants and children. The results so far obtained indicate that the average values for the concentration of the vitamin in the urine is similar to that for adults—viz., about 1 to 2 I.U. per 100 c.cm. The average total daily outputs, calculated on the basis of kilogramme body-weight, is also of the same order as for adults or perhaps rather higher for the better nourished children. (See Table X.)

EXPERIMENTS WITH LABORATORY ANIMALS

As the more extreme degrees of vitamin-B<sub>1</sub> deprivation can rarely be seen in this country, and such deficiency as does exist is probably nothing more than a moderate degree of hypovitaminosis (see below), we thought it would be instructive to determine the effects upon rats not only of partial deficiencies but also of a more established condition of avitaminosis.

Our tests have led to the important finding that in vitamin-B<sub>1</sub> deficiency in the rat the amount of vitamin B<sub>1</sub> excreted in the urine becomes negligibly

Note.—Rats 5 and 6 were suffering from a more advanced state of deficiency, and rat 4 from a gradually increasing degree of hypovitaminosis.

small and indeed is scarcely possible of detection (Table XI., rats 4-6).

Furthermore, the experiments on rats confirm the two principal conclusions reached in the tests on human beings: (1) The vitamin-B<sub>1</sub> output varies according to the amount given in the diet (Table XI., rats 1-4). (2) The amount excreted is a small fraction only of that ingested—namely, about 8 per cent., when the steady state has been reached (that is the same fraction as for human beings). (Rat 1, Table XI.)

**Discussion**

Having shown that the subject's dietary history determines his excretion of vitamin B<sub>1</sub>, as also his response to a test dose, the next thing to consider is how these results may be turned to use in relation to problems of human dietetics, as for the determination of the prevalence of undernutrition and for the establishment of vitamin-B<sub>1</sub> standards. Surveys are at present in progress in which our object is to determine average values for excretion in different sections of the community, and to correlate these with the consumption of diets believed to contain either adequate or inadequate amounts of vitamin B<sub>1</sub>. A considerable amount of large-scale experimental work, carried out mainly in America,<sup>11</sup> goes to suggest that a suboptimal intake of vitamin B<sub>1</sub> is not uncommon, especially in bottle-fed babies, for when extra sources of the vitamin (generally of cereal origin) were added to the diet the growth-rates and weight curves went far ahead of those of the control groups. An immediate need therefore is

state of advanced deficiency of the vitamin (i.e., in beri-beri) vitamin B<sub>1</sub> will cease to be excreted in any significant amount. Indeed, preliminary observations (made possible by the kind help of Prof. J. L. Rose-dale) showed that in 7 cases of beri-beri no appreciable amount of vitamin B<sub>1</sub> was being excreted in the urine (viz., < 2.5 I.U. per day), although the patients had

already been placed for treatment on B<sub>1</sub>-rich diets. The urine test therefore promises to be of diagnostic use in this connexion, and we hope to publish further data on this aspect of the problem in a later communication. As a simple alternative to the test-dose technique, measurements may be made of the amount of vitamin B<sub>1</sub> excreted during a period of 24 hours while the subject is temporarily restricted to an experimental diet containing no vitamin B<sub>1</sub>. Well-nourished controls are found to carry sufficient "reserves" of the vitamin to be able to continued to excrete significant amounts of it in their urine under these circumstances (see Fig. 3).

*Nutritional standards for vitamin B<sub>1</sub>.*—It is perhaps not premature to essay a few preliminary calculations in the endeavour to determine the probable minimum (or optimum) needs for vitamin B<sub>1</sub>, and the corresponding values for the urinary response. We have estimated the vitamin-B<sub>1</sub> content of a series of characteristic normal diets, and find that an average middle-class (or a better working-class) diet at Cambridge may be expected to contain about 250 to 500 I.U. per day (see Table XII.). A consideration of past clinical records suggests that diets containing less than about 150 to 200 I.U. per day may be inadequate to cure or prevent beri-beri (Table XIII.). Hence a daily intake of 200 I.U. (for a man of 10 st.) may be fixed provisionally as the minimal standard allowance; and reference to the previous tables given in this paper entitles one to reach the conclusion that if a subject excretes less than about 12 I.U. per day (per 10 st. body-weight—the urine having an average concentration of less than about 1 I.U. per 100 c.cm.) a strong presumption must be raised that his diet contained less than a normal allowance of vitamin B<sub>1</sub>.

that such observations be correlated with the corresponding values for urinary excretion of vitamin B<sub>1</sub> on the different diets. It may be added that as far as adults are concerned there is also reason to suppose that large numbers of unemployed and poorer-paid workers, subsisting on diets consisting largely of white bread, margarine, jam, tea, sugar, condensed milk, potatoes, &c.,<sup>12</sup> are likely to be below the optimum in their intake of vitamin B<sub>1</sub>.

Judging from our own short-time experiments on B<sub>1</sub>-free diets, as well as from the experiments on avitaminous rats, there seems little doubt that in a

§ To avoid undue complication, we may ignore the consideration that more precisely the vitamin-B<sub>1</sub> requirements somewhat increase with an enlarged caloric intake or extra carbohydrate.

### Summary

In the search to find a simple method of estimating the state of vitamin-B<sub>1</sub> nutrition of human subjects, quantitative studies have been carried out of the day-to-day excretion of vitamin B<sub>1</sub> in the urine. This can be measured simply and rapidly by means of the "bradycardia" method (Harris). It is shown that the output varies with the dietary intake. In a group of 9 healthy adults (aged 17 to 37) on "normal" diets the amount excreted (November to February) was of the order of 12-35 I.U. (= 30-90  $\gamma$  of vitamin B<sub>1</sub> hydrochloride) with an average of 20 I.U. per day. This represents only a very small proportion (about 5-8 per cent.) of the daily intake of the vitamin (cf. vitamin C). The consumption of a diet containing comparatively small amounts of vitamin B<sub>1</sub> led to a proportional reduction in the daily output of the vitamin, while a diet containing large amounts produced a corresponding increase. The immediate response in excretion after a large test dose of the vitamin was also appreciable graded, according to the past dietary history. Similar results were obtained with experimental animals (rats): in hypovitaminosis-B<sub>1</sub> the amount excreted became negligibly small. Reference is made to preliminary surveys which are in progress to measure the state of vitamin-B<sub>1</sub> nutrition in groups of healthy and diseased children and adults. A daily excretion of less than 12 I.U. (corresponding with an average concentration of 1 I.U. per 100 c.cm.) raises the presumption that the diet contains less than a normal allowance of vitamin B<sub>1</sub>. Preliminary observations confirm the expectation that in actually developed avitaminosis (beri-beri) in man vitamin B<sub>1</sub> may cease to be excreted in the urine in appreciable amounts (< 2.5 I.U. daily).

Our thanks are due to Dr. A. Z. Baker, of Vitamins Ltd., for supplying concentrated preparations of vitamin B<sub>1</sub> and specimens from two human subjects on special diets. Estimations on several pathological subjects were made possible through the valued collaboration of Dr. Leslie Cole and Dr. John Yudkin at Addenbrooke's Hospital, Cambridge.

DEACONESS HOSPITAL, EDINBURGH.—At the annual general meeting of the Church of Scotland Deaconess Hospital reference was made to the extension and reconstruction of the hospital which is now being carried out. The total alterations involve an expenditure of £40,000, of which £28,000 has already been subscribed. The hospital has been closed since August, 1935, but the district maternity work has been continued. It is hoped that the reconstructed hospital will be reopened in October.

## GLYCOSURIA AND ACETONURIA IN SUBARACHNOID HÆMORRHAGE

A REPORT OF FOUR CASES

By E. J. S. WOOLLEY, M.B., M.R.C.P. Lond.

LATE MEDICAL REGISTRAR, ST. GEORGE'S HOSPITAL, LONDON

THE occurrence of hyperglycæmia and glycosuria following cerebral injury has been recognised since Claude Bernard described his experiments of fourth-ventricle puncture in the middle of the last century. As one of the findings in the examination of the urine of patients suffering from hæmorrhage into the subarachnoid space glycosuria is by no means uncommon. When this glycosuria is associated with acetonuria in a comatose patient, it may lead to errors of diagnosis. This possibility has been pointed out by Hinds Howell,<sup>1</sup> but apart from his observation it seems that the condition has attracted little attention in this country. In 1929 Römcke and Ustvedt<sup>2</sup> described 27 cases of subarachnoid hæmorrhage: in one of these glycosuria and acetonuria were found. In the following year 2 more cases were described, 1 by Bix<sup>3</sup> in Vienna and 1 by Vitkova and Vitek<sup>4</sup> in Paris. Römcke and Skouge<sup>5</sup> have since described 14 cases of cerebral hæmorrhage and 1 of epilepsy in which acetonuria was demonstrated. More recently 2 further cases have been recorded by Jamieson and Scott<sup>6</sup> in Canada, and 1 by Rathery, Hesse, and Roy<sup>7</sup> in France.

In each of the 4 cases of hæmorrhage into the subarachnoid space described below, acetone and sugar were found in the urine, and 1 presented a clinical picture which resembled in some respects that of hyperglycæmic coma. An examination of the records of St. George's Hospital has revealed 1 other case of proved subarachnoid hæmorrhage in which it is recorded that "a minute trace of acetone" was found in the urine. Since the nature of the test used and the extent of the minute trace of acetone demonstrated are not disclosed, the case is not included in this series. It is of interest, however, to note that this patient was given insulin before the true diagnosis was revealed by lumbar puncture.

### CASE RECORDS

CASE 1.—A woman, aged 59, was admitted to St. George's Hospital Dec. 24th, 1933. It was stated that she had suffered from "blood pressure" for some months, but the exact nature of her symptoms was never satisfactorily ascertained. No story could be obtained from relatives in any way suggestive of the symptoms of diabetes mellitus. It was subsequently learnt that her systolic blood pressure had recently been in the neighbourhood of 240 and that the urine was sugar-free a few weeks before admission. On the evening before admission she took a short walk, and on her return sat down in a chair to rest. Here she was discovered by her relatives, who found that they were unable to rouse her. She remained unconscious throughout the night, vomiting from time to time. At 11.30 on the following morning she was admitted to hospital.

On examination she was profoundly unconscious; the temperature was 99.4° F.; pulse-rate 130, regular and of good volume; respiration-rate, 36; blood pressure was 130/80. The breath was excessively foul but free from any odour of acetone; the intra-ocular tension was not abnormal; the tongue was dry and coated, and crusts hung from the lips. The heart was slightly enlarged, the apex-beat being in the fifth space 4 inches from the mid-line; the sounds were weak and there were no murmurs. Apart from moist râles at both bases the chest was normal. The pupils were slightly dilated and failed to react to light; there was no corneal reflex; the fundal vessels showed some arterio-sclerotic change and the discs were

normal. All tendon reflexes were extremely sluggish and the abdominal and plantar reflexes were not obtained. The urine contained red cells, albumin, sugar by Fehling's and Benedict's tests, and acetone by Rothera's nitroprusside test; the last-named test was strongly positive, but Gerhardt's ferric chloride test was negative. The cerebro-spinal fluid was under a pressure of 230 mm. of fluid and two specimens which were withdrawn consecutively were intimately and equally mixed with blood.

*Course.*—The patient failed to regain consciousness and died of pulmonary œdema 48 hours after admission. Permission to make a post-mortem examination was refused.

**CASE 2.**—A woman, aged 29, a domestic servant, was admitted to the hospital Sept. 29th, 1935. For about two years she had suffered from headaches which had become gradually more severe during the last few months; otherwise she had enjoyed good health. There was no history of polyuria, polydipsia, or loss of weight. At 11 o'clock on the night of her admission, while visiting her mother, it is stated that she complained of pain in the back of the neck and said that she felt unwell. She returned to her place of employment and retired to bed. At midnight she rang her bell and was found in a dazed condition from which she rapidly passed to deep coma. There was no history of her having vomited.

*On examination* at 2.30 A.M. she was found to be deeply unconscious, cold, and clammy. The temperature was 96° F.; the pulse-rate 88, regular, and of good volume; and the respiration-rate 14. The blood pressure was 135/90. There was no odour of acetone in the breath, which had a heavy stale smell. No abnormal physical signs were detected in the heart; there were a few scattered râles on both sides of the chest, but it was otherwise normal. The pupils were small, equal in size, and reacted to light; the optic discs were slightly blurred at the edges; there were no fundal hæmorrhages. The tendon reflexes were present and equal on both sides; there was a bilateral extensor plantar response. The urine was found to contain sugar by Benedict's test, and Rothera's test for acetone was strongly positive; but the ferric chloride test was negative; no other abnormal constituents were found. The cerebro-spinal fluid was under increased pressure which was not measured, and was intimately mixed with fresh blood; two specimens were taken and were found to be of the same degree of coloration.

*Course.*—The pulse-rate and the temperature rose steadily and the respiration-rate fell to 12. The patient died seven hours after admission without regaining consciousness.

*Post mortem* the right cerebellar fossa contained about 2 oz. of blood. The upper part of the right lobe of the cerebellum was markedly macerated; the fourth ventricle, the aqueduct of Sylvius, and the lateral ventricles contained blood. Both the aqueduct and the ventricles were somewhat dilated. Stained sections of the cerebellum examined microscopically showed no evidence of tumour or cyst in which the hæmorrhage might have originated. It is probable that the hæmorrhage occurred from the right posterior superior cerebellar artery. No aneurysm, however, was found. The lungs were congested, but otherwise normal. The aorta showed early atheromatous changes. The spleen and kidneys were congested. No abnormality was detected in the other organs.

**CASE 3.**—A man, aged 43, a car salesman, was admitted to the hospital on Oct. 1st, 1935. His general health had been poor for two years during which time he had suffered from lassitude and fits of depression. Three weeks before admission he had had an attack of numbness in the left arm which had passed off after a few hours. For five days he had complained of headache which had become progressively worse. There had been no history of an abnormality of thirst, appetite, or micturition. On the evening of his admission to hospital he had consumed a large meal. While resting after this meal he suddenly collapsed and, after remaining inert for a few moments, became extremely violent and noisy. He did not vomit.

*On examination* he was found to be quite irrational. During the course of the clinical examination morphine hydrochloride gr.  $\frac{1}{4}$  was given, and before it had been completed he had passed into coma. He vomited once during the examination. The temperature was 95° F., the pulse-rate 80, and the respiration-rate 24; blood

pressure was 110/65. There was no odour of acetone in the breath; the tongue was clean. The apex-beat was in the fifth space  $3\frac{1}{2}$  inches from the midline, the sounds were distant, and there were frequent extrasystoles. No abnormality was found in the lungs. The pupils were somewhat dilated and reacted to light; the right fundus only was clearly seen and appeared normal. The tendon-jerks in both arms were very much increased, but were equal on the two sides. The knee- and ankle-jerks on the left were distinctly brisker than those on the right. The plantar response on the left was extensor, that on the right could not be elicited. The abdominal reflexes were present. The urine was found to contain sugar in considerable quantity by both Fehling's and Benedict's tests; Rothera's test for acetone was strongly positive, but the ferric chloride test was negative. The cerebro-spinal fluid had the appearance of pure blood and was under such pressure that a reading could not be obtained with the ordinary manometer measuring up to 300 mm.

*Course.*—Coma continued to deepen, respiration became more stertorous, and the rate fell to 12 per minute. The pulse-rate remained steady and became regular, but the volume became gradually less. The abdominal reflexes disappeared and an extensor plantar response was elicited on the right side before death occurred  $6\frac{1}{2}$  hours after admission and  $7\frac{1}{2}$  hours after the attack.

*Post mortem* the surface of the cerebral hemispheres was covered by fresh blood which filled the cranial fossæ and had penetrated to the cerebral ventricles. The hæmorrhage had originated from the left middle cerebral artery in the fissure of Sylvius, where there was considerable destruction of brain tissue. Sections of the cerebral cortex in the immediate neighbourhood of the hæmorrhage showed a marked excess of polymorphonuclear leucocytes in some of the vessels. No aneurysm was found on the middle cerebral artery itself, examination of which was difficult because its remains were embedded in clot to which they were adherent. There were a few petechial hæmorrhages into the duodenal mucous membrane. The lungs, spleen, and kidneys were congested. The heart and other organs were normal.

**CASE 4.**—A man, aged 59, a silver cleaner, was admitted to hospital on Nov. 15th, 1935. Nothing is known of his past medical history for he lived in lodgings and was without friends. It is probable that he suffered from headaches, since his urine was found to contain salicylates. On the day of admission he was found by his landlady lying in bed in a comatose condition from which she was unable to rouse him. There was no evidence of his having vomited.

*On examination* the patient was deeply unconscious; he appeared well nourished. The temperature was 97.8° F.; the pulse-rate 56, regular and of fair volume; respiration was stertorous, the rate 40. Blood pressure was 160/80. The area of cardiac dullness was normal and the heart sounds so distant as to be practically inaudible. Moist râles were heard all over the chest, which was otherwise normal. The pupils were fixed and unequal, the left being dilated and the right constricted. The fundus of the left eye only was seen; papilloedema was present, but there were no hæmorrhages. The tendon-jerks in the arms and legs were present, equal on the two sides and not exaggerated. The abdominal reflexes were absent; a bilateral extensor plantar response was obtained. The urine contained much albumin; Benedict's test for sugar was strongly positive and an immediate strongly positive reaction was obtained with Rothera's test, but the result of the ferric chloride test was obscured by the presence of salicylates. The cerebro-spinal fluid was under increased pressure, which was not measured, and was deeply and uniformly stained with fresh blood.

*Course.*—The patient died without regaining consciousness three hours after admission, and four hours after he had been found to be in coma.

*Post mortem* the seat of the hæmorrhage was found to be in the anterior part of the right parietal lobe. Here there was a cavity containing macerated brain substance and blood clot, which had ruptured into the lateral ventricle. Both lateral ventricles, the third and the fourth ventricles, contained blood. From the fourth ventricle sufficient blood had leaked to produce large collections at the base of the brain and beneath the arachnoid on the surface of

the cerebral hemispheres. There was early atheroma of the aorta, the heart was somewhat fatty, the kidneys and spleen were congested, the lungs œdematous, and the liver fatty.

#### DISCUSSION

Apart from the fact that sugar and acetone were demonstrated in the urine, and that all four illnesses were fatal, these cases have little in common. In the three in which a post-mortem examination was made the only common findings were extensive destruction of brain substance and the presence of blood or deeply blood-stained fluid in the cerebral ventricles; the site of the hæmorrhage was different in each case. It is interesting to note that the findings in Case 3 were almost identical with those described by Jamieson and Scott<sup>6</sup> in their second case. Case 1 was sent to hospital with the diagnosis of diabetic coma, having been seen by her own doctor; the true nature of the condition was revealed by lumbar puncture which was performed chiefly in view of the absence of acetone in the breath and the negative Gerhardt's test. The presence of a strongly positive Rothera's test was, at the time, thought to be due to the patient having taken no food for some 18 hours and during that time she had vomited frequently. In Cases 2, 3, and 4, however, there was no emesis before admission, and in two of them the urine was examined within three hours of the ictus. In Case 3 the patient had recently taken a large meal. It seems, therefore, that the ketonuria is not the result of starvation.

The possibility that these patients were the subjects of undiagnosed diabetes mellitus cannot be excluded. There is no evidence in support of such a conjecture, except for the history of lassitude in Case 3. It is known that the urine of Case 1 had been sugar-free a few weeks before her final illness. In the case described by Bix<sup>3</sup> and three of those recorded by Rømcke and Skouge<sup>5</sup> the patients were known to be non-diabetics.

The urine in each was obtained by catheterisation. The lubricant and the disinfectants used have been shown to contain no acetone either as part of their composition or as an impurity. The tests were Rothera's nitroprusside test and Gerhardt's ferric chloride test. In each specimen the former was strongly positive; a deep purple coloration developed almost immediately and rendered the solution opaque within the space of a few minutes. The ferric chloride test was negative in three cases and indefinite in one. It therefore seems probable that ketone bodies occurred in the urine in small quantities only; acetone alone may have been present, but that is extremely improbable.

The mechanism whereby ketonuria is produced in these cases is obscure. It seems that the hyperglycæmia following either piqûre or pathological cerebral injury is the result of sympathetic stimulation. According to Macleod<sup>8</sup> and others, glycogen is liberated from the liver as the result of stimuli reaching that organ through the hepatic nerves, reinforced by the action of adrenaline, increased secretion of which occurs following stimulation of the suprarenals through the splanchnic nerves. Hubbard and Wright<sup>9</sup> have shown that the injection of adrenaline in healthy individuals produces a definite rise in the quantity of ketone bodies in the blood. It is possible therefore that the ketonuria is the result of a massive increase in the secretion of adrenaline. An alternative theory involves the assumption that there is pancreatic dysfunction as the result of deranged nervous control. It has been shown by Clark<sup>10</sup> that the islets of Langerhans normally

receive inhibitory stimuli through the vagi. If the centres of origin of such stimuli were themselves stimulated as the result of hæmorrhage a true diabetes might result.

Bix<sup>3</sup> objects to theories suggesting central causation of ketonuria on the grounds that it has not been produced by piqûre. The stimulus acting upon a cerebral centre following an intracranial vascular catastrophe is associated with sustained increased pressure, and is of a very different order from the temporary stimulus of experimental piqûre. It is difficult therefore to uphold his argument.

One of the cases recorded by Rømcke and Skouge<sup>5</sup> showed a positive test for acetone while the tests for sugar were negative. This would seem to oppose both the theories outlined above, although as these authors point out, in a patient with small glycogen reserves the hyperglycæmia would be of mild degree and short duration. Both theories involve the acceptance of views and experimental work concerning which there is some dispute.

Be the explanation of the ketonuria what it may, it is in the difficulty of diagnosis to which it may give rise that the real interest lies. The coma following intracranial hæmorrhage may, in the absence of signs directing the attention to the central nervous system, simulate the coma of hyperglycæmia so closely that differentiation of the two conditions may be extremely difficult. It is unusual for the odour of acetone to appear in the breath following subarachnoid hæmorrhage, but its presence has been described.<sup>4</sup> In none of the cases recorded has altered intra-ocular tension been found. A negative ferric chloride test is common in these cases and, since it must be extremely rare in hyperglycæmic coma, it is valuable in differentiating the two conditions. The test was, however, found to be positive in four of the cases described by Rømcke and Skouge.<sup>5</sup>

#### SUMMARY

Four cases of hæmorrhage into the subarachnoid space are reported associated with glycosuria. In all of these ketone bodies were present in the urine in small but definite amounts, as evidenced by a strongly positive Rothera's test. The differential diagnosis from diabetic coma can be made in the absence of neurological signs by the ferric chloride reaction, which is usually negative in subarachnoid hæmorrhage; in diabetes it is almost always positive. In each patient there was extensive destruction of brain substance and the ventricles were filled with blood. It was not possible to determine whether the ketonuria was due to sympathetic stimulation, causing an excessive secretion of adrenaline, or to pancreatic dysfunction due to central irritation.

I am indebted to Dr. Anthony Feiling and Dr. Hugh Gainsborough, under whose care these patients were admitted, for permission to publish the cases, to Dr. John Taylor and Mr. Garthowen Williams for the pathological reports, and to Dr. Winterstein-Gillespie for his assistance in translating the German references.

## CLINICAL AND LABORATORY NOTES

A CLAMP FOR STRETCHING  
CONGENITAL CLUB-FEET

By M. FORRESTER-BROWN, M.S., M.D. Lond.

SENIOR SURGEON TO THE BATH AND WESSEX ORTHOPÆDIC HOSPITAL; CONSULTING ORTHOPÆDIC SURGEON TO THE DORSET AND SOMERSET ADULT TUBERCULOSIS HOSPITALS AND TO THE WILTS COUNTY COUNCIL

ONE of the difficulties in correcting the equinus deformity of a congenital club-foot is that, at the age when treatment is most advisable—i.e., in early infancy—the bones are very small and relatively soft in comparison with the dense shortened ligaments. It is therefore essential to localise very accurately the correcting force. In order to get a true dorsiflexion of the ankle, and not merely a pseudo-correction by lifting up the front of the foot at the mid-tarsal region, one must push up the front of the os calcis at the same time that one brings down its posterior end with the insertion of the tendo Achillis, thus restoring the normal tilt to its axis, which in club-foot is horizontal instead of upwards and forwards.

Some surgeons have stated that this manoeuvre can only be accomplished by pulling downward with a pin passed deep to the tendo Achillis. I have found, however, that the clamp here illustrated is equally effective. It leaves the surgeon's hands free to control the lateral movements of the foot, so that after dorsiflexion in inversion, which is relatively easy, the foot can be stretched into valgus; for, unlike the contractures of the tendo Achillis in other conditions, that in club-foot is tightest in the everted position, owing to a lateral displacement of the tendon.

In an infant whose club-foot is not yielding to regular manual stretching followed by fixation with adhesive strapping (to include the flexed knee), it is best to anaesthetise the child deeply. He is placed prone, in which position the knee is best kept free from lateral strain, and the lower leg lies vertically with the sole upward in the clamp; this is made on the same principle as those used by book-binders. A small cushion should be placed under the knee to protect the patella from bruising and the foot should be steadied so that the cross-bar of the clamp, which is convex downward, fits into the hollow just in front of the os calcis (mid-tarsal joint). While the surgeon steadies the foot, an assistant tightens the screw slowly, gradually forcing the front of the os calcis toward the table, the bone acting as a lever to bring the insertion of the tendo Achillis further from the calf. It is the slow and even stretching afforded by the clamp that is so valuable, as the surgeon's thumb is apt to tire and act unevenly

when used for a similar purpose. When used slowly, there is no bruising by the clamp nor tearing of the muscle. If it is found that there is no appreciable stretching of the tendon, as happens in the worst cases, it is desirable to tenotomise the posterior ligaments of the ankle deep to the tendo Achillis; often the external and occasionally, also, the internal lateral ligament should be divided at the same time, though, contrary to what one might expect with a varus deformity, it is the posterior fasciculus of the external ligament, rather than the internal, that obstructs dorsiflexion. The foot should be removed from the clamp for the tenotomy and then replaced, while the surgeon keeps pressure on a dressing over the tenotomy opening. This bleeds briskly for a short time, but if the tenotome has been kept close to the bone the vessels that it divides do not jeopardise the

circulation to the foot. After the ligaments are cut, the tendon is fairly easy to stretch, as one's force affects the elastic fleshy belly, which previously had been splinted by the ligaments. The advantage of not tenotomising the tendon itself is that it is always poorly developed in the worst cases of club-foot, the very ones which require manipulation under an anæsthetic, so that there is serious risk of weakening it by immediate correction after division, or by too early stretching of the scar, and it must be remembered that a calcaneus is a more disabling deformity than an equinus. If time is allowed for the divided tendon to reunite the ligaments are also reuniting. Accordingly, I have found this method of dividing ligaments and simultaneously merely stretching the muscles a very valuable one. I have never failed to get full correction of all the elements of the club-foot deformity. This is not the same thing as saying that relapse may not occur later. As I have pointed out in a recent investigation of a large number of late results,<sup>1</sup>

the bad club-foot represents not a fixed deformity like that after a badly set fracture but an impetus to faulty development, to resist which will tax all the surgeon's patience and ingenuity during the whole period of the child's growth.

As soon as the foot falls limply into the corrected position it is removed from the clamp and enclosed in plaster with the knee at right angles and the child still prone. Stockingette is applied and three pads only are inserted under it—i.e., one on the dorsum of the foot, one over the tendo Achillis, and one over the patella. Heussner's glue is then poured over the heel to prevent the ill-developed heel slipping upward and plaster is applied directly over the stockingette, very smoothly without any dragging. It is essential to mould closely, as these feet slip very

The clamp in use.

<sup>1</sup> Jour. Bone and Joint Surg., 1935, xvii., 661.

easily and then get sore; as an index of this it is useful to mark with an indelible pencil the line of the toes when the plaster is finished, when any slipping upward is noticeable at once. If the patient is going into the country, one may split the plaster up the dorsum so that it could be easily removed if serious disturbance of the circulation occurred. The bad cases have shortening of the vessels and nerves behind the ankle, as well as of the other tissues, and poor circulation is the rule. Nevertheless, with the technique described and fixation of the knee in flexion, which relaxes the popliteal vessels, no serious trouble has been encountered. In the worst cases, in which open operation has been necessary in older children, it has been noted that when the obstructions to dorsiflexion have been dealt with and the foot brought to a right angle with the leg, not only is the astragalus incongruous to the tibia, but the circulation in the foot ceased until the angle was altered to about 100°, at which point blood again flowed into the stretched posterior tibial artery. It is not clear why the relaxed anterior tibial vessels do not suffice.

### SUPPURATING DERMOID CYST OF THE GASTROHEPATIC OMENTUM

By E. N. MacDERMOTT, M.D. Dub., F.R.C.S. Irel.

JUNIOR SURGEON TO THE CENTRAL HOSPITAL, GALWAY  
PROFESSOR OF THERAPY, PHARMACOLOGY, AND MATERIA  
MEDICA, UNIVERSITY COLLEGE, GALWAY

OMENTAL dermoids are amongst the rarest of intraperitoneal lesions. Shapiro and Meyer<sup>1</sup> were able to find records of 33 cases, other than their own. I have been able to collect five further references.<sup>2-6</sup> Although dermoids and teratomata are ubiquitous in distribution, the cases of Shapiro and Meyer, and of Kowalczyk were the first such growths of the lesser omentum to be recorded.

A boy, aged 7 years, was admitted to the Galway Central Hospital with a history of abdominal pain and vomiting of two weeks' duration; the pain had increased in intensity until admission. He had a temperature of 103° F. (axillary), a pulse-rate of 138, and respiration-rate of 44. The abdomen was distended, rigid, and tender; the tenderness and rigidity were most marked on the right side, the maximum point of tenderness being about 2 in. above McBurney's point, and they were enough to prevent a satisfactory examination.

With a diagnosis of "acute abdomen," the abdomen was opened under ether anaesthesia by a right paramedian incision through the rectus, centred on the umbilicus. There was a little serous fluid in the peritoneal cavity. The caecum and appendix were normal. A firm oedematous tumour was felt in the right hypochondrium. A few recent adhesions between the anterior abdominal wall and the tumour were divided, and a tense, spherical mass about the size of a cricket ball was delivered through the wound. This was dissected free from the transverse colon, gastrohepatic omentum, and anterior surface of the pylorus, to which it was attached; it seemed to have originated in the lesser omentum above the pylorus. The peritoneum over the tumour and the adjacent structures all showed much inflammatory thickening. During removal the cyst was perforated and material flowed out exactly resembling in appearance and smell the mixture of pus and sebum found in the common suppurating sebaceous cysts; this was mopped up and the abdomen closed without drainage.

Convalescence was prolonged by an abscess of the abdominal wall, but was otherwise satisfactory, the patient leaving hospital on the 31st day in excellent general condition. He has since been readmitted with occasional vomiting and a severe secondary anaemia, which required

a blood transfusion. Six months after operation he is said to be in good health.

On section the cyst wall was found to consist of an outer layer of dense inflamed connective tissue with an inner lining of granulation tissue, the original lining having apparently been destroyed by the inflammation. Other parts of the mass consisted of inflamed connective tissue of texture varying from myxomatous to fibrous.

The great *rarity* of such cysts is emphasised by Judd.<sup>7</sup> Preoperative diagnosis must of necessity be exceptional; in point of fact the majority of intraperitoneal dermoids have been discovered during the course of laparotomy for some other concurrent or apparent lesion. In some few cases the diagnosis of mesenteric cyst had been considered preoperatively.

The *symptoms* are those of pressure on the stomach, intestine, or biliary tract, or perhaps, in the case of a retroperitoneal dermoid, of pressure on the kidney or ureter, or great vessels—when the condition might simulate an aortic aneurysm. The *signs* will be a tumour, in uncomplicated cases painless, usually smooth, sometimes fluctuant, and of varying though generally considerable mobility. Among the possible *complications*: are (1) inflammation of the cyst; (2) torsion of the omentum, described by Aviles<sup>8</sup>; and (3) acute intestinal obstruction, described by Foucault. Inflammation of such a cyst has seemingly not hitherto been described, though it is a frequent complication of the commoner ovarian dermoids; it was mentioned as a possibility by Meyer and Shapiro. The *treatment* of these tumours is of course excision, when practicable, and, if this is not possible, marsupialisation as performed by Meyer and Shapiro.

### CONGENITAL ABSENCE OF AN UPPER AND LOWER LIMB

By A. H. BIZARRO, F.R.C.S. Eng.

SURGEON TO SAN FRANCISCO HOSPITAL, OPORTO, PORTUGAL

A FEMALE child, aged 4, was brought to me a few months ago. I found that she had total absence of the right upper and lower limbs and of the left fibula and fifth toe. Free, wrinkled skin covered the right shoulder-joint. At the right hip a small pedunculated knob, like an olive, was to be found in the acetabular area; it looked like a toe and was the sole representative of the components of the right lower limb. There was a severe valgus deformity of the left foot and full, passive extension of the left knee was impossible from disuse, and was limited by about 40°.

A skiagram of the right shoulder showed a normal clavicle, a rather overdeveloped acromion, and complete absence of the glenoid. In the right hip the acetabular zone was without any triradiate formation. It is interesting to note the absence of both glenoid and acetabulum. There was a

small bone, exactly like a toe phalanx, in the skin covering the hip. The left fibula was absent, as well as the fifth toe and its metatarsal. The child uses her left upper limb in a normal fashion. There was nothing relevant in the family history.

I suggested an orthopædic boot to correct the valgus and the use of a crutch to enable her to learn to stand up and gain balance. Possibly, later she may be able to walk about, when the knee and valgus deformities have been treated.

## MEDICAL SOCIETIES

### WEST KENT MEDICO-CHIRURGICAL SOCIETY

A MEETING of this society held on April 3rd, with Dr. J. R. WYLIE, the president, in the chair, was devoted to a debate on the motion that the

#### Neurotic Patient Should be Treated by His Own Family Doctor

Dr. F. HUDSON EVANS, in proposing, said that most practitioners have several neurotic patients and although it may be said that doctors live partly by them, certainly these patients live entirely on the doctor. In treating them the doctor should remember that there is usually a reason and foundation for their state and the first necessity was a complete physical overhaul; doubtful points should be referred to specialists; and any related defect should first be treated. A disadvantage, however, of specialist treatment for these cases was the hospital attendance and the inevitable contact there with abnormal and sick people. The neurotic patient required to be surrounded by normal people, to have plenty of work and play, and little time to think about himself. An anxiety neurosis could often be dispelled by the buoyant attitude of the doctor; many people had reason to be anxious—perhaps about their business, their domestic affairs, or their legal position—and confided to their doctor troubles which they would not tell to their parson. The doctor should talk their troubles over with them and assist them as far as possible to accept what could not be altered in their position. After an accident the neurotic patient was slow to recover and then often required alternative—carrot and pitchfork—forms of treatment.

The speaker considered that the manic-depressive tended to become worse in mental hospitals but would ultimately get better if adequately treated at home. The general practitioner should remember that patients with anxiety neuroses do not commit suicide, but that it was dangerous to treat a psychosis as a neurosis. His experience of psycho-analysis was only of one case which had ultimately come to a successful issue, but he felt that the time involved and the danger of rousing sleeping dogs were serious drawbacks to this therapy. The family doctor should treat the neurotic patient as one man to another, and although he should make every effort to secure the relatives as allies he should leave them outside when interviewing the patient. He should find out about the patient's way of living and whether he read medical books and health chats; he should reassure the patient throughout his examination and summarise the findings at the end of the interview. In hysteria the symptoms might be produced and cured by suggestion, but the symptoms were the patient's means of escape from a situation; the patient did not thank the doctor for curing him of his symptoms and so returning him to the original situation.

Dr. Evans had found that the most potent remedy for the neurotic patient was severe depletion of the

pocket. It made other treatment more effective and inculcated the desire to get well. The doctor's duty was also to reassure these patients and to try to make their lives happier. He felt that such treatment should be undertaken by the family doctor.

Dr. EDWARD GLOVER said that, while formally opposing the motion, he wished to discuss the means of obtaining really competent treatment of the patient rather than the question of who should undertake it. He himself was neither in favour nor against the motion. In favour of it must be said that not only were there cases which should be treated by the family doctor, but, as Dr. Evans had said, neurotic patients always insisted on treating themselves by going to the family doctor. At the other extreme there were cases of pure neurosis the treatment of which demanded specialised training, and it was positively wrong for the family doctor to attempt it. He likened this position to an emergency of major surgery, where, except, say, on a desert island, a doctor would not undertake the treatment unless he had the skilled training and constant practice of the surgeon. Between these extremes there were two intermediate classes where the family doctor might undertake treatment. There were certain forms of special treatment, such as suggestion, hypnosis, and sidetracking, for which there was no recognised training. If the family doctor had a flair for such methods and combined them with common sense and a friendly attitude he should use his skill; but he must also have a good sense of diagnosis or he might relieve a phobia to precipitate an underlying mania.

Then there were minor types of neurotic maladjustment which the doctor might treat if he knew a few rules and they were not hard to acquire. The speaker said that in cases of classical hysteria, obsessions, and compulsions, and some sexual difficulties the usual basis of the neurosis was some violent disturbance of the instincts—not necessarily in their immediate satisfaction, but disturbances which may have lasted from infancy and childhood. When a doctor, faced with a neurotic patient, tried to enter into a patient's difficulties, to agree with his view of himself, and to give him the bottle of medicine asked for, the rapport might be good and the treatment successful. This corresponded to the carrot mentioned by Dr. Evans. In this unwitting treatment it was often best if the doctor knew little of psychotherapeutic methods. But if the doctor disagreed with the patient, even though he did not say so and used various devices to hide the disagreement, the rapport often failed and the patient was likely to become worse. It was therefore important for the doctor to know his capacity in this direction. This second type presumably corresponded to Dr. Evans's pitchfork. There were, however, some passive non-resistant cases which liked to be bullied out of their condition; but such formed only a small proportion of all cases.

Dr. Glover considered that the family doctor might help the patient in some neurotic crises where there was some obvious emotional precipitating factor. For instance, if after the death of a father the son developed a guilt neurosis reproducing the father's

illness, the case might clear up with a simple explanation; but if such cases failed to respond specialist treatment was imperative. The doctor's equipment for such cases included common sense and a big personal factor. Advice and admonishment might occasionally be used, but lying, apart from deliberate suggestion, was inexcusable. Politeness was also required, and, as these patients often received little of it, was often very effective. And the doctor had to have a fairly broad understanding of the patient's general make-up.

The speaker then mentioned the family doctor's part in the prevention of neurosis. It was now known that the foundation of neurosis lay in childhood, but unfortunately few doctors had the understanding of a child's mind, possessed by an ordinary ignorant mother of good feeling. For the doctor who had there was enormous scope in assisting children with their fears and repressions. He thought that most family doctors instead of laying down the law to mothers might well have lessons from, say, four or five sensible mothers on neurosis in childhood.

In conclusion Dr. Glover said that although the family doctor could do much for the simple case requiring kindness and sympathy, expert and highly trained assistance was absolutely essential for cases of pure neurosis. This could not be given by the general practitioner, even if he had the requisite training—partly because he had not sufficient time (the speaker often took two hours over the first interview with his patients) and partly because it was impossible to carry out psychotherapy efficiently for a few hours only of a busy day.

Dr. F. A. BEATTIE seconded the motion; he said that even Dr. Glover had allowed that three-quarters of the neurotic patients should be treated by the family doctor. There was a trend in medicine to-day for the specialist to take over more and more from the general practitioner's province and insistence on specialist treatment for neurotic cases would take half his practice from him. Sir Humphry Rolleston's oration to the society, entitled the Dumping Ground of Neurasthenia, had encouraged him in the treatment he had been carrying out—more especially of the manic-depressive. He considered that patient treatment on the part of the family doctor helped such people through their phases of depression, but it was important to explain the condition to the relatives. He thought that the greater number of neurotic cases, since they were of minor degree, should be treated by their family doctor; only the more severely affected should be passed on to the specialist.

Dr. S. S. LINDSAY defined a neurotic patient as a man who was not well adjusted to his surroundings; when one considered his surroundings one felt that the relatives and friends who pestered and exhorted him also needed treatment, and that he were better treated away from home. Before treatment such patients needed a thorough clinical overhaul, and Dr. Lindsay felt that the general practitioner had neither the time nor the equipment to assure himself that there was nothing organically wrong. Dr. Beattie had asked what would become of the general practitioner if he lost his neurotic patients; he himself would be greatly relieved.

Prof. J. WOLFSCHON (Canford University, San Francisco) considered the treatment of the neurotic patient from the doctor's and the patient's point of view. The doctor used to be poorly equipped for psychotherapy, although he used it unconsciously

on every patient he saw. Nowadays students were given instruction in the prevention of neurosis. The neurotic patient was trying to escape from life not because a particular problem had risen up to attack him but because he was born with a latent instability of his nervous system. When relieved of his neurotic symptoms he still retained his own type of being. Neurotic patients liked to talk, but the busy general practitioner usually cut them short, and so lost their rapport. This impatience in listening was driving patients to the quacks and producing in the United States various cults such as osteopathy and Christian Science. He thought that the neurotic patient was seldom frank with his family doctor for fear of information reaching his parents and relatives. The tendency of the age was to too great specialisation.

Dr. HAROLD PRITCHARD said that the general practitioner's great difficulty in dealing with these cases lay in the diagnosis. He felt that if the practitioner had been specially trained he should treat some of his neurotic patients and that it was impossible to do justice to such cases in a general hospital. Once a patient was labelled neurotic the student was liable to overlook him, but as one grew older such details became more interesting. He thought that true neuroses should receive specialist treatment.

Dr. JANET GRAY cited an example of a nurse suffering from a nervous breakdown who rapidly improved on being given more suitable work.

Dr. E. P. CAREY suggested that there should be institutions and a system of after-care, resembling those for the tuberculous patient, for the neurotic.—Dr. W. E. HALLINAN thought that if there were such sanatoria everybody would crowd into them.

Dr. C. E. BOWEN WILLIAMS mentioned that a sensible mother could do much to prevent neurosis by bringing her children up not to expect too much of life. She thought that it was the craving for affection which drove many neurotic patients to their family doctor for understanding and attention.

Dr. H. V. MORLOCK held that as a neurotic patient was not adapted to his surroundings he should not be treated in them.

Dr. C. J. B. BUCHAN said that in his search for a cure outside himself the neurotic patient was liable to leave his doctor. He knew of one woman who had in the same district changed to nine different doctors since the war.

As mention had been made of the unpleasant homes of neurotic patients, Dr. EVANS pointed out that nevertheless the patients were fond of them and were generally happiest there. He felt that these patients required especially to be away from contact with abnormal people. He was distressed to think what a colony of neurotic patients might be like.

Dr. GLOVER agreed that a family doctor had many advantages in treating neurotic patients, but he considered that a true neurosis required the greater skill of the specialist.

The motion was carried by 11 votes to 9.

---

TRAINING FOR WORK OVERSEA.—A course for the training of women for citizenship oversea will be formally opened by Sir Archibald Weigall at 4 P.M. on May 1st at 17, Carlton House-terrace, London, S.W.1. Particulars may be had from the secretary, Training of Women for Citizenship Oversea, at that address.

## REVIEWS AND NOTICES OF BOOKS

**Textbook of Gynæcology**

By WILFRED SHAW, M.D. Camb., F.R.C.S. Eng., F.C.O.G., Assistant Physician Accoucheur, St. Bartholomew's Hospital. London: J. and A. Churchill Ltd. 1936. Pp. 588. 18s.

IN recent years Dr. Wilfred Shaw has made important contributions to the pathology of certain gynæcological conditions, notably ovarian tumours and the physiology and pathology of menstruation. There is evidence here not only of careful and critical research, both pathological and clinical, but of an extensive knowledge of the literature of the subject.

In its general arrangement the book follows orthodox lines. More stress has been placed upon anatomy and physiology than has been customary in recent text-books of gynæcology, because Dr. Shaw believes that future advances are most likely to come from this direction. The histology and pathology of the ovary and endometrium are fully and clearly described, and as lucid an account as our present limited knowledge allows is given of the part played by the various internal secretions in the control of the ovarian and menstrual cycles. The assessment of the importance of uterine displacements in the production of symptoms is admirable, and will provide additional support to teachers who are constantly finding reason to emphasise the harm which may be done, and in the past was often done, by too energetic treatment of what may be a symptomless abnormality. In his discussion of the operation of hysterectomy, Dr. Shaw finds illogical the argument that total hysterectomy should be performed merely because the cervix, if it is conserved, may subsequently become carcinomatous in about 1 in 150 cases. There are certain formidable arguments on the other side.

If any criticism of this work is called for it is that Dr. Shaw has somewhat neglected the psychological aspect of gynæcology. Here more than in any branch of surgery, the mental outlook of the patient and the possible effect thereon of operative or other intervention are of extreme importance. The illustrations merit special notice. There are four plates in colour and nearly 250 figures in the text. Dr. Shaw has gone far afield for his material; he has picked the best he could find at home and abroad and has added original diagrams and microphotographs where required.

This excellent book, which is comprehensive in scope and yet not too bulky for the needs of the medical student, should achieve and hold a recognised position as a text-book.

**Treatment of Diabetes Mellitus**

Fifth edition. By ELLIOTT P. JOSLIN, M.D. Harvard, Clinical Professor of Medicine, Harvard Medical School. London: Henry Kimpton. 1935. Pp. 620. 28s.

IN the fifth edition of his well-known book Prof. Joslin has secured the coöperation of Dr. Root, Dr. White, and Dr. Marble, who have written certain sections. In the discussion on the pathology of diabetes Prof. Houssay's work receives close attention. He has shown that the pituitary gland secretes a hormone which raises the blood-sugar and counters the action of insulin. When the pituitary gland is removed from a dog, and at a later date the whole of the pancreas, the animal does not develop diabetes;

but hyperglycæmia and glycosuria can always be produced in these dogs by the injection of a pituitary extract. The exact bearing of this interesting observation on the pathology of diabetes is not yet clear. A noteworthy account of the influence of heredity is given by Priscilla White and R. Pincus. They have studied 2817 siblings and show that the inheritance of diabetes is a recessive character. Even then, at the time the figures were examined, marriage between two diabetics, between a diabetic and a diabetic carrier, and between two diabetic carriers, had led to a smaller percentage of diabetic children than would have been anticipated. Since, however, diabetes is a disease which commonly develops after the age of 40 it is possible that in investigations to be made 30 years hence the figures for the same families will more nearly approach those expected under Mendelian laws of heredity. It is suggested here that the development of diabetes depends primarily upon the transmission of a single recessive gene, but also on the operation of one or more of these secondary factors—obesity, the increased consumption of sugar all over the world, and the reduction in muscular activity associated, among other causes, with the efficiency of machinery. The dietetic requirements of healthy persons are fully discussed, and also the changes which are necessary after the development of diabetes. Prof. Joslin, in his teaching, occupies an intermediate position between the advocates of high and low content of the diet; he favours between 100 g. and 200 g. per day for a patient weighing 144 lb., the average figure of choice being 140–150 g. with protein about 70 g. and fat 50 g. to 100 g. The course and treatment of coma are discussed very fully, and special sections are devoted to gangrene, tuberculosis, and cancer. The food tables are elaborate and would be even more valuable if compiled on the basis of the different amounts of food which contain 5 g. of carbohydrate.

**1. I Knew 3000 Lunatics**

By VICTOR R. SMALL, M.D. London: Rich and Cowan Ltd. 1935. Pp. 273. 7s. 6d.

**2. Asylum**

By WILLIAM SEABROOK. London: George G. Harrop and Co., Ltd. 1935. Pp. 266. 8s. 6d.

1. THE number of writers who describe their mental illnesses grows apace. A few of these works are by practised writers who have been patients or by people with a gift for narrative: their accounts are interesting, even when they manifestly distort the occurrences which provide the main attraction of the book for many readers. Other ex-patients, accurate in their recollection and not influenced by residual features of their psychosis, are misled into fine writing, and thus manage to give an unjustified impression of falsehood. That few combine literary skill with a true picture of their own behaviour or of the life in the mental hospital is not astonishing when we remember that a distorted outlook and a faulty adaptation were the reason for their segregation. It is thus with satisfaction that we note that Dr. Small's book is not by a patient but by a psychiatrist. His description of a provincial mental hospital in the United States may be taken as accurate, though his style may not please. He regards the

mental hospital in which he worked for six years as a place in which he was "privileged by fate and fortune to view from many angles the enactment of a complex drama of romance and crime, pathos and dark tragedy," and it is in this strain that he gives a rather pinchbeck account of an experience that was doubtless genuine enough but is hardly made to seem so to the reader.

2. Mr. Seabrook writes plainly and tellingly, and provides here what is probably the best description available of what goes on in a modern mental hospital. The alcoholism for which the author sought treatment did not impair his ability to see what was happening around him and afterwards to report it accurately: he has no paranoid or crusading axe to grind, his attitude is fair, even to the doctor whom he disliked, and his descriptive powers would surely be the envy of the psychiatrists who had to record his condition. The great hospital near New York in which he spent seven months is among the best of its kind in the world. Those who have read only trivial, denunciatory, or psychologising books about the conditions of treatment of the mentally ill can see here what is actually done, its efficacy, and the impression it may make on the patients themselves.

### A Textbook of Surgical Pathology

Second edition. By C. F. W. ILLINGWORTH, M.D., F.R.C.S. Edin., and B. M. DICK, M.B., F.R.C.S. Edin., Lecturers in Clinical Surgery, University of Edinburgh. London: J. and A. Churchill Ltd. 1935. Pp. 719. 36s.

THE authors have been at pains to bring this text-book up to date. Among the sections altered in this edition are those on calcium metabolism and its relation to bone disease, the prenatal muscular dystrophies, intracranial suppuration, chronic mastitis, and endocrine disease. The lists of references at the end of each chapter have also been amended; these deserve praise for the judgment used in the selection only of key articles for insertion. It is perhaps unfair to criticise the book for omitting certain elementary sections. The authors specifically state that the text-book is intended for graduates and senior students with a certain knowledge of pathology; but even so the omission of discussions of general pathological principles, such as inflammation, leaves the vast store of information provided a little out of focus. The text is clearly written and easy to follow. The section on senile gangrene is misleading where it suggests that medical calcification, not atheroma, causes narrowing of the lumen in peripheral arteries. The illustrations are numerous and with two exceptions (Figs. 101 and 136) they are good. On the whole the book fulfils its purpose well and should prove of continued value to surgeons and advanced students of pathology.

### Sanitary Inspector's Handbook

Second edition. By HENRY H. CLAY, F.R.San.I., F.I.S.E., Lecturer in Sanitary Engineering, London School of Hygiene and Tropical Medicine. With an introduction by Prof. W. W. JAMESON. London: H. K. Lewis and Co., Ltd. 1936. Pp. 432. 15s.

THE duties of a sanitary inspector are now so varied that any text-book attempting to cover them would be so long that its intention to instruct might be defeated. Mr. Clay's first problem must thus have

been one of selection, and he has been successful in giving a well-balanced presentation of essentials. An obvious criticism is that urban conditions are given pride of place. For example, in the chapter on housing law and house inspection much space is devoted to overcrowding, which is the least important matter from a sanitary inspector's point of view, and little space to unfit and defective houses and the legal questions which may be involved in dealing with them. The structures of cowsheds and their inspection get small attention and the question of land treatment of sewage, a very practical one in rural areas, does not seem to be mentioned. It is not made clear that the methods described under house disinfection are applicable to tuberculosis, and the information in the section on graded milk requires revision. These points are noted and might well receive the attention of the author in a future edition. They do not detract from the practical value of the book, for we have here a clear and fairly put account of the various legal powers under which the sanitary inspector has to act, with practical hints how his duties should be performed. The work is clearly that of an able teacher and the book can be recommended not only to the student but to the experienced sanitary inspector.

## NEW INVENTIONS

### A POCKET TRANSILLUMINOSCOPE

ANYONE who is in close touch with clinical surgery will have seen scores of cases where the diagnosis has been vitiated, occasionally with disastrous

results, by not carrying out the test for translucency, or by carrying it out inefficiently. In the absence of a dark room a wooden stethoscope or a cardboard carton are helpful, but the former's calibre is too

small to make it reliable. The transilluminoscope here illustrated can be obtained from the Genito-Urinary Manufacturing Company at a very small cost. The rubber end-piece fits the eye accurately, and it renders eliciting the test for translucency a pleasure instead of a nuisance.

## TREATMENT WITH ACETYLCHOLINE AND ITS DERIVATIVES

THE work of DALE and his collaborators has made it clear that a large number of physiological actions are brought about by the liberation of acetylcholine, or some similar substance, at nerve-endings. This view has already shed light on such clinical problems as the action of Prostigmin in myasthenia gravis.<sup>1</sup> It is natural that interest should also have been aroused in the therapeutic possibilities of such a simple and powerful substance and in the last decade a large number of papers have been published claiming success from acetylcholine administration, mainly in vascular and gastro-intestinal conditions. So much information about pharmacological actions of acetylcholine is now available that a reassessment of its value in clinical medicine may be attempted. It is not a hormone in the sense that adrenaline is a hormone; it is not manufactured in a ductless gland nor carried in the blood stream to distant tissues, but is liberated at nerve-endings when the appropriate nerve is stimulated, after which it is rapidly destroyed by an esterase universally distributed throughout the blood and tissues. The labile nature of the compound would seem to render it at the same time an ideal chemical transmitter for physiological purposes and a substance with doubtful therapeutic applications. Carefully controlled studies on human subjects have, in fact, thrown doubt on its activity as usually administered. ELLIS and WEISS,<sup>2</sup> who studied the effects of continuous intravenous infusion, found that doses of 90 to 140 mg. a minute gave flushing of the skin, sweating, palpitation, salivation, nausea, and vomiting. The minimal effective rate of injection was found to be from 20 to 60 mg. a minute—which gives a rough measure of the rate of destruction of acetylcholine by the tissues—and the conclusion reached was that it is not a suitable therapeutic agent in diseases of the arterial system. CARMICHAEL and FRASER<sup>3</sup> have also examined the effect of intravenous doses of acetylcholine and report that single doses of 10 to 30 mg. gave the above-described subjective symptoms, slowed the heart for a few seconds, and lowered blood pressure. The effects passed off completely in less than a minute; they were abolished by atropine and accentuated if eserine had been previously given. CARMICHAEL and FRASER emphasise the great variability in the response of different individuals. Doses up to 500 mg. given subcutaneously or

intramuscularly produced no subjective sensations and had no effect on pulse-rate or blood pressure even after eserine had been administered. Presumably therefore such results as have been obtained when acetylcholine has been injected therapeutically into subcutaneous tissues or muscle must be attributed to the small and variable amounts leaking into the blood stream from the very large doses injected. The greater part is probably inactivated at the site of injection.

The defects of acetylcholine as a remedial drug have stimulated the search for substances which would produce similar but more prolonged effects. Two of these have been fully investigated—namely, acetyl- $\beta$ -methyl choline (Mecholyl) and carbaminoylcholine (Doryl). The former has an action like that of acetylcholine, but is less rapidly destroyed; it is more effective after subcutaneous injection and is active when given orally. In normal human beings it is about ten times as powerful as acetylcholine when given subcutaneously and much more constant in its action. The effects last for at least twenty minutes. ABBOTT<sup>4</sup> has shown that when given by mouth in doses of 300 mg. it relieves abdominal distension by causing contraction of the gut and increases the secretion of hydrochloric acid in achlorhydria. Of greater interest are the results obtained in cases of cardiovascular disease<sup>5</sup>; when given intramuscularly to patients with hypertension it produces a profound fall in blood pressure and may in some cases relieve headache, and in Raynaud's disease the symptoms may be relieved by its regular administration. In the treatment of paroxysmal tachycardia acetyl- $\beta$ -methyl choline appears to be of great promise. Even allowing for the notorious difficulty in assessing the value of a remedy in this disorder the results recently reported by STARR<sup>6</sup> are striking; for on 66 of the 75 occasions on which it was given the paroxysms were promptly terminated—though in some of the cases it was necessary to press on the carotid sinus while the drug was acting. The dose required was less in young than in old patients, but a dose of 10 mg. seems to be safe in any patient over 20 years of age. The second derivative, carbaminoylcholine, was fully investigated pharmacologically in 1932 by H. KREITMAIR and by H. NÖLL, but seems to have attracted less attention from clinicians. Its actions are identical with those of acetylcholine but it is heat-stable, can be absorbed from the alimentary canal, and is less readily destroyed by the tissues. DAUTREBANDE and MARECHAL<sup>7</sup> have shown that doses of only 0.2 to 0.3 mg. intramuscularly give a definite fall of blood pressure which lasts for about half an hour, and this preparation appears preferable to acetyl- $\beta$ -methyl choline where it is desired to give a drug of this type by mouth. Good results have been reported from the treatment of ozæna with a 0.05 per cent. aqueous solution of carbaminoylcholine for local application.

<sup>3</sup> Carmichael, E. A., and Fraser, F. R.: Heart, 1933, xvi., 263

A word of warning is necessary about the toxic effects which may arise during treatment with these drugs. The desired effects on the heart or vessels can rarely be brought about without some undesirable side-effects such as sweating, salivation, or (more rarely) nausea, and it is advisable to prepare the patient for such symptoms. The drugs should always be given with the patient lying down to avoid syncopal attacks, which may be brought about by the fall in blood pressure. It is wise to avoid giving them in cases of angina pectoris, since substernal pain has occurred after their use, and PAGE<sup>8</sup> has shown that acetyl- $\beta$ -methyl choline may temporarily invert the T wave in all leads of the human electrocardiogram. Their employment is also contra-indicated in patients with gastric hyperacidity. The really dangerous effects may occur in two ways. A dose of acetylcholine or its derivatives intended for subcutaneous use may be given by mistake intravenously; in this way 30 mg. of acetyl- $\beta$ -methyl choline has caused cardiac asystole for seventy seconds. Equally serious is the risk that one of the highly active derivatives of acetylcholine may be given subcutaneously in doses which would be reasonable for the unstable parent substance.<sup>9</sup> It is advised therefore that a syringe containing a full dose of atropine be kept at hand ready for intravenous administration whenever one of this series of drugs is being injected.

It seems that these derivatives of acetylcholine have a definite but restricted place in therapeutics; and it might be advantageous if they came to replace acetylcholine itself, which is always inconstant in its effects and often entirely inactive.

### CONTINUOUS VENTRICULAR DRAINAGE IN CEREBRO-SPINAL FEVER

Dr. HAMPSON points out<sup>10</sup> that, of all forms of meningitis in infants, that caused by the meningococcus offers the best chance for effective treatment—provided it can be recognised in good time. In milder cases especially, the early appearances may be deceptive, the condition being diagnosed, without lumbar puncture, as meningism. Diagnostic puncture, with removal of 1.0 c.cm. of fluid for examination, is quite harmless, and in HAMPSON'S opinion its more frequent performance would avert many tragedies. It is in the less serious cases which have been missed, and those in which treatment has been only partly effective, that the late sequel of posterior basic meningitis (recognised by G. F. STILL in 1898 as a meningococcal infection) is to be apprehended. The clinical picture, which appears to be associated with thick purulent exudate at the base of the brain, is graphically described by HAMPSON but may here be summarised in the term *opisthotonos*. Partial occlusion of the foramen of Majendie, and excessive production of cerebro-spinal fluid, lead at length to a condition of internal hydrocephalus which if unrelieved results in death, or, at best, mental defect.

If meningitis is recognised very early, intravenous injection of antimeningococcal serum may bring about rapid improvement, and HAMPSON advises the use of a mixture of the available commercial sera without waiting for laboratory findings. Because of the risk of adhesions from an "aseptic meningitis" he hesitates to employ the intrathecal route before the organism has been typed and a serum provided which agglutinates it; but the intramuscular route is unobjectionable. In the series recorded in his paper an autogenous vaccine, the initial dose of which, for fear of troublesome reactions, was not allowed to exceed half a million organisms, gave promising results in two or three cases. Daily lumbar puncture, supplemented by cisternal puncture if the lumbar tap is dry, and the introduction through the needle of a suitable serum, should be maintained until cultures of the fluid, which should be almost clear, are constantly negative; thereafter the intervals of treatment should be lengthened. Sometimes, possibly owing to the provision of complement, a single blood transfusion is dramatically successful. When complete block had occurred and all methods of withdrawal of fluid had failed, continuous ventricular drainage proved successful in 24 out of 25 cases in overcoming the block and re-establishing normal flow. Many of the children so treated were moribund; even so, 6 recovered and HAMPSON believes that earlier resort to ventricular drainage would have saved more lives. The avoidance of daily puncture, which the child comes to dread, and the relief from an irksome posture and from vomiting, make the procedure well worth while even in the apparently hopeless case.

A small opening is made in the skull over the posterior horn of the lateral ventricle; to effect this in older children a burr is required, but in infants a trocar suffices. The cannula to be inserted is mounted on a hollow trocar through which runs a hollow guide and through this again a blunt-pointed stilette, its lower end grooved and its upper end cone-shaped. The cone permits and controls the escape of fluid. The guide is pushed into the ventricle; the depth of insertion is noted and cautiously increased until the medial wall of the ventricle is touched. The depth is again noted and the guide withdrawn to the mid-point of the two readings; a sufficient depth of insertion is important. Trocar and cannula are then pushed along the guide to the same depth, usually about 3.5 cm. Slight withdrawal of the stilette permits of a slow escape of fluid and obviates a sudden fall in ventricular pressure when the trocar guide and stilette are next withdrawn and replaced by a two-way inner cannula provided with a small lateral tube for irrigation. The larger tube of the inner cannula is connected to a collecting-bottle the height of which can be adjusted to control the pressure in the ventricle. The outer cannula is kept in position by a clamp fitted with a ball-and-socket joint and a webbing strap. For the first 24 hours the joint is unclamped; contraction of the ventricle, resulting in the tube being carried forward, might injure the brain. Unless the pus is very thick, artificial irrigation is not

<sup>8</sup> Page, I. H.: Amer. Jour. Med. Sci., 1935, clxxxix., 155.

<sup>9</sup> THE LANCET, Feb. 15th, 1936, p. 391.

<sup>10</sup> Hampson, A. C.: Guy's Hosp. Rep., 1935, lxxv., 431.

called for; the cerebro-spinal fluid itself irrigates sufficiently. Serum may be introduced through the apparatus. Usually after two or three days fluid can be withdrawn by cisternal puncture, and thereafter saline and serum can be run through from ventricle to cistern. Ultimately, when the character of the fluid is satisfactory, the cannula is gradually and cautiously withdrawn, and finally the wound is closed with a collodion dressing. Dr. HAMPSON emphasises the paramount importance of expert nursing in securing changes of posture, cleanliness, and nutrition. Most of the breast-fed babies were kept on the breast—a tribute, he adds, to the nursing staff and, not least, to the mother.

### THE ADELPHI

THE demolition of the central block of the Adelphi buildings, which has for its front the famous terrace overlooking the Thames, is due to start at any moment, and the circumstances which have led up to the widely criticised action illustrate in a striking way situations that must become increasingly frequent in large cities. The claims of the old for preservation, made strong by history or sentiment, must yield to the claims of the new which arise out of the needs of developing society. That in a general way will be accepted, but acquiescence does not imply any universal endorsement of the value or virtue of the building developments now going on in the older districts of the metropolis; and the questions that are arising in London with growing frequency confront all who dwell in old and important urban communities. Two things, it would seem, should be made clear in connexion with these operations of destruction and substitution—first, that the old buildings have outgrown utility, and, secondly, that the structures which rise in their place meet real needs and have not as their justification only the making of money, whether on behalf of rating authorities or of personal speculators. The great justification of rebuilding schemes is that they promote health in the widest sense, not only by modern sanitation and amenities, but also by providing facilities for the discharge of necessary work. If these two things can be proved history and sentiment must be ignored, however regretfully. Regarded in this way no valid arguments can be advanced against the demolition of the Adelphi. The charming structures have outlived their practical utility, and in face of this fact the plea for the preservation of the picturesque cannot prevail.

The cultured and leisured sections of the population, for whom ROBERT ADAM and his brothers designed the Adelphi quarter, have left it long ago; their followers, men of literary and artistic proclivities, who gave the Adelphi throughout the nineteenth century its fascinating and slightly humorous distinction, have gradually ceased to occupy the lovely rooms, one well-known social club remaining till the end as the sole representative of this aspect. The slow desertion of the Adelphi by artists, in words or materials, by critics

and journalists and their friends and imitators, proves that the buildings no longer conform sufficiently to modern standards of life, and those who once competed for the semi-cloistered shelter afforded in an elegant example of town-planning have found in other places their more convenient if less happily situated abodes. There is therefore no widespread grievance following on dispossession, such as must be grievously felt in many quarters of London to-day, where small houses, charming in character, standing in their own greenery, and conforming entirely to the needs of their tenants, are being torn down to make place for masses of flats, generally described as offering luxury while constituting a curious commentary on what luxury means.

No medical conveniences or facilities happen to be lost by the disappearance of the Adelphi central quadrangle, and the present home of THE LANCET, with its fascinating view along the main artery of John-street, remains undisturbed. Moreover the Adelphi at no time housed more than an occasional doctor, though medical practitioners some hundred years ago found in the neighbouring streets on both sides of the Strand favourable opportunities for practice. But one doctor who lived on Adelphi-terrace made it famous in the painting world. This was THOMAS MONRO, member of a distinguished medical and artistic family. His grandfather, his father, and his uncle all made their mark in medicine, but two at least were men of high culture as well as distinguished physicians. THOMAS MONRO, himself an accomplished doctor, a leading authority on lunacy, and physician to George III. moved from Bedford-square to 8, Adelphi-terrace in 1793. He was a considerable artist and had inherited through his father or personally collected many pictures and drawings by famous eighteenth century painters, notably by GAINSBOROUGH and J. R. COZENS. The great English school of water-colour painters had its practical origin in 8, Adelphi-terrace, where THOMAS MONRO assembled a group of young artists in evening classes, lent his paintings and drawings to be copied, and stimulated in every way any promising achievement. He was astonishingly fortunate in his recruits, for among those who profited by his enthusiasm and generosity were TURNER, GIRTIN, VARLEY, PETER DE WINT, and JOHN LINNELL. How the work of these men and their followers became the starting-point of the peculiarly English achievement of water-colour painting is a well-known and interesting feature in the history of art, and the names of the Adelphi and Dr. THOMAS MONRO are thus assured of preservation.

THE Government of South Australia is collaborating with the University of Adelaide in establishing an institute of medical science. The sum of £15,000 has been privately subscribed for the purpose, and the Government will make an equal contribution. As announced on p. 927, Dr. E. Weston Hurst, of the Lister Institute, London, has been appointed the first director.

## ANNOTATIONS

## DISEASE AND WORK

At the Cambridge meeting of the Tuberculosis Association, of which some account was given in our last issue, Freiherr V. von Weizsäcker, director of the medical clinic at Heidelberg, had some provocative things to say about disease and work. At present, he remarked, we were wasting time and money in endeavouring to restore a function, instead of spending time and money in adapting the diminished or altered function to existing conditions of employment. A patient treated by a merely reparative therapy—no matter whether the primary disease was tuberculosis, concussion, ulcer, or sciatica—is apt to develop what is known in Germany as “secondary symptoms,” caused by a rupture of life’s coordination in work, wage-earning, respectability, and physical enjoyment. This “interruption factor” in recovery is usually reinforced by a number of typical conflicts of a more or less social nature, such as unemployment with its attendant poverty, disputes with a superior, family quarrels, political antagonism, or litigation, in which the patient is contesting only for his rights as such, and not for definite material advantage. Prof. Weizsäcker has in his own practice as internist and neurologist discovered the significance of these and similar factors in the treatment, not only of neurosis and incapacity for work, but even of purely “organic” disease. The definition of work is only to limited extent a question of physiological economy; even in the case of certain forms of manual labour the quality of the work—e.g., its exactitude or beauty—is of greater importance than the output of physical energy required in its performance. Capacity for work is not a question of physiological economy, but of will-power; of conditioned will, that is, not of conditioned reflexes. This being so, Prof. Weizsäcker does not find it surprising that neither the economic quotient, nor the basal metabolism, nor the absorption of oxygen shows characteristic alterations in the case of the tuberculous patient with impaired working capacity. More is to be expected from a searching social analysis than from a blood count. But then the Heidelberg professor does not regard work as a religion; in certain cases it may be better, he dares to suggest, to learn to use leisure—e.g., in reading, talking, observing, learning to think. His paper produced a remarkable impression. In the discussion which followed Dr. W. C. Fowler drew attention to the metabolic value of work, and deprecated the idea—so prevalent among patients, and even held by some doctors—that breakdown is always associated with work. It was much more often, he thought, associated with recreation. Dr. F. R. G. Heaf thought the sanatorium patient should be asked if he *liked* to do work; once his will was enlisted there was much less chance of any trouble over it. The educational side of work should be stressed.

## CHANGING ANÆSTHETICS

SOME years ago Mr. Bernard Shaw’s gibe against medical men that their anæsthetics “spare us nothing except the actual pain of operation” must have gone home. That day is fortunately past, and the patient who has to undergo an operation nowadays, whatever else he fears, need not fear the suffocation which used to precede anæsthesia or the prolonged discomfort which followed it. This improved state of affairs is due largely to the work of the chemists

and pharmacologists who have supplied the anæsthetist with effective drugs for easing the road into unconsciousness. These drugs have done more. When they have not abolished altogether the need for chloroform and ether, the two anæsthetics mostly responsible for after-effects, they have reduced the amount that has to be administered. The use and character of the various adjuvants at the anæsthetist’s disposal are well set out in a recent paper<sup>1</sup> by Dr. Frankis Evans, anæsthetist to St. Bartholomew’s Hospital. Although he applauds the methods which he describes, Dr. Evans does not fail to pay tribute to the results achieved by the older anæsthetists with their limited means, inviting us to marvel with due humility at the wizards who wielded drop-bottle and square of lint. In one respect the anæsthetist of to-day does not yet appear to have surpassed his forerunners. The patient’s comfort and the surgeon’s facility have both been enormously enhanced; we doubt whether it can be maintained that the patient’s safety has been increased to the same extent. The anæsthetist must not be content to rest on his laurels so long as ether convulsions, “status lymphaticus,” post-operative shock, and post-operative pneumonia continue to claim their victims.

## BIOLOGICAL PRINCIPLES IN ORTHOPÆDIC SURGERY

If the skeleton is regarded as still in process of evolution, with an imperfect adaptation to the erect posture and a partial obsolescence of certain of its structures, many problems of orthopædic surgery will become simpler. This is the main thesis of a paper<sup>2</sup> by Dr. George W. Hawley of Connecticut. He enunciates the general principle that “involuting structures are potentially weak and vulnerable, those in the process of evolution are particularly strong and resistant to disease and injury.” It is doubtful, however, whether this statement can be accepted in its present form. When he cites the shoulder-girdle as a structure that has largely lost its function and power in supporting and moving the body-weight—as in climbing trees—it is easy to follow him: undoubtedly the clavicle and the shoulder-joint are particularly liable to injury when the arm is held out of the pendent position. But the vulnerability of his “principle” is apparent when he describes the foot as also weak because in process of “involution.” The human foot is surely a highly differentiated structure, adapted for support and for the distinctly human function of walking. Hawley believes that the foot would be structurally and functionally stronger if all the bones below the astragalus were ankylosed. But that is to presuppose that dancing is not one of its functions. Nevertheless, it is probably right, in operations on the foot, to aim at an ankylosis, because in most feet the muscular and ligamentous elements are poor and will not be much help in rendering a foot both mobile and strong. The liability of the spine to sprains and injuries of all degrees of severity can also be related to its imperfect balance and adaptation to upright posture: spondylitis may be due to instability of the curves of the spine and the irregular strain to which they are subjected. The biological “law” is instability of form with instability of

<sup>1</sup> St. Bart.’s Hosp. Jour., March, 1936, p. 106.

<sup>2</sup> Amer. Jour. Surg., March, 1936, p. 438.

function; structures are weak which are in process of changing their form and function.

The effect of an individual injury to the skeleton is largely determined by the age of the bones and ligaments involved, and deformities are not likely to be corrected spontaneously in later life. It is a curious fact, however, that activity of bone repair differs very little at different ages. At all ages it is preceded by a retrogression to a primitive type of connective tissue, and this tissue may be in some sense "young" again. The healing of ligaments and of muscles, on the other hand, seems to be a much more perfect process in the young than in the middle aged or old. Who ever saw a child with a stiff knee after a fracture of the femur?

### SENSE OF SMELL

DURING the past year Dr. C. A. Elsberg of New York and his colleagues have been carrying out important researches on the physiology of smell.<sup>1</sup> Their objective is to devise methods which can be applied in clinical practice for diagnostic purposes in much the same way as are the refined tests for vision and hearing. There is no doubt that the sense of smell has been neglected in favour of the other two special senses, and that a suitable test might give a great deal of information, unobtainable by other methods, with regard to lesions within the cranial cavity. The idea is not new, but most of the previous tests used have been dependent on the patient's sniffing up some odorous substance, and are accordingly not clearly objective. Elsberg's method requires no coöperation on the part of the patient beyond a description of his sensations, which cannot very well be eliminated. A fixed quantity of odorous substance is placed in a bottle of known capacity so that the volume of air above the liquid is always constant. The stopper carries two tubes, one of which communicates with the patient's nostrils through an ordinary double nose-piece, while through the other tube a measured amount of air can be injected into the bottle by means of a syringe. In carrying out the actual test the nasal tube is occluded, a few cubic centimetres of air are introduced into the bottle, the pressure inside the bottle thus being raised. The patient is instructed to hold his breath and the clip on the nasal tube is opened. The result is that a puff of air is blown into the patient's nostrils, the volume and pressure of which depend on the amount of air previously injected into the bottle. With small quantities of air the subject smells nothing, but as the volume of successive injections is gradually increased he becomes able to detect the presence of an odour. He then recognises that the odour is familiar, and finally is able to identify it. (This recalls the stages in the visual perception of colour.) The least injection which leads to the identification of an odour is known as the olfactory coefficient of that odour, and this is expressed in cubic centimetres. If only one nostril is used for the test, the other being occluded, the quantity is known as the minimum identifiable odour (M.I.O.).

Preliminary tests on normal persons have revealed certain interesting facts, not the least important of which is that under standard conditions the olfactory coefficients of numerous substances are almost the same from individual to individual. Another interesting observation is that the olfactory coefficients vary as the boiling-point of the substance used, and

are therefore presumably dependent on its vapour pressure. This relationship is so constant that if the boiling-points of two substances are known, together with the olfactory coefficient of one of them, the olfactory coefficient of the other can be predicted with accuracy. The authors point out that very little is known about the properties on which odour depends, but the simplest explanation of these findings is that the amount of a substance which will dissolve in the film of liquid covering the olfactory nerve-endings depends on its partial pressure. This should also depend on a further factor—namely, the force of the "blast injection" and the degree to which this momentarily raises the pressure in the nose. This has been confirmed experimentally.

A second test is known as the "stream injection" test, whose title is self-explanatory. By this method it can be ascertained whether the substance under investigation stimulates the endings of the trigeminal nerve, and it is found that very few odorous substances which are likely to be recognised by a patient are free from a "trigeminal component." For clinical tests the actual perception of odour by each nostril, the fatigability of the olfactory sense, and the reaction to trigeminal component if this exists are determined. Although relatively few conditions have so far been investigated, it is found (1) that a neoplasm pressing on an olfactory nerve or tract increases the M.I.O. of that side; (2) in intracerebral tumours the M.I.O. remains normal but olfactory fatigue lasts longer on the side of the neoplasm—in a generalised increase of intracranial pressure the M.I.O. may be lower than normal; (3) intracerebral tumours which also press on the olfactory bulb (e.g., frontal lobe tumours) lead both to an increase of M.I.O. and a longer duration of fatigue.

This technique promises to be of clinical value. The apparatus is simple, the reagents suggested are few (namely, coffee, citral, benzaldehyde, and oil of turpentine), the procedure is harmless, and there seems no reason why it should not be widely tested.

### OSTEOPOROSIS OF ENDOCRINE ORIGIN

A CASE of localised rarefaction of bone leading to fracture and relieved by administration of ovarian extract is reported by Baumgartner and Berthoud.<sup>1</sup> The patient, a woman of 33, had had both tubes, one ovary, and the greater part of the other removed eight years previously for a bilateral salpingo-oophoritis. When first seen she complained of a painful swelling of the right knee, for which she had undergone manipulative treatment without relief. A radiogram showed osteoporosis of the upper end of the right tibia and fibula. Rest and cold compresses relieved the pain, but six months later the upper epiphyses of the tibia and fibula were fractured by a trivial fall. The fractures were reduced and the leg put up in plaster. Because the patient showed signs of ovarian deficiency—almost complete amenorrhœa and hot flushes—it was thought that the osteoporosis might be due to an endocrine imbalance, and she was treated for three months with injections of an ovarian preparation. At the end of this time it was found that new trabeculæ had been laid down and the bony structure resumed its normal radiographic appearance. According to Leriche and Policard osteoporosis follows local hyperæmia; and the fact that deficiency of ovarian secretion may cause vasomotor disturbances is obvious from the hot flushes so often seen at the menopause. In the

<sup>1</sup> Bull. Neurol. Inst., New York, 1935, iv., 1, 5, 20, 26, 31, 264, 270, 286, 479, 498, 501, 511.

<sup>1</sup> Baumgartner, J., and Berthoud, F.: Presse méd., 1936, xxiv., 495.

interesting syndrome accompanying basophil adenoma of the pituitary (Cushing's syndrome) localised rarefaction of bone is frequently found and may give rise to kyphosis or to spontaneous fractures of long bones. This condition is usually associated with loss of function of the sex glands—with amenorrhœa in the female and impotence in the male. Osteoporosis associated with ovarian deficiency does not appear to be due to generalised disturbance of calcium metabolism, for the serum-calcium level both in Cushing's syndrome and in the other cases recorded is within normal limits. It seems to be attributable rather to a vasomotor disturbance, leading to localised hyperæmia, than to disturbance of parathyroid secretion.

#### TREATMENT WITH LARGE DOSES OF ATROPINE

INTEREST in the action of large doses of atropine in man has been aroused again by the Kleeman<sup>1</sup> method of treating cases of post-encephalitic parkinsonism. Bremer's<sup>2</sup> observations, out of which this form of treatment arose, seemed to indicate that parkinsonians have an unusual degree of tolerance to this drug. D. Danielopolu and N. Radulesco in Bucharest have re-examined the problem of tolerance to atropine in man, and have applied the method of high dosage to conditions other than the post-encephalitic syndrome. Their observations were communicated at the first meeting of a new body, the Rumanian Academy of Medicine, and are recorded in a series of articles in the first issue of its journal, the *Bulletin de l'Académie de Médecine de Roumanie*. Prof. Danielopolu is the secretary-general of the Academy, which has two divisions: one is devoted to the medical and biochemical sciences and the other is concerned with medical organisation, public health, and conditions of practice.

Danielopolu and Radulesco do not consider that post-encephalitics are especially tolerant to atropine, since they were able to show that tolerance can be developed by most people if the drug is given in gradually increasing doses. Patients with pyloric ulcer were studied and were given at first injections of a milligramme (1/64 grain) of atropine a day in divided doses; the dose was raised by a milligramme a day until as much as 19 mg. a day in one case, or (averaging the dose in eight cases) 10 mg. a day was being taken. Such doses brought about surprisingly little alteration in heart-rate, blood pressure, or gastric acidity. It is believed that atropine given in this way diminishes the tone of the whole autonomic nervous system, sympathetic as well as parasympathetic, and it is proposed to apply the results to the treatment of a number of disorders such as asthma and thyrotoxicosis. Sea-sickness has already been treated successfully by this method. For short crossings it is sufficient to take 0.5 mg. (gr. 1/120) of atropine sulphate about an hour before embarking. Before long voyages, however, subjects susceptible to sea-sickness are given atropine as follows. Four days before embarking, 1 mg. is given in four doses; the dose is increased by a milligramme a day so that 4 mg. is taken during the day of departure, and this dose is maintained throughout the voyage. The dosage must be reduced gradually after the voyage ends. The administration of atropine in exactly the same way is advised before operations in which chloroform is used, for it is believed that fatalities during anæsthesia may thus be avoided, and nausea

and vomiting during recovery eliminated. If respiration stops in patients who have been prepared in this manner, pressure on the carotid sinus causes breathing to recommence without affecting the heart.

These authors remark on the dangers attached to the sale of mixtures of morphine and atropine. A morphinomaniac may mistake a mixture of morphia and atropine for pure morphia and thus receive a toxic dose of atropine. The morphia habit, moreover, is especially easily acquired by those who use a mixture of atropine and morphine, since they become tolerant to the unpleasant effects of atropine, while the atropine continues to relieve many of the unpleasant actions of morphine.

#### THE YOUNG DOCTOR IN AMERICA

Mr. G. H. Edington, addressing the students of St. Mungo's College, Glasgow, last month, is reported to have expressed the view that nowadays "there is far too much talk of remuneration" for work done by doctors. Do the recently qualified men in this and other countries agree with him, or are they inclined to regard as cant the suggestion that their professional aims are less mundane than those of their fellow-men? Certainly those practising in some European countries at the moment would not agree that the question of remuneration could safely be neglected. That is not to say that it should obsess the student, or be the motive power in his choice of a profession. Dr. Nathan B. van Etten has attempted<sup>1</sup> to discover whether young persons in the United States of America take up the study of medicine from a desire for social service or from a taste for pure science, or whether they seek merely social distinction or material gain. His comments, doubtless authoritatively, on the high code of ethic maintained by the bulk of the profession during the past 2000 years. Of the 150,000 doctors in the United States, two-thirds belong to the American Medical Association and, in increasing numbers, are joining county medical societies "prompted by a desire for group protection, by a desire to follow the currents of scientific thought and by a growing appreciation of the importance of political organization." The United States medical service, he holds, perhaps naturally, to be the best in the world. In that country institutional treatment is replacing home treatment; municipal hospitals are superseding voluntary hospitals. The time is coming, he thinks, when every citizen will be entitled to treatment in a municipal hospital and when the staffs of these hospitals will be paid for their work. These changes, if they come, will profoundly affect the private practice of the future. Nevertheless more and more young persons wish to practise medicine. The proportion of patients to doctors is already less than 800 to 1 and still twice as many doctors are licensed annually as die. Dr. van Etten thinks that too often the young doctor is ignorant of economics and the practicalities of medical problems. So abstract is his education that it leaves him no opportunity for the proper study of mankind. For this he blames the academic detachment of the teacher who "does not care for general contacts" and "fails to function as a citizen." Dr. van Etten would have the teacher prepared to teach practical economics and to be "a good mixer" at any rate with his medical colleagues in private practice. At the December examination, 190 candidates from 42 medical schools applied for 16 internships at the Morrisania City

<sup>1</sup> Kleeman, A.: Deut. Zeits. f. Nervenheilk., 1929, cxi., 299.  
<sup>2</sup> Bremer, F. W.: Deut. Arch. f. klin. Med., 1925, cxlix., 340.

<sup>1</sup> Jour. Amer. Med. Assoc., March 7th, 1936, p. 772.

Hospital. Many of these candidates had achieved considerable academic success at their various medical schools. They were asked questions of a severely practical nature and only five of them were found suitable for appointments. In answering the questions most of them concentrated on inessentials. Dr. van Etten concludes that the young doctor's social objective may not point higher than making an honest living, but if this aspiration is based on respect for a high quality of service the health of our people will be in safe hands. To achieve it, teachers must become active members of medical organisations, select fewer students, teach clinical medicine intensively, promote "inspirational preceptual contacts" (whatever that may mean) between themselves and their pupils, and finally try to develop a spirit of civic responsibility. With all respect to Dr. van Etten's views, we question whether the problem is really so serious. Assuming, fairly or unfairly, that the American medical student may lack the same measure of liberal education and intensive clinical teaching as obtains in this country, we doubt very much whether, once established in private practice, he will long remain ignorant either of practical economics or of his fellow-men.

### THE PHLYCTEN

THE phlycten, it seems, is not a specific localised reaction of the conjunctiva; it occurs also in acne rosacea, Koch-Weeks conjunctivitis, and a number of other conditions besides phlyctenular ophthalmia. The pseudophlyctens observed in tropical countries and the adult preponderance in the incidence of phlyctenosis in Japan are other points in favour of the multiple aetiology of the phlycten, which was the theme of a paper contributed by Mr. Arnold Sorsby, Dr. R. Hamburger, and Dr. L. R. Benham to the congress held this month in London.<sup>1</sup> Since 1887 Burchardt has claimed that inoculation of staphylococci can produce phlyctens. More recent work however makes it unlikely that extraneous factors are responsible; a mass of experimental evidence supports the view that the phlycten is an anaphylactic response of the conjunctiva in a sensitised subject. This sensitisation may be tuberculous or produced by a wide range of substances such as tyramine, calcium caseinate, horse serum, and cocaine. A positive tuberculin reaction is common in phlyctenular ophthalmia; among 4000 cases collected from the literature the proportion was generally between 80 and 90 per cent. A higher incidence was noted among 688 cases under the age of 6 years analysed by the authors, and in these the suggestion of tuberculous infection was re-enforced by detailed radiological study of the chest. Among 130 phlyctenular lesions under the care of Mr. Sorsby and his colleagues at White Oak Hospital, Swanley, 75 per cent. were Mantoux positive, against 20 per cent. in a control series of 122 blepharitis cases. If only cases under 6 years old were considered the corresponding percentages were 70 and 9.4. In 116 cases of phlyctenular keratitis and 87 control cases of blepharitis examined radiologically, tuberculous lesions of the chest were shown to be present in 71 and 16 per cent. respectively (with suspected activity in 20 and 3 per cent. respectively); distinctly negative X ray findings were obtained in 13 and 58 per cent. respectively. Clinical tuberculosis was however present to a much smaller extent, there being only 3 cases in the phlyctenular group. The results of stomach washings were completely

negative for a series of 50 phlyctenular cases and a control group of 8 blepharitis cases. The evidence for a tuberculous factor in phlyctenular ophthalmia was strengthened by the finding of 14 cases of active tuberculosis subsequently admitted to L.C.C. hospitals out of a series of 238 phlyctenular cases admitted to Swanley from 1924 to 1930, making a percentage of 5.9, or approximately ten times the notification rate for children of the corresponding ages. Mr. Sorsby concluded by drawing a distinction between tuberculous infection and tuberculous disease. In the great majority of cases phlyctens are to be regarded as a manifestation of tuberculous infection at an early age; phlyctenular cases, like the majority of infected children, generally overcome the infection. A larger proportion of the phlyctenular cases than of the normal child population do however fall victims to tuberculosis, probably because of their early infection. In the discussion that followed Mr. R. E. Bickerton supported Mr. Sorsby's contentions. The importance of tonsillar sepsis as an aetiological factor was emphasised by Mr. C. B. Goulden, of intestinal toxæmia by Dr. A. J. Ballantyne.

### THE NEW ERGOT ALKALOID: A QUESTION OF NOMENCLATURE

THE Council on Pharmacy and Chemistry of the American Medical Association<sup>1</sup> announce the result of their consideration of the question of the proper name to be applied to the new ergot alkaloid, which has been described by Dudley and Moir as "ergometrine," and to which the names ergotocin,<sup>2</sup> ergobasin, and ergostetrine have been applied by other investigators, who obtained the substance at about the same time. A statement recently published in *Science* and in *Nature*,<sup>3</sup> and signed on behalf of the four laboratories concerned, had settled an outstanding question by stating definitely, on the basis of comparisons of samples carried out in all four laboratories, that the alkaloids to which the four different names had been given are one and the same. It was therefore only the question of choosing one suitable name, for general application to the one substance, on which the Council had to deliberate. "It is necessary," they state, "that a suitable, non-proprietary name not therapeutically suggestive be adopted for the new alkaloid. Not one of the several names that have been proposed by the discoverers complies with these requirements."

The name ergometrine was given to the alkaloid by Dudley and Moir, in their paper containing the first description of it, as a purely scientific name. Afterwards Dudley published a full description of the method of isolating this alkaloid from ergot, and obtaining it in pure condition. This method was published for the information of anybody who desired to undertake the practical preparation of the alkaloid; and there is no reason to suppose that any method differing from it in essential particulars has, in fact, been used for this purpose. There was therefore no question in this case of any attempt to obtain for anyone a proprietary interest in the alkaloid, by secrecy, or by protection either of the method of its preparation or of the name ergometrine proposed for it. It must, accordingly, be supposed that the members of the Council on Pharmacy and Chemistry regarded ergometrine as an unsuitable name for the alkaloid, not on the

<sup>1</sup> Jour. Amer. Med. Assoc., March 21st, 1936, p. 1008.

<sup>2</sup> Ergotocin and ergostetrine are known commercially in U.S.A. as ergotrate and ergokline respectively.

<sup>3</sup> Nature, March 7th, 1936, p. 403.

<sup>1</sup> THE LANCET, April 11th, p. 842.

ground that it is a proprietary name, but on the alternative ground that it is "therapeutically suggestive." This seems to us far-fetched; it is certainly not as suggestive as the names of many more familiar alkaloids—morphine and narcotine for example. Knowledge of Greek is not so widespread that the ordinary reader will connect ergometrine with a stimulant action on the uterus; and if this is the difficulty it may be argued that the word ergot, embodied in the Council's new name "ergonovine," is equally obnoxious.

In issuing their list of New and Non-official Remedies for the guidance of the medical profession the Council do work of great value; and nothing but respect can be felt for their motives and general policy. But such a service does not, as they admit, give them a right to put aside the traditional prerogative of the discoverer to propose, for scientific use, a name for a substance which has been made or isolated as the result of his researches. The workers who in 1932 first demonstrated the existence of a hitherto unrecognised active principle in ergot, who in 1935 isolated and identified this principle as a new alkaloid, and who were the first to describe its chemistry and pharmacology in terms by which it could be clearly recognised and differentiated by other workers, named the substance ergometrine. We see no need to depart from this name. It seems a clear case for an international ruling.

#### PSYCHIATRIC IN-PATIENTS AT A GENERAL HOSPITAL

St. George's Hospital has issued the first number of a magazine called *Rebuilding*, in which the editor expresses the hope, which must be unique among editorial aspirations, that the number of issues published will be few. Three or four numbers are to appear every year until the new hospital is so well on its way that the need for such publicity comes to an end. The rebuilding of a great London hospital must interest a considerable number of people in addition to those actually associated with the institution, and we have no doubt that the energy with which the campaign to get the necessary money for St. George's is being pursued will accelerate to the point at which building operations can actually begin. The sketch plans are already made and under discussion; the number of complicated questions which have to be solved before a modern hospital can begin to arise, and the difficulties in reconciling the architectural requirements with those of the medical, surgical, and special departments make it desirable that as much time as possible shall be spent in considering them. An interesting innovation for a general hospital will be a psychiatric in-patient department—a clinic with some sixty beds to be divided between men, women, and children, which will be filled mainly from patients attending the out-patient psychiatric department. This seems to us a progressive step. Not only will it provide increased facilities for treating the many patients whose disability is really not so much physical as mental, but, almost more important, the student will be enabled to see, as at present he cannot in hospital practice, how large a part in determining the inefficiency of human beings is played by influences that cannot be classified under any of the recognised organic diseases. The young doctor beginning private practice is generally more puzzled than by any other experience by the fact that many of his patients are suffering from no definite complaint in the cure of which he has been trained. Many of

these people are in the early stages of what may become definite neuroses or even psychoses. Others perhaps could be put into no definite category of nervous disease, but are none the less in need of expert help. A department such as that outlined for St. George's should do much to teach the future practitioner to give it to this large groups of patients.

Summer Time will commence in Great Britain, Ireland, the Channel Islands, and the Isle of Man on Sunday morning next, April 19th, at 2 A.M., when the hands of timepieces should be advanced one hour. It will end on Sunday, Oct. 4th.

We regret to announce the death of Mr. John Gordon Harrower, professor of anatomy at the Medical College, and consulting surgeon to the General Hospital, Singapore, at the age of 46.

We have also to record that Prof. Robert Bárány, of Vienna and Upsala, died on April 8th. Prof. Bárány, who was 59 years of age, was awarded the Nobel prize for his work on the physiology and pathology of the vestibule of the ear, and his name is applied to tests which he described. It will be recalled that only six weeks ago he contributed to our correspondence columns a letter advocating intranasal submucous injections of calcium in the treatment of excessive nasal secretion.

## THE SERVICES

### ROYAL NAVAL MEDICAL SERVICE

Surg. Lt.-Comdr. A. N. Forsyth and Surg. Lt. (D.) H. V. Pell to *Victory* for R.N.B.

### ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. W. H. Roberts promoted to Surg. Lt.-Comdr.

### ROYAL ARMY MEDICAL CORPS

Lt. J. O'Connell to be Capt.

### TERRITORIAL ARMY

Lt.-Col. R. I. Dacre, T.D., resigns his commn. and retains his rank, with permission to wear the prescribed uniform.

Capt. C. J. L. Wells relinquishes his commn. and is granted the hon. rank of Capt.

Capt. A. D. Rope resigns his commn. and retains his rank.

To be Lieuts.: 2nd Lt. W. B. R. Monteith (late R.G.A.), T. W. Preston (late Cadet Corp., Alleyn's Sch. Contgt., Jun. Div., O.T.C.), and F. G. Maitland.

### ROYAL AIR FORCE

*Dental Branch*: Flight Lt. A. Maben to R.A.F. Hospital, Aden. The undermentioned are granted non-permanent commissions as Flying Offrs. for three years on the Active List: O. F. Brown, I. St. C. Alderdice, J. H. G. Fensom, S. Hill, R. A. Pepper, and W. A. H. Smith.

### INDIAN MEDICAL SERVICE

Capt. A. M. Fraser retires, receiving a gratuity.

The undermentioned officers have vacated appts. in India:—D.A.D.H.: Maj. J. W. F. Albuquerque. D.A.D.P.: Capt. M. K. Afridi.

The undermentioned appt. has been made in India:—D.A.D.P.: Maj. J. W. F. Albuquerque.

### ROYAL NATIONAL OPHTHALMIC HOSPITAL, LONDON.

Last year 3739 in-patients and 62,000 out-patients were treated at this hospital which constituted a record. The maintenance cost increased by £5000 and last year for the first time for seven years there was a deficit on the year's workings. Of the £167,000 needed for the enlargement, which is now practically completed, only £10,000 is still to be raised.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

### XCVII.

#### PROGNOSIS OF TROPICAL SPRUE

THE syndrome of tropical sprue is explicable in terms of a metabolic breakdown of the gastrointestinal tract characterised by malabsorption in the small intestine of such substances as fat, calcium, and glucose, and defective secretion of Castle's *intrinsic* factor. Whether this breakdown is related to primary dietary deficiency or is dependent on some underlying endocrine disturbance is unknown. The view of Castle and his colleagues, based on observations in Porto Rico, that deficiency of *extrinsic* factor in the diet is responsible for sprue is not in accord with experience of this disease acquired in other parts of the tropics. In India, for example, both Hindus and Moslems living on diets deficient in extrinsic factor develop tropical macrocytic anæmia, whereas the well-to-do European, who enjoys a diet containing adequate sources of extrinsic factor, such as red meat and eggs, acquires sprue. Similarly in Africa, when disease develops associated with a diet deficient in extrinsic factor, it is tropical macrocytic anæmia and never sprue which results.

Like pernicious anæmia, tropical sprue shows a natural tendency to remission and relapse, and in the tropics, before modern treatment was practised, it generally terminated fatally from (1) asthenia and uncontrollable diarrhœa with or without tetany; (2) profound megalocytic anæmia; (3) intestinal ulceration and perforation; (4) intercurrent disease. On the other hand, if the patient suffering from the disease could afford to return to Europe and underwent treatment which included prolonged bed rest and an initial dietary of low caloric value, recovery was not infrequent, provided the scales were not weighted against the patient by excessive age or intercurrent disease.

#### PROGNOSIS FOLLOWING MODERN TREATMENT

Granted the coöperation of the patient and the absence of intercurrent disease, patients with tropical sprue both in the primary attack and in relapse are now almost invariably restored to health by modern treatment. This treatment aims at restoring alimentary function and reinforcing demonstrable deficiencies and consists of (1) adequate bed rest; (2) a series of graded diets high in protein,\* adequate in vitamin, and low in fat and carbohydrates; (3) liver extract in adequate dosage for a sufficient period administered by the oral or parenteral route or by both; (4) calcium salts per os reinforced in some instances by vitamin D. Liver extract is not nearly so effective when given alone; unless combined with a strict dietary it often fails to relieve alimentary symptoms and anæmia.

As a routine patients should continue liver extract therapy for 3 months in doses equivalent to 1½ lb. daily for the first month, 1 lb. daily for the second month, and ½ lb. daily for the third month. A high protein type of diet including cooked liver and plenty of fruit and vegetables should be adhered to for at least 6 months after freedom from symptoms. Conditions are to be avoided and the carbohydrate and fat intake only gradually increased. If there is a

\* The caloric value of these diets varies from 700 to 3000 per day and the ratio of protein : fat : carbohydrate is approximately 1·0 : 0·3 : 1·3. Either meat (Trans. Roy. Soc. Trop. Med. and Hyg., 1930, xxiv., 131) or milk casein (Ibid., 1932, xxv., 297) may constitute the source of protein.

history of repeated relapses or any doubt regarding complete restoration of the blood to normal, an adequate maintenance dose of liver extract should be advised, the oral dosage being generally equal to ½ lb. whole liver daily or injections of Campolon (6 c.cm.) each week for another 3 months or longer if indicated.

#### INDICES TO RECOVERY

*Clinical features.*—The clinical effects of combined treatment are very obvious. The stools rapidly decrease in bulk and number and assume a normal colour and consistency. Abdominal distension and intestinal flatulence disappear and the appetite improves; cramps and tetany cease. The nutritional state of the body becomes more satisfactory; the skin assumes a normal colour and consistency, and the nails lose their brittleness. The patient puts on weight, becomes contented and cheerful, and in a period of some 8 weeks is free from symptoms and on the high road to normal health.

*Hæmatological findings.*—Provided the alimentary features are controlled by an adequate diet the response to liver extract per os (equivalent to 1½ lb. daily of whole liver) is efficacious in restoring the blood picture to normal in at least 90 per cent. of cases. A maximal reticulocyte response occurs from the sixth to the tenth day and rapid blood regeneration follows. The blood loses its megalocytic characteristics as judged by the Price-Jones curve, and normal blood counts are generally established within 2 months of beginning treatment. In gravely anæmic patients, where an early maximal response is urgently required, oral liver therapy should be reinforced with daily intramuscular injections of 6 c.cm. of campolon or another suitable preparation. A submaximal reticulocyte response and sluggish blood regeneration following the oral administration of liver suggest insufficient dosage, and are an indication for large doses of liver given parenterally (campolon 6–12 c.cm. daily). The failure may arise from (1) malabsorption; (2) insensitiveness to liver extract, a larger dose being required to get a given effect; (3) the presence of complications.

*Biochemical data.*—With cessation of diarrhœa and the reappearance of normal stools, the total faecal fat decreases, the serum calcium increases, and the glucose-tolerance curve tends to assume a normal contour. Similarly, after the administration of glucose intravenously, normal curves are found, showing that the sluggish utilisation of sugar has disappeared. The fractional test-meal in most instances also shows an improved acid secretion, though many months or even years may intervene before the curve resumes its normal shape. That secretion of intrinsic factor by the pyloric and Brunner's glands is also restored is beyond doubt, for, unlike sufferers from pernicious anæmia, many patients who have had sprue and recovered maintain a normal blood picture on a normal diet.

#### FACTORS INIMICAL TO RECOVERY

Various factors inimical to recovery, such as age, the presence of complications and of intercurrent disease, call for consideration.

*Age.*—Tropical sprue is exceedingly rare under the age of 20 years, and formerly patients contracting the disease during the third or fourth decades were regarded as having much better prospects of cure than those developing it later in life. With modern

treatment, however, old age per se does not necessarily affect the prognosis adversely; it is the concomitant degenerative cardiovascular or renal changes and intercurrent infection common to this period of life which make for anxiety. Of five patients over 70 whom I have had under observation during the past three years, only one has failed to respond satisfactorily; that patient is over 80 years of age and suffers from an enlarged prostate and *B. coli* cystitis; only temporary improvement has followed treatment in his case. Two others relapsed mildly but immediately responded to another course of treatment.

*Intestinal ulceration and other complications.*—Ordinarily the course of sprue is afebrile, but occasionally fever develops, and when it does so it is a warning signal suggestive of intercurrent disease or intestinal ulceration. The latter may be suspected from the presence of pathological exudate or occult blood in the stools, and calls for rigorous restriction of carbohydrates and fat, as distension of the bowel may lead to perforation, peritonitis, and death. Similarly, thrombosis of the cæcal veins may follow hypotension and intestinal distension and lead to local rupture and general peritonitis. Neuritis and tetany are two of the commoner complications. Both conditions clear up as the general health improves. Occasionally tetany persists, and here fat analysis will always show persistent steatorrhœa. If fat is further eliminated from the diet and the fat content of the fæces reduced to a normal level, calcium is adequately absorbed and hypocalcæmia and tetany rapidly disappear. Vitamin D and ultra-violet irradiation may be of assistance under such circumstances.

*Intercurrent disease.*—Cardiovascular degeneration, thyrotoxicosis, sepsis, respiratory infections, and *B. coli* infections of the genito-urinary tract are conditions which militate against recovery. Their existence may be reflected in a submaximal reticulocytosis and sluggish production of erythrocytes or hæmoglobin. The presence of hypochromia always suggests intercurrent disease, as does also undue lag in the production of hæmoglobin following liver extract therapy at a time when erythrocytes are being satisfactorily produced. Iron in full dosage is indicated for hypochromia, and the possibility of associated ankylostomiasis and amœbiasis must receive special attention.

Lack of response to modern treatment suggests either that the condition is not tropical sprue or that complications or intercurrent disease exist. In their absence health should be restored and no patient should to-day succumb to this disease. The position is quite the reverse with the idiopathic steatorrhœa of cooler climates, where therapy holds out little prospect of success.

#### RELAPSE AND CURE

The question of when a patient with sprue is cured is more easily asked than answered, for patients may recover from the primary attack and remain perfectly well in a non-endemic area as long as 7 years before relapsing with typical features. Statistical information is not yet available on the relapse rate, but many patients have remained well for periods up to 5 years following the treatment outlined. On the other hand, some relapse repeatedly after becoming apparently fit. Mental worry, poverty and all that it entails, indiscretions of diet, chill, and respiratory infection are factors tending to precipitate relapse. Sore tongue, abdominal flatulence, and looseness of the bowels, especially in the

morning, are danger signals and indications for rest in bed and appropriate treatment. The therapeutic response in relapses is just as satisfactory as in the primary attack.

#### RETURN TO THE TROPICS

An attack of sprue used to be regarded as a definite contra-indication to return to the tropics. Nowadays patients who have recovered may be allowed back provided (1) they have remained free from all sprue symptoms for 6 months on a normal diet; (2) the hæmatological and biochemical findings are normal throughout this period; (3) they are otherwise healthy and are under 55 years of age.

N. HAMILTON FAIRLEY, M.D., D.Sc., F.R.C.P.

Assistant Physician and Director of Pathology,  
Hospital for Tropical Diseases, London.

## MEDICINE AND THE LAW

### A Reasonable Income-tax Deduction

THE annual requirement of the filling up of income-tax forms is an opportunity for recalling a fact with which every medical practitioner may not be acquainted. The inspectors of taxes allow it to be known that the practitioner is entitled to deduct the cost of his annual subscription to a defence society when computing his professional profits for assessment under Schedule D. Where a doctor is assessed under Schedule E in respect of salaried employment, the deduction is not allowed unless membership of a defence society is a condition of the holding of the appointment. While it is not the purpose of this note to commend any particular society, it is reasonable to remind practitioners that valuable benefits accrue from membership of such bodies and that the cost of the subscription is deemed by the Inland Revenue a necessary expense for the conduct of a practice.

### Local Authority and Sale of Diseased Meat

In an astonishing case at the Clerkenwell police-court lately the corporation of the borough of Swindon was fined £10 (with an order to pay £10 10s. costs) for sending to London for purpose of sale two hind-quarters of beef which were unfit for human consumption. Last February the Wiltshire county veterinary inspector had to deal with a cow suspected of tuberculosis. On his report to the local authority the existence of the disease was confirmed by the Swindon veterinary inspector and the animal was slaughtered. The Swindon inspector examined the carcass and condemned the offal and forequarters (which were destroyed) but apparently regarded the hindquarters as good enough to be sold for human food in London. Fortunately the sanitary inspector for Finsbury detected the transaction. He found the meat affected by generalised tuberculosis and quite unfit for human food. It was condemned on a magistrate's order. In the Clerkenwell proceedings there was an uncomfortable suggestion that the Swindon officials were anxious to relieve the rates of the incidental expense of compensating the farmer and of dealing with the case. It was not, of course, the fact that the officials themselves stood to profit in any way. The local authority, under the Tuberculosis Order of 1925, became the owner of the meat. It is a horrible idea that a local authority may have a financial interest in marketing diseased food. The Ministry of Agriculture will doubtless consider the possibility of stopping this disgusting traffic.

BRITISH CONGRESS OF OBSTETRICS  
AND GYNÆCOLOGY*(Concluded from p. 865)*

Dr. DOUGLAS MILLER presided at the morning session on April 2nd when Dr. J. HEYMAN described the

**Radiumhemmet Methods and Results in  
Cancer of the Corpus**

He said that the difficulties of presenting statistics on corpus cancer related mainly to (1) its distinction from the other forms of uterine carcinoma, (2) the requirements with regard to the histological diagnosis, (3) the criteria determining which patients should be regarded as "symptom-free." These criteria were rigid at the Radiumhemmet. Cases were regarded as symptom-free only if there was both an objective and a subjective cure after five years. Written reports from the patient were useless without examination because she might feel well and yet have a carcinoma of the body of the uterus. She must feel well, be able to work, and show no palpable changes due to cancer. The standard dosage given to fundus cases was now 1500 milligramme-element hours for each of two treatments. There was no risk of rupturing the uterus in packing it, but it was sometimes difficult to remove the radium because the cervix contracted. It should therefore be anchored by strong ligature. Tests with various ligatures had been made, and Irish linen thread proved the strongest. (Applause.) Many cases of carcinoma of the fundus were combined with other forms of carcinoma, notably of the cervix or of the ovaries. The figures presented concerned only cases of carcinoma of the fundus alone. It was very difficult to attain international uniformity of classification, but it should be possible if the pathologist attached to the clinic verified every diagnosis. At the Radiumhemmet between 1914 and 1930 inclusive, 232 cases of corpus cancer had been examined with a view to treatment. Of these, 224 were treated, and had been observed for at least five years. With radiological treatment, and operation in cases of failure, an absolute cure-rate of 42.2 per cent., and a relative cure-rate—i.e., in cases treated—of 43.7 per cent., had been obtained. The relative cure-rate of the cases treated radiologically only was 33 per cent. The series included 37.9 per cent. clinically operable cases, 44.6 per cent. technically operable, and 17.4 per cent. inoperable cases. The relative cure-rate obtained in these three groups was: 55.3, 41, and 25.6 per cent. respectively, cases operated upon being included, and 41.2, 30, and 23.1 per cent. respectively, cases operated upon being excluded. In comparing the Radiumhemmet results with those obtained by surgery, the absolute cure-rate could not be used as a basis for comparison, because the initial material in the surgical and radiological series was not uniform. Conclusions from a comparison of the relative cure-rates in operable cases had to be drawn with the greatest care because of the small number of cases, particularly in the radiological statistics. Another way had been tried to find an answer to the question of operative versus radiological treatment in operable cases. In the years under review 63 cases of corpus cancer had been referred to the Radiumhemmet after radical operation, and had been submitted to

post-operative radiation. Fifty of these cases were alive and symptom-free five years after treatment, thus giving a five-year cure of 79.4 per cent. In this cure-figure, which was nearly twice as high as for those mainly radiologically treated, Dr. Heyman found support for the view that cases of corpus cancer suitable for operation should be operated upon. Meanwhile, the radiological methods of treatment should be improved. At the Radiumhemmet since 1930, a new method of intra-uterine application for treating corpus cancer had been adopted. The uterus is packed with a number of radium tubes each placed in a separate small lead capsule. Dr. Heyman described the calculation of the dosage, a new method of packing the uterus, and the technique of application, and reviewed the early results obtained with this method.

Dr. GRAY WARD agreed that classification was a great difficulty. In a joint corpus and cervix case there was a tendency to assume the growth had begun in the cervix if it were of the adeno-type, but this was not necessarily so. The absolute cure-rate was the only real criterion of results, and he defined this as the relation between the number of the cases who applied to the clinic for treatment and the number of those who survived. He emphasised the value of a personal follow-up, which was achieved in New York in at least 90 per cent. of the cases. Dr. Heyman's cases were registered by the Government and it was therefore possible to have 100 per cent. follow-up. There was an increasing tendency to prefer a ten to a five years time limit, and patients lost sight of within that time must be assumed to be dead of cancer. Dr. Gray Ward's favourite technique in the treatment of carcinoma of the fundus was hysterectomy, preceded by radium one month earlier, and followed by deep X ray treatment.

Mr. MALCOLM DONALDSON said that the radio-sensitivity of malignant disease of the corpus must be considered. Dr. Heyman had implied that the treatment was a purely physical problem—viz., the insertion of enough radium, but while the radio-sensitivity of cervical carcinoma was very high that of corpus carcinoma was very low. He had once left radium in the uterus for 14 days, and had then done a hysterectomy, when comparatively little change was found in the uterus.

Prof. C. G. LOWRY said he had had very little experience of radiotherapy, as he operated on practically all operable cases. He had had encouraging results, however, in a few technically inoperable cases. He had long thought that the association of corpus and cervical carcinoma was commoner than statistics suggested. The field for operation was widening owing to better anaesthesia and the introduction of blood transfusion.

Prof. R. J. JOHNSTONE assumed that Dr. Heyman only advocated the packing method of inserting radium when the body of the uterus was dilated.

Prof. FARQUHAR MURRAY said he had stopped operating for carcinoma of the fundus. He asked for details of post-operative radiation, and wondered whether it delayed healing.

Prof. MILES PHILLIPS said he operated whenever possible. He wondered whether carcinoma of the isthmus should be regarded as a special type, for it appeared to be particularly virulent, and operative results were poor.

Dr. HEYMAN, in reply, said that he was not convinced that there was any difference between the

radio-sensitivity of corpus and of cervix carcinoma. He thought that the reason why adeno-carcinoma was considered less radio-sensitive was that it was usually a rapidly spreading tumour. Cases of adeno-carcinoma of the cervix usually fell into groups 1 or 4 because metastases formed very rapidly. The principle in radium treatment was to cover the entire surface of the tumour with radium. He had not much use for deep X rays, but he occasionally employed them if there was any recurrence after radium. He agreed that his new packing method was only applicable in cases where there was a large uterus. It was difficult to diagnose cases arising in the isthmus without operation; in attempting to ascertain the origin of the disease he curetted the cervix and then passed ring forceps into the body. He looked upon the growth as combined only if tumour material was collected both by the ring forceps and the curette, not if subsequent curettage revealed growth in both positions.

Prof. GILBERT I. STRACHAN then reviewed the possibility of

#### Uterine Carcinoma following Radiotherapy for Benign Lesions

He reported two cases in detail, in which radium was applied for benign uterine bleeding, and the absence of carcinoma was established microscopically; amenorrhœa followed, but in one case two and in the other seven years later carcinoma of the body of the uterus followed. Prof. Strachan discussed the action of radium, on the uterus or on ovarian tissue, also the differences of morphology in corporeal and cervical epithelium after the menopause. He concluded that there was no evidence to show that the radium was in any way causative of the carcinoma. The fact that radium did not shield the patient from later carcinoma was no justification for reverting to hysterectomy in these cases, as the operative risk would be greater than the very slight possibility of subsequent carcinoma.

Mr. PERCY MALPAS read a communication on

#### Radium in the Treatment of Uterine Bleeding

based upon nearly 200 cases of benign uterine bleeding treated with radium in Liverpool and available for after-study. He discussed the subject under the headings: (a) mode of action of radium, (b) technique, (c) permanent amenorrhœa, (d) control of bleeding with conservation of menstrual and reproductive function, (e) other lesions of the uterus. The results obtained depended upon a combination of the action of the radium upon both the endometrium and the ovaries, but the only readily calculable effect was that upon the endometrium. Once a certain critical point of endometrial reaction, such as was certainly obtained with a dose of 2500 mg. hours, was attained, then the ovaries, even if incompletely irradiated, could not restore menstruation and would undergo a secondary degeneration, as happens in cases of hysterectomy with ovarian conservation. In cases where the endometrium had received a submaximal dose, the possibility of ultimate restoration of function depended upon the degree of ovarian reaction to the radium. As regards technique, he considered that the use of intra-uterine radium had outstanding advantages over other routes. The most important point in the technique was the exclusion by preliminary curettage of an early carcinoma of the uterus, since otherwise by the use of a sub-lethal dose a fibrous reaction might be set up masking its presence until

it was too advanced for treatment. Essen-Møller had had malignant change appearing later in the uterus in 6 cases out of 200 despite an initial curettage, and for this reason had given up the method, and one similar case had been encountered in the present series. Mr. Malpas held that the occurrence of such cases did not invalidate the value of the method of radium castration, but emphasised the need for thoroughness in its technique. It must be remembered that curettage might not reveal growth, but pyometra or watery discharge following irradiation should be looked on as suggesting malignancy and be treated by hysterectomy.

For the production of permanent amenorrhœa the simplicity and certainty, the freedom from undesirable systemic reactions, and the opportunity it affords of a confirmatory curettage, made it preferable to X ray sterilisation. The use of radium in sub-menopausal dosage to control bleeding with conservation of menstrual and reproductive function had a definite scope, the main limitation of the method being its uncertainty. There was no special age limit, but most patients were at menopausal age. Precautions to be taken before treatment was undertaken were the exclusion of gross inflammatory appendage disease, and the presence of fibroids if submucous and pedunculated or degenerating, or larger than a three months' pregnancy. The total dosage given was 1500 to 2000 mg. hours, rarely 2500 mg. hours. In the Liverpool series of cases the mortality was *nil* and there were no injuries. Thirty cases (16 per cent.) continued bleeding up to ten weeks. Post-irradiation carcinoma occurred in 0.6 per cent. There was late return of transient bleeding in 4 per cent. and menopause symptoms in 23 per cent. Failure to control bleeding occurred in 4 cases (2.2 per cent.). The disadvantages of temporary control of bleeding were uncertainty of dosage, the possibility of uterine scarring, and the permanent impairment of reproductive functions. In submaximal doses the effect was chiefly on the ovaries. A dose of 600 mg. hours should not be exceeded for this purpose. The risk of cervical stenosis leading to dystocia was only very slight if the dose was less than a carcinoma dose. There was probably no risk of fetal lesions following pre-conceptual irradiation. Despite much inquiry it was still uncertain whether the primary effect of radium was on the ovaries or on the endometrium. Probably if permanent amenorrhœa was produced, there was an irreparable change in endometrium whatever the effect on the ovaries, because if the dose was big enough the bleeding never recurred.

#### Miss L. MARTINDALE read a paper on the treatment of Uterine Hæmorrhage in Non-malignant Disease

with special reference to the choice of surgical operation versus irradiation by radium or X rays. She said that in deciding upon the best type of treatment for each individual case it was of primary importance: (1) to diagnose the cause of the hæmorrhage and the physical signs, (2) to consider the age of the patient and the degree to which future capacity for child-bearing was important to her, (3) to have in hand a full report of her general health. With regard to (1), Miss Martindale's study had been confined to hæmorrhage caused by metropathia hæmorrhagica, selected cases of uterine myomata, and functional, idiopathic, or essential hæmorrhage.

*Surgical operation*, either abdominal myomectomy (the operation of choice in young patients) or hysterectomy, was performed in 54.07 per cent.

of Miss Martindale's series of 762 cases. The case-mortality rate varied from 1 to 3 per cent., depending upon the type of operation and general condition of the patient. *Irradiation* was performed on 45.93 per cent. of the cases (radium treatment 9.19 per cent., deep X ray therapy 36.74 per cent.) with no mortality. Miss Martindale described the technique used by her with radium and with deep X rays. The advantages of radium treatment over operation were, briefly, the conservation of uterus and ovaries, and in many cases also of their function; and the short time spent in hospital and short convalescence. The disadvantages were nausea, occasional continuance or reappearance of bleeding, leucorrhœa (the "bestrahlungs" endometritis), and the possibility of acute nephritis. Also a case-mortality rate according to various observers of between 0.3 and 2 per cent., deaths being due to acute peritonitis or acute purulent salpingitis. Other disadvantages included the possibility of a future pregnancy, and, in that case, the effect of radium in causing stenosis of the cervix and obstruction of labour; further, the direct effect of radium on the fœtus (microcephalic idiocy). Cases were cited to illustrate these points. The conclusion was drawn, however, that pre-conception irradiation in non-malignant cases with few exceptions leads to no difficulties in labour, but that should a fibrosed cervix cause obstruction, Cæsarean hysterectomy is indicated.

*Deep X ray therapy* Miss Martindale regarded as a specific in all cases of metropathia hæmorrhagica or small interstitial fibroids. She emphasised the importance of an exact technique with careful calibration of X ray tubes and apparatus. Of 280 cases treated only 3.5 per cent. were not cured by X rays alone. There was no death in this series. In four cases hysterectomy was performed subsequently for malignancy, one 15 years after for carcinoma of cervix, one 7 years after for carcinoma of fundus, one 3 years after for carcinoma of fundus, and one 5 years after for sarcoma of fibroid. The risk of malignant disease occurring in an irradiated uterus was thus no greater than the risk in an untreated case. Miss Martindale cited mass statistics of several thousands of cases in support of her thesis that X ray treatment was superior to radium treatment. X ray therapy had no mortality, produced no resulting complications, and there was no fear of a stenosed cervix or of the stirring up of a latent adnexal inflammation. Radium therapy was, however, preferable to X ray therapy in very anæmic patients, in whom a quick cessation of hæmorrhage was important; in these cases a blood transfusion was indicated and a diagnostic curettage imperative.

Dr. HEYMAN said that there was no sharp limit between benign and malignant tumours of the ovary, and that possibly the same applied to uterine carcinoma. He thought, therefore, that the cases reported of carcinoma following treatment might have been due rather to failure in the pathological diagnosis than to subsequent development of carcinoma. As an example, he referred to a patient, aged 40, who was twice treated with apparent success by radiotherapy for large fibroids; on her return on a third occasion she was curetted and carcinoma was found.

Prof. FARQUHAR MURRAY recalled four cases of cancer following radium treatment for non-malignant conditions, and thought their presence must have been overlooked at the time. He said that 87 per cent. of cases of non-malignant uterine lesions were cured by radium, and that he always inserted radium if possible after curetting. He did not agree

that contra-indication to radium should be limited to gross pelvic inflammation; in his view it was very risky to use it if the patient had any pain at all. He also doubted the wisdom of using radium for a fibroid as large as a four months' pregnancy.

Dr. GRAY WARD thought that the failure of radium in certain cases might be due to unsuccessful anchorage of the tubes. He always threaded a stitch through the cervix and secured it at the vulva.

Mr. MALCOLM DONALDSON thought it was unjustifiable to treat a patient under the age of 40 by radiotherapy, because it was impossible to foretell the effect on the ovaries. Radiotherapy might lead to extreme menopause symptoms even in quite small dosage. The great objection to treating large fibroids by this method was that it was impossible to say whether inflamed tubes were present.

Dr. G. W. THEOBALD wondered how Prof. Strachan and Miss Martindale had satisfied themselves that radium and X ray treatment did not increase the tendency to subsequent development of carcinoma. He thought all cases should be followed up for 30 years, and then compared with the general incidence of cancer in the country.

Prof. DANIEL DOUGAL, referring to Dr. Malpas's paper, said that he used a dosage of 2000-2400 milligramme hours; 94 per cent. of his cases either had no further bleeding at all, or only during the first week or so. Flushes were present in 75 per cent., and 83 per cent. said their general health had improved. He agreed that the action of radium was very largely on the ovaries, and that it was therefore probably better to do a subtotal hysterectomy in young people.

Prof. STRACHAN could not agree that curettage was an imperfect way of examining the cavity of the uterus. It was likely that most of the patients under consideration, and the gynæcologists now present, would be dead in 30 years' time. He did not think that the action of radium was on the ovaries. He had known two patients, aged 20 and 24, die of functional uterine hæmorrhage.

Miss MARTINDALE, in reply, said she was grateful to Dr. Gray Ward for his suggestion of anchoring radium. She agreed that X rays were useless in very young women because it might be quite impossible in these cases to get amenorrhœa. She had never seen X rays do harm in the presence of inflamed tubes, but radium might be very dangerous in such cases. She agreed that the action of radium was not on the ovaries. X rays acted on the ovaries, but only on the Graafian follicles, and not on the interstitial cells.

At the afternoon session, Prof. STRACHAN presiding, Dr. GEORGE GRAY WARD spoke on

#### Reconstructive Pelvic Surgery for Genital Prolapse

He showed an interesting series of lantern slides, demonstrating among other things the importance of retaining the uterus in an anteverted position, to prevent the intra-abdominal pressure from forcing the bladder down. He said that all forms of genital prolapse must be discussed together, as they were usually associated in varying degrees. Where prolapse of the uterus itself existed it must always be corrected, or whatever operative procedure was employed—e.g., for cystocele—would be unsatisfactory. For the cure of prolapse of the uterus, the principle of reefing the base of the broad ligaments—the cardinal ligaments of the upper pelvic floor—by approximating them in front of the cervix (or its stump if

amputated), thus elevating and anteverting the uterus by throwing back the lower pole of the organ, was a *sine qua non* if the uterus was to be retained in its normal position and condition for future child-bearing. This basic principle was common to various techniques; to Donald of Manchester belonged the credit for first appreciating and employing it definitely in 1888. That the principle of the so-called "Manchester operation" was sound was not open to dispute, but Dr. Ward believed that in certain cases it should be supplemented by shortening the round and uterosacral ligaments, in order to restore all the supports and steady apparatus that have been overstretched in a prolapsed retroverted uterus. Furthermore this technique did not fulfil the requirements in *all* cases; for women past the menopause and sometimes in younger women other types of operation might be more suitable and equally satisfactory. Dr. Ward outlined some of these and reported results of operations for genital prolapse at the Women's Hospital, New York. No one operative technique, he said, was suitable for all cases. The surgeon must individualise each case and utilise the appropriate technique to correct all the defects. Approximately 95 per cent. cures could be obtained by appropriate means. It was only advisable in very rare cases to combine abdominal with vaginal operation, since this added to the mortality and morbidity of the operation. The Watkins' interposition operation was good in suitable cases; it was better than colporrhaphy in resisting stress in old women. A preliminary curettage should always be done to exclude malignancy. The Mayo operation of vaginal hysterectomy was valuable for procidentia. What remained after amputation of the cervix was practically useless. The uterosacral ligaments must be shortened and the floor of the pouch of Douglas removed to prevent enterocele. Dr. Gray Ward described his own modification of Mayo's operation. Results were very difficult to compare, since there was no agreement about time limit for cure. At Dr. Ward's clinic there had been an organised follow-up since 1918; 94 per cent. of his own cases showed satisfactory results.

Prof. FLETCHER SHAW found that any relapses were almost always due to enterocele. He did not find it necessary to do any operation other than the Manchester one, although very rarely there was so little muscular tissue in the vagina that it was necessary to combine the operation with abdominal fixation. After the menopause 97 per cent. of cases were cured of their symptoms. He only removed the uterus if it was diseased and said that in such a case the repair must be done with particular care if recurrence was to be avoided.

Prof. MILES PHILLIPS said that in young women it was sometimes best to combine a moderate anterior colporrhaphy with Gilliam's suspension. He considered enterocele was best treated by some plastic procedure after hysterectomy. He favoured combined vaginal hysterectomy with repair of prolapse.

Dr. C. KAUFMANN read a paper on the

#### Clinical Uses of the Female Sex Hormones

He said that follicular hormone was responsible for formation of genitalia and had an effect on the whole body, while corpus luteum hormone prepared the uterus for pregnancy and maintained the pregnancy. When *dosage* was under consideration it must be remembered that the results obtained from investigations on castrated women did not necessarily apply to healthy women. The results of deficiency of

ovarian follicular hormone were (1) primary amenorrhœa in which the genitalia might be undeveloped or normal and (2) secondary amenorrhœa. It was useless to try to produce *spontaneous* menstruation with follicular hormone. In secondary amenorrhœa it was essential to exclude extrinsic causes such as pulmonary tuberculosis. The results of treatment of this condition on the whole were poor, for though follicular hormone was uniformly successful in producing menstruation, this only continued in 25 per cent. of cases when the treatment was stopped. These results would probably be improved if follicular hormone were combined with corpus luteum hormone. Blood transfusion, with blood of pregnant women, was done in 14 cases of secondary amenorrhœa last year, of which 50 per cent. continued to menstruate. For sterility follicular hormone was only valuable if there were signs of deficient ovarian function—6 out of 7 such cases in Dr. Kaufmann's series had children. The type of hormonal hæmorrhage which led to repeated miscarriage might be arrested by the administration of corpus luteum hormone. His practice was to give 10 mg. of corpus luteum hormone daily for five days. For menopausal hæmorrhage, where carcinoma had been excluded, 2 mg.<sup>1</sup> of corpus luteum hormone should be given daily for five days. Threatened miscarriage and habitual abortion could be stopped by corpus luteum hormone, 10 mg. injected weekly, with a double dose during the week in which the period should have come. Ovarian therapy gave good results in climacteric disturbances; it relieved flushes, cardiac neuroses, and psychological disturbances, but objective evidence of activity must always be looked for. On pruritus vulvæ, with or without ulceration, at the menopause, follicular hormone had a marvellous effect. Dr. Kaufmann showed convincing coloured pictures of very severe senile ulceration of the vulva at the menopause, before and after treatment. He also described a case of amenorrhœa with pruritus where irritation ceased and menstruation returned after three weeks' treatment. It would be of interest to ascertain whether follicular hormone cured idiopathic neuritis at the menopause. He warned members of the congress not to expect too much, and to use hormone treatment in a rational manner.

Mr. T. N. A. JEFFCOATE spoke on

#### Organotherapy for Functional Uterine Hæmorrhage

He said that before 1930 whole gland preparations used empirically, usually by the mouth, were almost devoid of biologically active principles. His present communication was only concerned with therapeutic agents of standardised biological activity. In attempting to assay the results of the treatment of functional uterine hæmorrhage with these substances he had collected the results of over 500 cases recorded between 1930 and 1935; made inquiry into the immediate and remote results of 80 cases, treated in Liverpool since 1932, and hitherto unpublished; and considered views expressed by foreign authorities in reply to a questionnaire. The conclusions reached were that the use of oestrin was theoretically unsound. Corpus luteum and gonadotropic hormones were equally efficacious, but they were of greater value in the treatment of puberty bleeding than in the control of hæmorrhage occurring later in life. These

<sup>1</sup> One international unit of progestin (corpus luteum hormone) = the activity of 1 mg. crystalline progesterone standard. This is approximately equivalent to 4 German clinical units and to 1 to 1½ rabbit units hitherto quoted for progestin. 1 mg. of corpus luteum hormone therefore = 1 international unit.

hormones controlled the immediate hæmorrhage, but it was doubtful whether they had any action in re-establishing a subsequent regular menstrual cycle. "Anovular" bleeding, commonly associated with endometrial hyperplasia, gave the best response to this form of organotherapy, which adequately controlled hæmorrhage in two out of every three cases. It was difficult to assess the value of hormone preparations because two different observers might describe the results in the same case, one as "no response to treatment," and the other as "cured." In a collected series, only 68.7 per cent. were cured, and many relapsed. The best results with antuitrin S (gonadotropic hormone) were obtained at puberty. Of those treated at puberty, 77.7 per cent. were cured; at ages 20 to 40, 61.2 per cent.; and after 40 only 50 per cent. The best results were obtained with metrostaxis, the worst with epimenorrhœa. The dosage was 1 c.cm. daily till bleeding ceases. Unless the bleeding was cyclical it was useless to inject except when the patient was actually bleeding. Relapses did not yield so well to treatment as did the primary condition, possibly owing to the formation of antihormones, but this was not proved.

Additional short papers on this subject were read by Dr. P. M. F. Bishop, Dr. Gregor, and Prof. E. C. Dodds. Prof. DODDS stressed the danger of attributing too much significance to urine and blood analyses in these cases. These hormones were just as real as thyroxine—viz., *real chemical entities*. The only reason that the results were not better was that their use was not yet understood. Dr. BISHOP said that his experience at the Endocrine Clinic at Guy's Hospital corresponded closely with that of Dr. Kaufmann and Mr. Jeffcoate. Small doses, 1000 international units of follicular hormone daily by mouth, might control the flushings of the menopause. The dose should be kept as low as possible because care was necessary in withdrawal. Injections should only be given if oral treatment had failed. He confirmed the fact that good results would be obtained with pruritus, but warned members that this treatment might cause alarming temporary swelling of the vulva. The recent synthesis of progestin was a very great advance and had led to a reduction in price.

On April 3rd, the concluding day of the congress, papers were read by Dr. Leonard Colebrook (Prevention of Puerperal Sepsis), Dr. H. R. MacLennan (Contracted Pelvis in Scotland), and Dr. G. W. Theobald (Relationship between Pregnancy and Chronic Nephritis).

## UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

### CASE FINDING IN TUBERCULOSIS

You have recently (March 7th, p. 561) drawn attention to the use of tuberculin tests with X ray follow-up of positive reactors as a routine method in the Scandinavian countries for early diagnosis of pulmonary tuberculosis. The same method is now in use in the United States. It is being tried on a State-wide scale in New Mexico where three organisations have pooled their resources in order to extend the early diagnosis campaign, not only to every institution of higher learning in the State but also, so far as is practicable, to senior high school students as well. The Mantoux test, using the new P.P.D. tuberculin, is given to all students. A single X ray chest film is taken of all those who react positively.

Coöperating in this survey are the New Mexico Bureau of Public Health, the Maztag Research Laboratory of the South-western Presbyterian Sanatorium, and the New Mexico Tuberculosis Association. The survey is regarded not only as a public health measure for early diagnosis but as an interesting project in clinical research. For more than a generation now health seekers in all stages of pulmonary tuberculosis, and from all parts of the United States, have flocked to New Mexico in the expectation that its climate would enhance their chances of recovery. Hundreds of these pilgrims have indeed recovered and now direct the business and take a large part in the professional activities of the State. Thousands, of course, lie buried in New Mexico cemeteries, and of these less is remembered than of the more fortunate survivors. Probably no one will ever know whether and to what extent climate has contributed to the quota of those who regained their health. But another question presents itself: What is to be the effect of this mighty pilgrimage upon succeeding generations of New Mexico citizens? A survey made two years ago showed that whereas twice as many English-speaking (i.e., in the broad sense immigrant) citizens suffer from active tuberculosis as do the Spanish-speaking (indigenous) citizens, nevertheless among the children of the former only one-half as many react positively to the Mantoux test as among the children of the indigenous group. The present study is expected to tell what is the heritage of early adult type tuberculosis among the generation of offspring who have at present reached undergraduate age. It will also tell the cost of this method of case-finding in the undergraduate age-group.

Ulster county, New York, has developed a very economical method of case-finding by X ray. They first use the fluoroscope on positive reactors and then subject suspicious chests to photography. The proportion of films used to cases fluoroscoped is 11 per cent. Up to November of last year 8000 tuberculin tests had been given, 1956 fluoroscopic examinations made. This last figure represents 652 grade school-children positive to the tuberculin tests, and 804 parents of these children, together with 500 high school-children. The cost of discovering active tuberculosis has averaged \$7 per case. Four cases were found in the grade school group, 6 in the high school group, and 26 among the parents. In addition 18 "suspicious" cases were recorded and 29 non-tuberculous but pathological conditions were discovered. This investigation in Ulster county, N.Y., has now progressed into its fourth year.

### TRENDS OF MORTALITY

Complete returns in last year's mortality are not yet available, but all indications point to another year of low mortality. Indeed, the wage-earning population as represented by the 17 million policy-holders of the Metropolitan Company in Canada and the United States have achieved an all-time low record of 8.4 per 1000. It is a remarkable fact that the rate in this group has been 7 per cent. lower in the depression years 1930-35 than it was in the prosperity years 1924-29. The tuberculosis death-rate last year reached 55.6 per 100,000, a reduction of 6.4 per cent. below the previous low record in the previous year. Again it is remarkable that the tuberculosis death-rate should have continued its decline among wage earners throughout the depression and even declined at an accelerated pace. Death-rates from diarrhoeal diseases, chronic nephritis, and causes incidental to childbirth also reached new minima. Rates for cancer, diabetes, and heart

diseases were lower than in 1934. The death-rate from alcoholism is the lowest in many years; there has been a marked decline since the repeal of prohibition.

## SCOTLAND

(FROM OUR OWN CORRESPONDENT)

### THE HEALTH OF SCOTLAND

THE seventh annual report of the Department of Health for Scotland, which has just been published, shows a general death-rate of 13·2 per thousand, which is slightly higher than last year's. The maternal mortality-rate was 6·3 per thousand births, which approximates to the average for the past five years. The urgent need of improvement in the standard of midwifery is emphasised and it is apparent that the need for antenatal supervision is not sufficiently realised by the general public. The number of deaths of infants under one year of age again reached a low record rate (76·8 per thousand births). The general health of the population was maintained, but the incidence of sickness among insured persons remains high, there being a total of over 18,500,000 days of unfitness for work among insured persons. The output of houses by local authorities was 18,651, which was the highest ever achieved in Scotland. Of these, 15,000 were built under slum clearance schemes.

### THE "EDINBURGH MEDICAL JOURNAL"

The current issue of the *Edinburgh Medical Journal* records the resignation of the editor, Mr. Alexander Miles. For no less than 25 years Mr. Miles has skilfully supervised its publication and has maintained a high scientific and academic standard. As a surgeon, teacher, and administrator he has done important work and his long and successful editorship constitutes a further service to medicine of which the members of the Edinburgh school are highly appreciative. Dr. A. Rae Gilchrist, who takes over the duties of editor, has our best wishes for the prosperity of the journal.

It is 131 years since the *Edinburgh Medical and Surgical Journal* was issued as a quarterly magazine under the editorship of the younger Andrew Duncan. In January, 1841, the *Edinburgh Monthly Journal of Medical Science* made its appearance. Later in the same year its name was altered to the *London and Edinburgh Monthly Journal of Medical Science*, and in 1846 it became simple the *Monthly Journal of Medical Science*. The latter was amalgamated with the *Edinburgh Medical and Surgical Journal* in 1855, and in July of that year the *Edinburgh Medical Journal* made its first appearance as the successor to both the periodicals. The first editor was Henry Duncan Littlejohn, professor of medical jurisprudence. A further alteration in the journal has been that since 1922 the transactions of the Medico-Chirurgical and Obstetrical Societies have been published within its covers.

### NEW FACILITIES FOR OPHTHALMOLOGY

The late Dr. Gavin Paterson Tennent, formerly a physician to the Western Infirmary, Glasgow, directed his trustees to pay over to the University of Glasgow a sum sufficient to found a chair of ophthalmology, and also allocated a sum to provide, in connexion therewith, a suitable building at the Infirmary. The new ophthalmological department thus established, which has cost £45,000, was opened last week. It is in charge of Prof. A. J. Ballantyne

and is to become a centre of higher study and research. It should be of great value since it will provide opportunities for advanced study in ophthalmology which are at present not easily obtained.

### A PUBLIC ASSISTANCE MEDICAL SERVICE

A new medical service for the poor has been set up in Clydebank. Since 1930 the service has been carried on by dividing the burgh into three districts and appointing a part-time officer for each. The number of visits and consultations in a year has been about 12,500. Under the new scheme a panel of 14 local practitioners has been formed and these will be paid, according to the number of visits and consultations made during the year, from a pool of £900 to be divided annually by the town council.

## IRELAND

(FROM OUR OWN CORRESPONDENT)

### COMPULSORY RETIREMENT OF THE OFFICERS OF LOCAL AUTHORITIES

A FEW weeks ago the Minister for Local Government and Public Health of the Irish Free State issued to all local authorities throughout the country a circular letter in which he advised them that officers in their employment should normally be compulsorily retired at the age of 65, and that in some cases, examples of which were given, the retiring age should be 60. As a retiring age was not mentioned in the terms of appointment of any of the officers concerned, much discontent was roused, and some doubt expressed as to the powers of the local authorities to compel retirement. The Minister has been asked in the Dáil to quote the statutory powers possessed by local authorities which would enable them to follow his advice, but he did not respond. He admitted that his circular was not an order, but merely a recommendation, a point which had been misunderstood by many of the local authorities. Further questioned as to whether a local authority had power to retire an officer compulsorily on the ground of age alone, he replied that other circumstances would be taken into account. Last week it was reported in the daily press that the central council of the Local Government Officers' Union had taken the opinion of senior counsel as to the legality of the Minister's action. The opinion of Mr. M. J. Ryan, K.C., as quoted in the press, was to the effect that the action of the Minister was ultra vires and that the circular need not be acted on by local authorities, as there was no law by which compulsory retirement could be enforced. Should the department advise a local authority to retire an official on reaching the age of 65, the authority could refuse to do so, and the only step then open to the department would be to call for the retirement of the official on the grounds of incompetency or incapacity, and the whole circumstances would have to be investigated. Counsel's opinion, as quoted, does not appear to deal with the situation which would arise if the local authority were willing to follow the Minister's advice, but the officer refused to retire. It seems unlikely that the Minister should have acted without making sure of the legal position, but his reluctance to answer questions in the Dáil suggests that he is not quite satisfied on the point. Should the compulsory retirement be made effective it will press hard on medical men who had entered public service relatively late in life, for the pension depends on the number of years' service.

## PROGRESS OF PHYSIOTHERAPY

A LUNCHEON was held at the Langham Hotel, Portland-place, on April 8th, in connexion with the coming International Congress of Physical Medicine to be held on May 12th-16th. Lord Horder presided and took the opportunity of making a presentation to the principal guest, Dr. Richard King Brown, medical editor of the *British Journal of Physical Medicine*, in recognition of his services to physiotherapy. Lord Horder gave a short account of Dr. King Brown's career—his ten years as medical officer of health in Bermondsey, the foundation in 1926 of the first municipal solarium in London, his translations of notable German works on his specialty, and, latterly, his arduous work for the *Journal*. Referring to the Sixth International Congress, he said that the decision to hold it in London was a tribute to the work of the English group and would give a great fillip to the march of physical medicine in Great Britain. The help and sympathy received from the Foreign Office and from the Ministry of Health had been very valuable, and 30 of the 35 countries invited had already accepted. He himself had the privilege of being honorary president of the Congress, but he very much regretted that he would not be present, because some time before the dates had been arranged he had accepted an invitation to visit America.

Lord Horder said that he had advocated the claims of physical medicine in season and out of season. He welcomed the Congress because it would stimulate this growing branch of preventive and curative treatment. Physiotherapy was not a new form of medicine; he believed that it was the oldest, for when Adam delved it was the first attempt to keep fit, though psychotherapy might claim Eve's spinning as the first contribution making for equanimity. It was only recently, however, that control had become absolutely essential. The wealth

of methods and apparatus almost made him hope that nothing more would come, to allow breathing space to test and prove the means already available. Physical medicine went on from strength to strength; its achievements had been considerable, its potentialities were incalculable. The pitfalls, however, were perhaps more and deeper than in any other branch of medicine. The greatest was the temptation, enhanced by the public's faith in machinery, to apply it indiscriminately to all types of disease. There was also the danger of the physiotherapist losing touch with the physicist on the one hand and with the clinician on the other. Ideally, of course, he ought to be both but he ought still to look for guidance and support from each; he had much to teach them, but he had also much to learn, and there was no end to learning. Another danger was that he might wander from the bed-rock of pathology and lose himself in the sea of speculation; or, worse, he might construct a pathology of his own, which could only be a pseudo-pathology. There was, lastly, the peculiar danger that he might be commercialised by the astute business man. The only real safeguards from these pitfalls were those that applied to all branches of medicine—namely, the integrity of the practitioner; colleagueship and all that it implied; the group spirit, which was essential to advance; and the opportunities given for free discussion, criticism, and the dissemination of knowledge and improved technique. The Congress would help to establish these.

Dr. King Brown replied, thanking the president for his tribute and for the presentation. He had begun his work of editing the *British Journal of Physical Medicine* with little knowledge of journalism and its success, he said, was due to the help he had received. It was the only one of its kind in the English language.

Sir Francis Fremantle proposed a vote of thanks to Lord Horder and said that the coming Congress would be a valuable contribution at this time to international peace and goodwill.

## PANEL AND CONTRACT PRACTICE

### Fitness for Work: Who Decides?

Dr. A, an insurance practitioner in Scotland, certified a patient to be unfit for work. The approved society referred the case to the regional medical officer who certified him not unfit. The man again consulted Dr. A who advised him to try some light form of work, but the patient decided not to do so and appealed to the Scottish Department of Health against the R.M.O.'s decision. In the meantime, pending the result of the appeal, Dr. A continued to issue certificates of incapacity. In due course the medical service subcommittee considered the matter and according to the *Journal* of the National Association of Clerks to Insurance Committees "decided that the insurance practitioner should not have given unfit certificates after the regional medical officer had given a contrary opinion." Eventually the committee decided that the doctor had failed to comply with the terms of service and recommended a deduction of five guineas from his capitation fees. If the facts are as stated this decision is extraordinary. What probably happened is that the decision against Dr. A was taken because he had given certificates of incapacity after he had himself concurred in the R.M.O.'s opinion of the case to the extent of advising the patient to try some light form of work. The functions of the R.M.O. in rela-

tion to incapacity for work are advisory, and the responsibility for deciding whether a certificate of incapacity should be issued or not rests with the insurance practitioner. If he is honestly of the opinion that the patient is incapacitated for work, even though the R.M.O. is of contrary opinion, the practitioner should continue to certify if the patient so requests. Whether benefit should be paid or not rests not with him but with the approved society.

### A Distinction Without a Difference

A case recently reported to an insurance committee has attracted considerable attention in the lay press. An insured person, who was a maid in the employ of a lady of title, had been suffering from quinsy, and Dr. B upon whose list her name appeared had attended her until Saturday, Feb. 29th, on which date he visited her twice. On the Sunday Dr. B received a telephone message requesting him not to call that day. On the Monday he called at the house and was informed by the housekeeper that he could not see the patient, whereupon he gave the housekeeper to understand that it was necessary that he should do so. Dr. B was then told that if he did not go away the police would be called in, and he, therefore, communicated with the insurance committee stating that he could not hold himself responsible for the patient's treatment. The

committee wrote to the employer recapitulating the facts and pointing out that an insurance doctor is required by his terms of service to visit at his or her place of residence any patient whose condition so requires, but that owing (it would appear) to the housekeeper's attitude Dr. B had been prevented from fulfilling his obligations. The employer was invited to offer any observations she might deem proper on the circumstances. A letter received from the employer's private secretary indicated that the first time the secretary saw Dr. B she "distinctly told him that, as Her Ladyship wished the patient to have the very best attention, he need not treat her as a panel patient but as a private patient, and to send a note of his fees, in due course, which if he will do in respect of the calls he made, he will be paid at the ordinary medical rate." The letter went on to say that subsequently the patient wished to be seen by the family doctor and upon the employer's instructions his services were requisitioned.

There is no reason to doubt that in this case the employer genuinely wished to do the best thing possible for her employee, but it is unfortunate that what was described, at the meeting of the insurance committee, as the atmosphere prevalent at the commencement of the last reign, should still be in evidence. Under Clause 8 (1) of the terms of service, the treatment which a practitioner is required to give his patient comprises all proper and necessary medical services other than those involving the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess. Moreover, under Clause 10 (1), a practitioner is not permitted to demand or accept any fee or other remuneration in respect of treatment which he is required to give under the terms of service. The report of the sub-committee which dealt with the matter notes the employer's view that the medical treatment available under the Act is inferior to that which a person would receive if treated as a private patient. It also notes that the reports submitted to the insurance committee from time to time with regard to the treatment provided by insurance practitioners for insured persons—e.g., the nature of medicaments and preparations ordered at the cost of insurance funds—should go far to dispel the idea that there is any difference between what is popularly known as "panel treatment" and that which a private patient would receive. A letter has been sent to the employer pointing all this out and deprecating her action, taken doubtless in ignorance, in having invited the practitioner to treat an insured person on his list as a private patient. It rests with insurance practitioners themselves to demonstrate that there is no difference between the treatment provided for their insured patients and that provided for their private patients.

**BRITISH EMPIRE CANCER CAMPAIGN.**—The 58th quarterly meeting of the grand council was held in London on April 6th, when it was announced that the King had been pleased to become patron of the Campaign. Invitations to become members of grand council were extended to, among others, Lady Barrett, M.S., and Sir David Wilkie, F.R.C.S. The following grants, amounting to £5530 and making a total to date of £30,990 for the year 1936, were approved: £1100 to the Radium Beam Therapy Research; £1750 (in addition to the grant of £1850 already made for the year 1936) to the Mount Vernon Hospital; £500 (in addition to the grant of £600 already made for the year 1936) to the Marie Curie Hospital; £100 and £80 to Dr. C. R. Amies, at the Lister Institute, and Dr. P. R. Peacock, of Glasgow,

## OBITUARY

### ALFRED MASON VANN, M.R.C.S. Eng., L.S.A.

Dr. Alfred Vann, for many years medical officer of health for Durham City, was born in Durham and began his medical training as a student at the local hospital, but proceeded for its later stages to King's College Hospital, London, where he obtained a Warneford scholarship. He qualified as M.R.C.S. Eng., L.S.A. in 1883, but did not complete his university course although he took honours in the preliminary scientific and intermediate M.B. Lond. examinations, while he also gained the silver medal in botany from the Society of Apothecaries, London. He began practice in Durham nearly fifty years ago and promptly made his mark, holding within a short space of time a local post under the poor-law as medical officer and public vaccinator, then surgeon to the Durham City Constabulary, and then surgeon to the Durham County Hospital. Simultaneously with these appointments he was elected medical officer of health for the city, a post which he held for 34 years, resigning in 1918 but retaining his position of medical inspector of school-children under the city education committee. He also took charge of the X ray and electrotherapeutic department of the county hospital where on retirement he was appointed consultant. Dr. Vann was a man of considerable accomplishments. He had edited certain sections of "Bentley's Botany," he contributed interesting cases to the *Transactions of the Northumberland and Durham Medical Society*, and had marked artistic talents. He was 75 years of age.

### SIDNEY ISAAC PRITCHETT, L.R.C.P. Lond., M.R.C.S. Eng., D.P.H.

Dr. Sidney Pritchett, who died recently in Rochester, was born in the old cathedral city and educated at King Edward's School, Birmingham. He received his medical training in Birmingham and at St. George's Hospital, qualified in 1890, and held several resident appointments at Queen's Hospital, Birmingham. He was for a time in the P. and O. service, but went into practice in Rochester nearly forty years ago and soon became a prominent civic official. He was appointed full-time M.O.H. for the city in 1902, school medical officer, and medical officer to the city and port. He was also surgeon to St. Bartholomew's Hospital, Rochester, and medical officer to the Rochester and Chatham Joint Hospital (the St. William's Hospital). He resigned these posts in 1934, having thus been in charge of the city's health services for 32 years, and was the recipient of gratifying public appreciations. He was a bachelor and 70 years of age at the time of his death.

respectively, for the purchase of special types of centrifuges; £1000 to the Manchester Committee on Cancer to cover the cost for two years' investigations into the possible connexion between the use of heavy oils in motor vehicles and the apparent increase in the incidence of cancer of the upper air-passages and the lungs; £1000 to the North of England branch of the Campaign to meet the cost for the second year of the short-wave investigations being carried out at Newcastle, on behalf of the Campaign, under the direction of Prof. W. E. Curtis and Mr. F. Dickens, D.Sc.

Notification was received that the Royal Society and the Medical Research Council had nominated Prof. Matthew Stewart to succeed Prof. R. T. Leiper, F.R.S., who has retired, as one of their five nominees on the scientific advisory committee of the Campaign.

## CORRESPONDENCE

## PROPHYLACTIC ENUCLEATION OF LOWER WISDOM TOOTH FOLLICLES

To the Editor of THE LANCET

SIR.—In my lectures before the Royal College of Surgeons<sup>1</sup> I have produced the evidence of 622 case-reports of abnormality and complication of the third molars in support of my contention that, cramped

FIG. 1.—Skiagram of a male, aged 21, showing the type of impaction which may be expected to result if the germ of the wisdom tooth shown in Fig. 2 continues to maturity.

as they are for room in the modern jaw, these teeth when mal-erupted constitute a definite clinical menace. The mandibular tooth is responsible for much the greater number of complications as well as the larger proportion of grave ones. The abnormality is dental—but the complications are medical and surgical. They range from severe and incapacitating neuralgias of one or other of the branches of the trigeminus to grave spreading infections involving the cavernous sinus or the mediastinum

FIG. 2.—Skiagram of a female, aged 9½, showing the germ of the wisdom tooth already badly inclined in the "impacted position." This also shows the latest optimum stage of development at which enucleation is best performed.

<sup>1</sup> Arris and Gale lecture (Feb. 21st, 1934), THE LANCET, 1934, i., 416; Hunterian lecture (Feb. 9th, 1935), *Ibid.*, 1935, i., 313 and 463.

and ending in death. I have produced, as well, evidence not only of the severity of the operation for removal of this tooth, when buried or impacted, but also of the gravity of the post-operative complications, which range from ununited fracture of the jaw to fatal septicæmia.

It became obvious that a great deal of unnecessary suffering would be saved if a prophylactic measure could be devised to eliminate the risks attendant upon mal-eruption. A critical study of a large mass of osteological material, correlated with the radiograms of children and young animals arranged in growth series, made it plain that probable impaction of the lower wisdom tooth could be assessed with great accuracy from 9 to 11 years of age, and that the removal of the whole dental follicle with the embryonic tooth, if it could be accomplished satisfactorily, would be a desirable prophylactic operation. So far as I can trace I am the first person to attempt this operation, the simplicity of which I announced in my former lecture (Feb. 21st, 1934), when I showed a slide of the technique. I hope to publish the

FIG. 3.—Skiagram of the same patient as Fig. 2 a year and 10 months after operation, showing obliteration of the dental crypt by ossification.

operative details in due course, but surgical colleagues who have seen it have urged me to make this preliminary announcement now that I have completed 70 cases.

The operation is exceptionally free from trauma if made early enough. The small wound inside the mouth heals by first intention and the children leave the ward on the following day. This contrasts most favourably with the trauma and long convalescence involved in operating on the fully developed misplaced tooth (Fig. 1). The operation is, however, essentially one of surgery rather than of dentistry. Fig. 2 reproduces a skiagram showing a suitable case in a child of 9½ years. The crown of the wisdom is beginning to calcify in such an oblique angle that normal eruption could not be expected. The third skiagram (Fig. 3) shows the same case 22 months after operation. Obliteration of the dental crypt has proceeded satisfactorily. The molars in front have not been injured or disturbed.

I am, Sir, yours faithfully,

London, W., March 30th.

C. BOWDLER HENRY.

## MENTAL HYGIENE IN MENTAL HOSPITALS

To the Editor of THE LANCET

SIR,—We would suggest that, as an elementary axiom of asylum hygiene, every medical officer should be compelled to spend one day a week out of his hospital.

We are, Sir, yours faithfully,  
April 13th. FOUR ASYLUM PSYCHIATRISTS.

## MANDELIC ACID IN THE TREATMENT OF URINARY INFECTIONS

To the Editor of THE LANCET

SIR,—The interesting article of Drs. Holling and Platt in your issue of April 4th adds to the accumulating evidence that in mandelic acid we have a really valuable means of attack on *B. coli* urinary infections, both in the acute and the chronic stages. A proportion of the cases of acute pyelitis treated by the older methods were permanently cured, but many became chronic. The real test of mandelic acid treatment will be the duration of its sterilising effect after cessation of treatment. Relapses undoubtedly occur, but they appear to respond well to a second course of treatment. Even if treatment had to be resumed for a week or more every few months, the result would still be a godsend to many sufferers from chronic pyelitis. Drs. Holling and Platt suggest that in cases which tend to relapse, two consecutive days of treatment should be given every month. They also emphasise the careful regulation of the bowels, both constipation and the over-use of purgatives being avoided. My impression is that even during the course of treatment a period of constipation increases the turbidity of the urine. The treatment appears to increase the constipation from which most of these patients suffer, and it is sometimes necessary to order, or increase the dose of, aperient during treatment. I find a paraffin emulsion with phenolphthalein very effective.

The appearance of finely granular casts does not seem to be any contra-indication to continuing the treatment. I have never found it accompanied by albuminuria or oliguria, and the casts are frequently absent from the next specimen of urine which is examined, even though the administration of mandelic acid is continued. Moreover, as Holling and Platt point out, the treatment apparently has no deleterious effect in cases of nephritis or nephrosis.

In a series of 26 cases, most of which were under the care of Mr. E. W. Riches at the Middlesex Hospital, I have found so great a variation in the amount of ammonium chloride required to keep the pH of the urine between 5.0 and 5.3, both in different patients and during the course of treatment of a single patient, that I doubt whether any combination of mandelic acid or its salts with the non-specific acidifying agent will prove entirely satisfactory. While 6 or 8 grammes of ammonium chloride is the usual daily dose required, I have had one patient for whom 1.5 g. was sufficient, and others who required 10 or 12 g. One patient's requirements varied from 4 to 12 g. during the course of treatment. Of Holling and Platt's three adult cases treated with ammonium mandelate, in only one was the recommended dose of mandelic acid (12 g. a day, or four doses of 51 grains of ammonium mandelate) given with no additions. In order to obtain the correct pH in the other cases, in one the dose of mandelic acid was reduced below the amount recommended, and in the other ammonium chloride had to be added. The tendency of ammonium chloride to produce anorexia, indigestion, nausea,

and occasionally vomiting, is certainly a grave disadvantage in a few cases, though I have never had to stop treatment on this account. If the claims made for Gelamon are not exaggerated, this preparation of ammonium chloride may solve the problem. It is swallowed in the form of tablets which swell up into a gelatinous mass in the stomach; this is slowly dissolved and absorbed without giving rise to any disturbance of gastric function.

The method of estimating the pH by methyl-red is a very rough one, though the good results obtained by Holling and Platt suggest that accuracy in this respect is not of great importance. Personally I use the B.D.H. Capillator, which takes very little longer.

Cases of uncomplicated *B. coli* infection are undoubtedly the most favourable. In my series there have been five in which other organisms were present (on more than a single occasion) in addition to *B. coli*; no anatomical abnormality of the urinary tract was discoverable. The results were as follows:—

Case.	Secondary organism.	Sterilised to <i>B. coli</i> .	Sterilised to other organism.	Symptomatic result.
1	<i>Staph. albus.</i>	Yes.	No.	Improved.
2	"	Yes.	No.	Not much improved.
3	"	Yes.	No.	"
4	"	Yes.	Yes.	"
5	Streptococcus.	Yes.	Yes.	Improved.

I think mandelic acid should be tried in these cases, but one would be less confident of success.

Some patients—usually those whose main complaint is of pain in the loin or the iliac fossa, with or without frequency of micturition—are unrelieved as regards the pain in spite of sterilisation of the urine; in these cases the pain may be due to spasticity in some part of the musculature of the upper urinary tract.

Another type of case in which the treatment has been tried is that of massive infections with much pus in the urine, such as occasionally occur after pyelolithotomy or prostatectomy in previously infected cases. There is usually a mixed infection, often with *B. proteus*, the urine is very alkaline, and the pH cannot be lowered below 5.8 or 6.0, even with 12 g. of ammonium chloride daily. These cases are only slightly, if at all, benefited by the treatment.

I am, Sir, yours faithfully,  
London, W., April 11th. ALAN W. CUBITT.

## VITAMIN B<sub>1</sub> BY INJECTION IN THE TREATMENT OF NERVOUS DISEASES

To the Editor of THE LANCET

SIR,—Dr. Leak criticises me for going to a continental firm for supplies of vitamin B<sub>1</sub> when British firms are able and willing to provide experimental products. The facts are not, however, as Dr. Leak imagines. My first observations were made with a preparation made by British Drug Houses containing 100 international units in 2 c.cm. Their supplies were quickly exhausted, and further I knew of no firm who could supply the vitamin in a more concentrated form except Hoffmann-La Roche, who have provided me, free of charge, with a large number of ampoules containing 400 international units in 1 c.cm. for clinical trial. It is not surprising, therefore, that I feel indebted to them for making my investigations possible. The British

Drug Houses' preparation is now again available, and I can testify to its efficacy though I prefer the more concentrated solution prepared by Hoffmann-La Roche.

I was much interested in Dr. Leak's account of his investigations, but deplore his desire to introduce politics into the realm of research!

I am, Sir, yours faithfully,

Edinburgh, April 9th.

W. RITCHIE RUSSELL.

### ANNIVERSARY OF A REFORM

To the Editor of THE LANCET

SIR,—On April 23rd and 24th the Association for Moral and Social Hygiene is celebrating an historic anniversary: the jubilee of the repeal of the Contagious Diseases Acts in 1886. To many people to-day the words "Contagious Diseases Acts" may have no significance at all, yet these Acts were the cause of a successful agitation which lasted 16 years, and had remarkable results throughout the world. Moreover the " repealers," led by Josephine Butler, presented a challenge to contemporary ideas on the social evil of prostitution which has largely changed the thought of the Western world in regard to it and is now affecting the East as well.

The British example has since been followed in the Dominions and Colonies, and by Norway, Denmark, Finland, Holland, United States, Czechoslovakia, Bolivia, Palestine, U.S.S.R., Germany, and Switzerland. (Germany under the present régime has since reintroduced the old system in certain towns.)

Great Britain never had the full continental system of registered women and licensed houses, but it made a beginning between 1864-69 with the C.D. Acts and introduced the "registered prostitute," under special police control and regular medical inspection, for use of the Army and Navy in certain garrison towns. The object was to reduce venereal

diseases in the Services but the results were nil. We now know that such medical examination of one sex only for the benefit of the other does not protect the other; but it was not known then, or not generally accepted, by the medical profession and the officials. A certain small number of doctors and administrators did criticise the Acts for medical reasons, but the deep and passionate revolt against them came from men and women who opposed them not only on moral grounds but primarily on grounds of the gross violation of the principles of law and justice involved in the Acts. Mrs. Butler warned the people of this country:

"Never forget that if we allow persons belonging to any class of the citizens to be enslaved—however obscure, despised or degraded that class may be—these will not long continue to be the only slaves. The principle of individual liberty, once infringed, will be gradually lost."

The agitation was eventually successful and it brought not only repeal of the Acts but sweeping changes of the English law in regard to sex morals. Moreover, it led to improvements in the Service conditions which have brought venereal diseases down from 267 cases per 1000 men in 1886 to 10 per 1000 in 1933. These and many other changes for the better we celebrate on April 23rd and 24th. Lady Astor, Prof. Gilbert Murray, and two descendants of Josephine Butler, Mr. R. A. Butler, M.P. (Under-Secretary for India), and Mr. Andrew Butler, will speak at the public luncheon at the Criterion on the 23rd, which will be followed by a service of thanksgiving at St. Martin-in-the-Fields at 6 p.m. at which the Bishop of Liverpool will preach a special sermon. Tickets and further particulars of the meeting on the 24th can be obtained at this office.

I am, Sir, yours faithfully,

ALISON NEILANS,

Secretary, Association for Moral and Social Hygiene.

Livingstone House, Westminster, S.W., April 7th.

## PARLIAMENTARY INTELLIGENCE

### NOTES ON CURRENT TOPICS

#### Easter Adjournment

BOTH Houses of Parliament adjourned on Thursday, April 9th, for the Easter recess. The House of Lords will reassemble on April 28th and the House of Commons on April 21st. On the latter date the Chancellor of the Exchequer will open his Budget.

#### Magistrates and Birching of Children

In the House of Commons on April 7th Mr. PARKER moved that leave be given to bring in a Bill to abolish the power of a court of summary jurisdiction to order a child to be whipped. He said that it had been suggested that when children mutilated animals birching was a desirable punishment. It was not. If serious cases of that kind were brought up birching was not the right punishment. Where a child committed a crime of that sort he should be subjected to some sort of treatment so that he would not do it again. The child should be examined medically, and if necessary be sent to a Home Office school and treated. There had been a very big decline in the number of birchings. In 1913 the number was 2079, in 1930 it was 130, and in 1933 it was 151. Birching had declined largely because magistrates had not found it effective. Unfortunately children were treated very differently in various parts of the country. There had been a very big decrease in juvenile crime from the war down to 1930. Between 1917 and 1929 the number of juvenile convictions decreased from 27,290 to 5936. There had been an increase of convictions since that day, and to his

mind that increase had been due to widespread unemployment among juveniles of 14 to 21. An unfortunate example had been set to younger children. The right way to secure a decrease in that crime was partly by raising the school leaving age, partly by providing better recreation facilities for children and young persons over 14, especially in the way of clubs, playing fields, and so on, and partly by placing new industries in the depressed areas.

Leave to bring in the Bill was refused by 166 votes to 119.

#### The Means Test

##### POSITION OF THE UNEMPLOYMENT ASSISTANCE BOARD

On the motion for the adjournment in the House of Commons on April 9th Mr. D. GRENFELL called attention to the condition of the unemployed, and in particular of those who came under the administration of the Unemployment Assistance Board. He said that the House had been informed on the previous day that there was a live register of nearly 2,000,000 persons. Nearly half that total came under the inquiry under Part 2 of the Unemployment Act. After referring to individual cases of hardship the hon. Member said that there existed a scandalous condition of affairs. The private affairs of men and women were inquired into in a way that was quite intolerable to a person of average pride. If a house showed evidence of cleanness, neatness, and of family pride, that was a disability, and those concerned received less assistance because of the good appearance of the house. People must not only be poor but also in debt before they received the attention of the officers of the Board.

Mr. FORT complained of the delay in introducing the fresh unemployment assistance regulations.—Mr. BATEY said that he would not be satisfied with the abolition of the household means test. He stood for the abolition of the family means test and the personal means test as well.

Mr. GUY said that the great justification for an inquiry into special circumstances was that some special provision might be made in cases of particular need. Everyone knew that there were cases of hardship under the present means test. There should be a distinction between the standard of assistance given in this case and that given under the poor-law. They did not want a destitution test for the able-bodied unemployed. They wanted a certain standard of living for them, so that they might be maintained as efficient units ready to take their place again in industry.

#### REPLY BY THE MINISTER OF LABOUR

Mr. ERNEST BROWN said that the problem could be simply stated, but it could not be simply solved. The trouble was that the new system was applied to thousands of towns and villages where an infinite variety of practice had previously reigned. They had to consider the effect of the regulations and to see how they could meet what fair-minded people would regard as genuine hardships. Those investigations were almost at an end, and what the Government put in their election manifesto they meant to carry out. The House would not have long to wait. His own impression was that the local area officers were doing their work extraordinarily well, with a great understanding of the circumstances of those who came to them, with great sympathy, and with a desire to do what the Act intended—namely, to make the new system a more humane means of dealing with the able-bodied unemployed. It was easy to urge the abolition of the means test and to bring forward hard cases. He had been surprised in the last nine months, not at the number of hard cases, but rather at the smallness of the number. They had to face the issue whether they ought to give public assistance without consideration of the question of means. There were two points—was there to be a test at all? and what kind of test was it to be? There had been many investigations into the question of whether or not there could be another test of need, and with one exception each investigation had come to the conclusion that if there was to be a test of need regarding applicants for public funds it must be in terms of the household. Whereas some local authorities administered State funds with the same care as that with which they administered their own ratepayers' money, there was another class of local authority that did not. The Government would do their best, and that very soon, to bring before the House improved arrangements for administering a uniform system with due regard to local opinion over the whole of Great Britain. The investigations were nearly complete and the House would not have to wait long after Easter.

### HOUSE OF COMMONS

TUESDAY, APRIL 7TH

#### Poison Gas in Warfare

Mr. CARY asked the Secretary of State for War what type of training, if any, was carried out by the War Office in the use of poison gas as a legitimate weapon of warfare; and if chemical experts were employed to work to this end in consultation with Army authorities.—Mr. DUFF COOPER replied: No training in the use of poison gas as a weapon of war is carried out in the Army, but possible methods of the use of gas have naturally to be studied in connexion with training in defence against gas. Chemical experts have, of course, been closely associated with Army authorities in connexion with such training.

Mr. SHINWELL asked the Secretary of State for War the names and basis of the gases with which the anti-gas protectors for the troops had been recently tested; and whether the results had been proved effective.—

Mr. DUFF COOPER replied: As I informed the hon. Member in reply to a question on 31st March last, the present pattern of mobilisation container is considered to provide adequate protection against the gases likely to be encountered. The hon. Member will doubtless realise that it is not in the public interest that I should answer the first part of his question.

Mr. SHINWELL asked the Secretary of State for War whether any protective clothing other than oilskins were in issue for the protection of the troops from corrosive and incendiary chemicals; whether he was aware that the German and other governments were now experimenting with rubber clothing.—Mr. DUFF COOPER replied: The answer to the first part of the question is in the negative, and to the second in the affirmative.

Mr. KIRKWOOD asked the Home Secretary whether the ability of infants and young children to breathe normally, if at all, in a gas mask had been satisfactorily established; whether the period of time was known that must elapse before gas lost its harmful effects when the populace could emerge from cover with safety; what was the penetrating quality of gas; was it capable of reaching those taking cover at, say, the underground railway level; and what action the Government proposed to take to prevent food and water, both under cover and otherwise, becoming contaminated by gas.—Mr. G. LLOYD replied: The question of the protection of infants and young persons is receiving attention and various alternative methods of protection are under investigation. The period of time during which poison gas continues to exercise its harmful effects depends upon a number of factors, such as the nature of the gas employed, the quantity liberated, and the meteorological conditions prevailing at the time. The instructions to be issued to the public will give advice as to when it is safe to emerge from cover. When poison gas is liberated it mixes with the air in the vicinity. This leads to a progressive dilution of the gas cloud which tends to follow the path of the normal air currents existing at the time. The question whether gas could reach the tube railways would depend upon the protective measures adopted in connexion with the supply of air to the railway. Consideration has already been given to this question. The Government have considered the action necessary to prevent food and water becoming contaminated by gas. Protective measures are quite practicable and will be embodied in the instructions to be issued to the public.

Sir GIFFORD FOX asked the Home Secretary whether he was yet in a position to make a statement about the supply of anti-gas respirators to the civilian population in case of air attack.—Mr. G. LLOYD, Under-Secretary, Home Office, replied: Yes, Sir. A simple but effective form of respirator, for use by the civil population, has been devised and the final design is now being settled. The Government propose to accumulate sufficient stocks of this respirator to enable issue to be made to all persons in areas exposed to danger in the event of air attack. The issue would be made free of charge. In the event of attack from the air everyone would be advised to remain indoors in a gas-proofed room in order to avoid danger of contamination; and the respirators for the use of the civil population would primarily be of service for the purpose of enabling people who were out of doors when a raid occurred, or whose gas-proofed rooms had been damaged, to get to a place of safety. The Government are fully alive to the need for providing for the needs of young children and babies, and special methods of protection are being developed for this purpose. It may be anticipated that many factories in this country will seek to put on the market respirators of their own design, and the Government have devised a scheme, the details of which are about to be published, by which manufacturers who make approved types of respirators and who accept various conditions, including liability to Government inspection, will be licensed to affix a Home Office certification mark to their respirators. Purchasers will be well advised not to regard respirators as satisfactory unless they bear this mark.

#### New Cost-of-Living Index Number

Mr. BOOTHBY asked the Minister of Labour whether he proposed to revise the basis of the cost-of-living index number.—Mr. E. BROWN replied: Yes, Sir, I have recently

given further consideration to this matter and have decided that a revision of the basis of the cost-of-living index number should now be undertaken. For this purpose, it will be necessary to collect data with regard to the distribution of the main items of expenditure of working-class households at the present time. An inquiry of this character, on a scale sufficiently comprehensive to provide representative information covering different seasons of the year, cannot be completed before the end of next year. In the meantime, the cost-of-living index number will continue to be calculated on the existing basis, and I anticipate that the new index number can be so linked on to the previous numbers as to continue the series without a break. I should add that as regards the methods to be adopted in the conduct of the inquiry, I hope to have the assistance of a small advisory committee which will include representatives of employers and trade unions.

WEDNESDAY, APRIL 8TH

### Danger Spots and Road Accidents

Mr. ANSTRUTHER-GRAY asked the Minister of Transport if he could state from statistics of the last two years which were the three most dangerous spots in London, rural Scotland, and Glasgow, and the number of accidents that had occurred at each during that period.—Mr. HORE-BELISHA replied: The following statement shows certain streets in London and Glasgow in which road accidents involving personal injury have been particularly numerous. Information regarding accidents in the rural areas of Scotland cannot readily be given in this form:—

LONDON—	Six months ended Sept. 30th—	
	1934.	1935.
Sections of Commercial-road and East India Dock-road .. .. .	236	251
Lewisham High-road and Eltham-road .. .. .	158	155
Chiswick High-road and King-street .. .. .	194	121
GLASGOW—		
Dumbarton-road from Church-street to Balshagray-avenue .. .. .	121	128
Paisley-road and Paisley-road West, from Morrison-street to Lorne-street .. .. .	92	97
Garscube-road, from Burnside-street to Possil-road .. .. .	47	61

Sir ALFRED BEIT asked the Minister of Transport whether he would arrange for fuller publicity to be given

regarding the ages and physical defects, if any, of the victims of road accidents.—Mr. HORE-BELISHA replied: Yes, Sir. The ages of persons killed and any physical defects from which they suffered, so far as they were considered to have been a cause of the accidents, will be shown in the Report on Fatal Accidents on the roads during 1935, which will be issued shortly. Similar particulars will be available in the reports on road accidents involving personal injury which are being obtained from the beginning of this month.

Captain STRICKLAND asked the Minister of Transport whether he had observed the reports of accidents to children cycling in the streets; and whether, when legislation was being introduced, he would consider fixing a minimum age for persons using bicycles, as was the case with motor cyclists.—Mr. HORE-BELISHA replied: Yes, Sir. The figures before me are alarming and show that nearly 40 per cent. of the cyclists killed in road accidents are under 21 years of age.

### Out-patient Clinics for Mental Treatment

Mr. SORENSEN asked the Minister of Health the number of out-patient clinics for mental patients that had been established to the present date.—Mr. SHAKESPEARE replied: The latest available information indicates that there are now 143 out-patient clinics associated with public mental hospitals. More comprehensive particulars will be secured by a questionnaire which is shortly to be issued to local authorities by the Board of Control.

THURSDAY, APRIL 9TH

### Maternity and Child Welfare

Mr. EDWARD WILLIAMS asked the Minister of Health whether he had been in touch with the British Medical Association with regard to maternity services; and, in view of their contention that a unified public health service was the most sure means of reducing maternal and infant mortality, what action he proposed to take in this matter.—Sir KINGSLEY WOOD replied: Yes, Sir. I have recently received a deputation from the Association on this subject. I stated that I should give further consideration to their proposals after I had received the report of my medical officers who are making special investigations in the areas in which the maternal mortality-rate is high.

## PUBLIC HEALTH

### Public-school Boys Learn About Public Health

ON the joint invitation of Sir Kingsley Wood, Minister of Health, and of Mr. Herbert Morrison, leader of the London County Council, a party of public-school boys and masters, 25 of each, spent three days in studying the problems of local administration in London. The qualification for admission of a boy was that he must have the school certificate and be over 17 years of age. In all 28 schools were represented. The party was welcomed by Lord Snell, chairman of the L.C.C., and then listened to an account by Mr. Morrison of the duties of the L.C.C. and how their functions are carried out by the various committees and departments. Dr. W. Allen Daley and Dr. Andrew Topping explained the work of the public health department, the former dealing with the broader aspects of hygiene. Dr. Daley told of the great epidemics of the past, of the work of the commissioners who investigated the conditions of life of the labouring classes nearly a hundred years ago, and of the rise and development of public health work. He described the environmental services, drains, sewers and sewage disposal, the collection and disposal of refuse, town-planning and building by-laws, the steps which are taken to ensure that houses are maintained in a satisfactory condition, and problems of unfit houses and clearance

areas. And so on through the provision of pure air, pure water, and pure food, and the measures to control infectious disease, to the various medical services for the individual and the steps taken to educate the public. The importance of public health work to everyone was emphasised, examples being the economic burden to the community of the care of those who are disabled by mental or physical illness and of the dependants of those who prematurely die because of preventable illness. Mention was made of the epidemic which attacks rich and poor alike, of the serious effect which disease in our ports would cause to our shipping, and of the part played by medical discoveries in reducing the death-rate.

Interest was shown by the number and nature of the questions put to the lecturer. Only ten minutes had been allotted to questions, yet more than twice that time had to be given before the closure could be applied in order that the next item on the programme could proceed. Questions came almost entirely from the boys, the masters being interested to observe the first reactions of the boys to an address of this character. The first was an invitation to say what the next big development in public health work was likely to be. The answer hazarded in reply was that it might be a reorganisation of medical benefit as now provided under the National Health Insurance Acts so as to provide consultant and pathological services for insured persons and a medical

service for the dependants of the insured. The next questioner asked for a detailed description of the various grades of milk and, as a supplementary, an opinion on the nutritive value of pasteurised as compared with raw milk. Then came a question familiar to all lecturers on public health: what was the answer to the contention that modern hygiene was preserving the lives of the inefficient and the degenerate. From this it was an easy stage to a question what was being done for the mentally defective and what could be done to prevent the births of more mentally defectives; then euthanasia was raised and what doctors thought of it. Questions followed as to how the medical needs of the non-insured casual employed were provided, and what the L.C.C. was doing for the sleeper on the Embankment. Finally the lecturer's attention was invited to those just above the National Health Insurance level: what about the "black-coated worker" who had lost his job and who needed an operation?

In the afternoon the party divided into two groups and visited St. James's and St. Giles's Hospitals. On their return Dr. Topping addressed them on problems of hospital organisation and administration, after which he, too, was subjected to a barrage of questions. Dr. Topping referred to the provision made for the sick by the religious orders and the development from that of the great voluntary hospitals. He traced the provision made by the guardians of the poor for the destitute sick and showed that since 1929, when the old poor-law system was abolished and the work transferred to the councils, the hospitals were preparing to undertake every kind of medical treatment, particularly where, as in London, they had been "appropriated" from the poor-law and were now administered under the Public Health Acts. The two succeeding days were devoted to education and housing. The party

was addressed by the valuer and the architect of the L.C.C., by a district inspector, and one of the assistant education officers. Visits were paid to various types of schools, to cottage housing estates, and slum clearance schemes.

### INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 4TH, 1936

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2232; diphtheria, 1134; enteric fever, 16; pneumonia (primary or influenzal), 1119; puerperal fever, 41; puerperal pyrexia, 121; cerebro-spinal fever, 27; acute poliomyelitis, 5; acute polio-encephalitis, 2; encephalitis lethargica, 8; dysentery, 27; ophthalmia neonatorum, 87. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 10th was 6778, which included: Scarlet fever, 999; diphtheria, 1112; measles, 3284; whooping-cough, 648; puerperal fever, 14 mothers (plus 9 babies); encephalitis lethargica, 282; poliomyelitis, 5. At St. Margaret's Hospital there were 29 babies (plus 11 mothers) with ophthalmia neonatorum.

*Deaths.*—In 121 great towns, including London, there was no death from small-pox, 3 (2) from enteric fever, 81 (24) from measles, 10 (2) from scarlet fever, 32 (5) from whooping-cough, 29 (3) from diphtheria, 44 (15) from diarrhoea and enteritis under two years, and 71 (15) from influenza. The figures in parentheses are those for London itself.

The mortality from measles is still falling, the figures for the last eight weeks (working backwards) being 81, 104, 114, 105, 84, 88, 78, 58 for the country as a whole, and 24, 33, 62, 58, 47, 38, 18, 14 for Greater London. Liverpool reported 7 deaths, Sheffield 6, Manchester 4, Gateshead 3, no other great town more than 2. Leeds reported 3 fatal cases of scarlet fever, Birmingham 3 of whooping-cough. Deaths from diphtheria were reported from 19 great towns, 3 each from Manchester and Sheffield.

The number of stillbirths notified during the week was 320 (corresponding to a rate of 49 per 1000 total births), including 49 in London.

## MEDICAL NEWS

### Royal College of Surgeons of England

A quarterly meeting of the council was held on April 6th, with Sir Cuthbert Wallace, the president, in the chair. The Jacksonian prize for 1935 was awarded to Mr. R. C. Brock, F.R.C.S., of Guy's Hospital, for his dissertation in the pathology, diagnosis, and treatment of intra-thoracic new growths, including neoplasms of the oesophagus, and a certificate of honourable mention and an honorarium of ten guineas was awarded to Mr. H. P. Nelson, F.R.C.S., of St. Bartholomew's Hospital. The subject for the Jacksonian prize for 1937 will be the pathology, diagnosis, and treatment of tumours of the pituitary gland.

The Walker prize for 1931-35 was awarded to Prof. E. L. Kennaway, M.D., F.R.S., of the Cancer Hospital, London, in recognition of the inspiration and direction he has given to investigations leading to the discovery of a pure chemical compound by which either carcinoma or sarcoma can be induced. The John Tomes prize for 1933-35 was awarded to Mr. Alfred William Wellings, M.D.S., for his original work on dental histology. The Cartwright medal for 1931-35 was awarded to Mr. Arthur Bulleid, M.R.C.S., L.D.S., of Guy's Hospital, for his essay on the relationship of pulpless teeth to general disease and their treatment, with special reference to periapical rarefaction. It was decided that the subject of the Cartwright prize for the years 1936-40 should be general and local diseases as factors in the causation of pathological oral conditions.

Reginald Seymour Lawrie, of Middlesex Hospital, was appointed Begley student for the ensuing three years. The president reported that he had appointed Mr. Sydney Scott as representative of the College at the International Congress of Laryngology, Rhinology, and Otology, to be

held in Berlin in August, 1936. At the request of the director-general of the Indian Medical Service it was decided, subject to satisfactory arrangements being made, to hold a primary fellowship examination in India at the end of 1937.

Mr. H. L. Eason, vice-chancellor of the University of London, and Dr. Egbert Morland, assistant editor of THE LANCET, were elected fellows of the College under the charter which permits the council to elect annually to the fellowship without examination two members of twenty years' standing. A diploma of membership was granted to James Firth Heslop, of Manchester University.

Diplomas in child health were granted jointly with the Royal College of Physicians to the following candidates:—

Cécile H. D. Asher, L. I. S. Campbell, E. H. Capel, Meyer Carr, Anne A. Craig, R. H. Fish, Margaret L. Foxwell, S. C. Gawne, Constance M. Hall, Irene M. Holoran, A. H. Khan, Hah-Liong Lee, B. F. Longbotham, W. H. Patterson, Margaret R. Price, C. K. Rowan-Legge, W. I. D. Scott, J. M. Watt, and R. A. Wilson.

### International Society of Medical Hydrology

The annual meeting of this society is to be held this year in Austria, from Oct. 10th to 16th. The opening ceremonies and the first medical discussion will take place in Innsbruck; the party will then proceed to Badgastein and Hofgastein, and go from there to Salzburg. After the meeting visits may be paid to the Salzkammergut and also to Vienna and Budapest. The two principal subjects for consideration are the spa treatment of disorders of old age, to be introduced by Sir Humphry Rolleston, and radio-activity in medicinal waters. A party will be formed to travel from London on Oct. 9th and non-members of the society may attend the meeting on payment of a small fee. Further particulars may be obtained from the general secretary at 109, Kingsway, London, W.C.2.

**University of London**

At the London School of Hygiene (Keppel-street, W.C.), at 5.30 p.m. on May 5th, 7th, and 8th, Prof. A. Butenandt, of the institute of organic chemistry at Danzig, will lecture on the biochemistry of the sterol group.—Mr. H. M. Traquair, ophthalmic surgeon to the Edinburgh Royal Infirmary, will give his (postponed) lectures on perimetry on May 18th and 19th at 5.30 p.m. at University College Hospital medical school.—On May 12th, 13th, and 14th, at 5.30 p.m., at the College of the Pharmaceutical Society (17, Bloomsbury-square, W.C.), Prof. Arthur Stoll, of Basle, will speak on cardiac glucosides.—On May 15th, at 5 p.m., at King's College, Strand, Dr. Henri Fredericq, professor of physiology in the University of Liège, will give a lecture on the laws of excitation of the autonomic nervous systems with reference to chemical mediators.—On May 21st Dr. Alfred Adler, of Vienna, will lecture on some developments in individual psychology; the meeting will be at University College at 5.30 p.m.—On May 7th and 8th, at 5.30 p.m., at the Royal Veterinary College, two lectures on mineral deficiency diseases of farm animals will be given by Prof. Henry Dryerre and Mr. J. Russell Greig, Ph.D.—Admission to the lectures is free, without ticket.

**University of Adelaide**

The South Australian Government has appointed Dr. E. Weston Hurst to be director of the new Institute of Medical Science which is being established in Adelaide.

Dr. Hurst, who is 35 years of age, graduated at Birmingham in 1922. He obtained the degree of M.D. two years later and of D.Sc. in 1932, when he also became M.R.C.P. Lond. In 1923-24 he was the Walter Myers travelling student of Birmingham University and he worked at the National Hospital, Queen-square, until in 1926 he was appointed pathologist to the Miller General Hospital, Greenwich. In 1928, for the Milbank Fund, he began investigations into poliomyelitis, and from that time he has been on the staff of the Lister Institute, holding the university appointment of reader in experimental pathology. From 1932-34 he was given leave of absence to work at the Rockefeller Institute at Princeton, New Jersey. His William Withering lectures, delivered at Birmingham and published in THE LANCET last September, formed an authoritative review of the neurotropic virus diseases, and his views on this subject are further expanded in the current issue of *Brain*. His own work includes original observations on the viruses of poliomyelitis and rabies.

**Royal Faculty of Physicians and Surgeons of Glasgow**

At a meeting of the Faculty, held on April 6th, with Prof. Archibald Young, the president, in the chair, the following were admitted to the fellowship:—

Edmund Denis Cooper, Thomas Neilson Fraser, Robert Sinclair Kerr, James Anthony Waring McCluskie, William John Brownlow Riddell, and Laurance David Wellwood Scott (Glasgow), Susilananda Sen (London), and Edgar William Thomas (Rhonda).

**Royal College of Surgeons of Edinburgh**

At recent examinations of the College the following candidates were successful:—

**FINAL EXAMINATION FOR L.D.S.**

Robert Lawrie, D. L. Mackenzie, Annie McA. Douglas, L. A. P. Cantin, H. R. Inglis, Elsbeth Grunberg, E. O. Rossetti, Mary D. Shepherd, Kurt Bronne, Werner Sachs, and James Hughes.

**Indian Medical Service**

The annual dinner will be held at the Trocadero Restaurant, London, on Wednesday, June 17th, at 7.15 p.m., when Major-General Sir Robert McCarrison, C.I.E., will preside. Officers can arrange to sit near their friends, as separate tables to seat eight will be provided. Tickets from the joint hon. secretary, Sir Thomas Carey Evans, Hammersmith Hospital, Ducañe-road, London, W.12.

**Hunterian Society**

At the annual general meeting of this society held on April 9th, the following office-bearers were elected:—

President: Mr. H. L. Attwater; vice-presidents: Dr. W. Brander, Dr. A. Westerman, Mr. M. Oldershaw, and Dr. W. H. F. Oxley; hon. treasurer: Dr. Irwin Moore; trustees: Sir Bruce Bruce-Porter and Dr. A. P. Gibbons; orator: Lord Horder; hon. secretaries: Mr. A. E. Porritt and Dr. John Leobody; members of the Council: Dr. Thomson Brown, Dr. S. Monckton Copeman, Dr. W. S. C. Copeman, Dr. G. R. Mather Cordiner, Dr. John Eyre, Dr. F. Howard Humphris, Dr. B. H. Jones, Dr. E. W. McCormick, Dr. W. Mailer, Dr. D. O. Norris, Dr. Basil Parsons-Smith, and Dr. A. Wilson; hon. librarian: Mr. A. E. Mortimer Woolf; auditors: Dr. Ernest Young and Mr. Andrew McAllister.

Prof. Grey Turner has been elected a corresponding member of the Surgical Society of Vienna.

**King Edward's Hospital Fund for London**

The King has signified his intention to give an annual subscription of £1000 to this Fund.

**St. John Ambulance Brigade**

The chief commissioner of the Brigade announces that he has appointed Dr. William C. Bental to be his staff officer for air-raid precautions.

**International Pædiatric Congress**

This congress, which was to be held in Rome in September, has been postponed until the spring of next year.

**Lectures on Nutrition**

On April 21st, 22nd, 23rd, and 24th, at 6 p.m., Dr. J. Alison Glover will lecture at Gresham College, Basinghall-street, London, E.C. His subject is Some Aspects of Nutrition, and the lectures are open to all without charge.

**West End Hospital for Nervous Diseases**

A Savill prize is offered for the best thesis on a neurological subject submitted by a candidate who has attended the practice of this hospital on at least ten occasions. The subject chosen for the thesis should be submitted to the examiners not later than May 31st, and the thesis itself by Nov. 30th. Further information may be had from the secretary of the hospital, Welbeck-street, London, W.1.

**Bayliss-Starling Scholarship**

An award of this scholarship, which is of an annual value of £120, will shortly be made. The scholar will be required to follow a course at University College in the principle and methods of research in physiology and biochemistry. Further information is obtainable from the secretary of the college, Gower-street, London, W.C.1.

**British Institute of Philosophy**

The Wright memorial lecture, on the Romantic Factor in Modern Politics will be delivered by Prof. Ernest Barker at University College, Gower-street, London, W.C., at 5.45 p.m. on Thursday, May 7th. Cards of admission can be obtained from the director of studies at University Hall, 14, Gordon-square, London, W.C.1.

**A Congress of Cardiologists**

We are informed that a meeting of specialists in cardiology will be held at Royat over Whitsuntide (May 31st to June 1st), when the subject of discussion will be Vascular Spasm. British members of the foreign committee include Sir Thomas Lewis, F.R.S., Sir Farquhar Buzzard, Sir Walter Langdon-Brown, Sir Maurice Cassidy, Sir StClair Thomson, Dr. John Parkinson, Dr. F. W. Price, Dr. Basil Parsons-Smith, Dr. T. F. Cotton, Dr. Maurice Campbell, Dr. Evan Bedford, and Dr. A. P. Cawadiaz.

**North Kensington Women's Welfare Centre**

A lecture-demonstration on the theory and practice of contraception will be given at the gynaecological and birth control clinic on Thursday evening, April 30th, at 8.30 p.m. Dr. Helena Wright will be the lecturer, and a fee of 5s. is charged to meet the expenses incurred. There are daily clinic sessions at which further experience can be acquired and a fee of 1 guinea admits to two or three of these sessions as well as to the lecture-demonstration. Applications to attend the lecture and sessions should be made in advance to the secretary of the clinic, 12, Telford-road, Ladbroke-grove, W.10.

**Rowett Research Institute**

Dr. J. T. Irving has been appointed head of the physiology department of this institute, near Aberdeen, in succession to Dr. R. C. Garry who has become professor of physiology at St. Andrews.

Dr. Irving was born in Christchurch, New Zealand, and educated at Christ's College there. He came to England in 1920 as a student at Caius College, Cambridge, and was placed in the first class in both parts of the natural sciences tripos. From 1924 to 1928 he was engaged on research in biochemistry being awarded a Beit fellowship at Oxford during the last two of these years. In 1927 he received the degree of Ph.D. at Cambridge and in the following year he entered Guy's Hospital, London, to complete his medical studies. Since qualification in 1931 he has been lecturer in physiology at Bristol and Leeds. His investigations have been chiefly concerned with carbohydrate metabolism and with abdominal sensation.

## PHYSICAL EDUCATION

THE report of the Physical Education Committee of the British Medical Association, published to-day by the Association and obtainable for the modest price of 6d., makes many important suggestions for the improvement of the physical efficiency of the nation. The Committee was appointed early in 1935 "to consider and report upon the necessity for the cultivation of the physical development of the civilian population and the methods to be pursued for this object." It consisted of 22 members, including the following 15 doctors: Dr. E. Kaye Le Fleming, Dr. S. Watson Smith, Mr. H. S. Souttar, Mr. N. Bishop Harman, Sir Henry Brackenbury, Mr. W. McAdam Eccles, Sir Crisp English, Dr. W. N. West-Watson, Dr. Adolphe Abrahams, Dame Janet Campbell, Dr. G. P. Crowden, Dr. Henry Herd, Dr. L. R. Lemprière, Mr. R. C. Elmslie, and Miss M. Forrester-Brown.

The Committee has received evidence from numerous expert witnesses and has circulated four different questionnaires which have been completed by schools, colleges, voluntary organisations and industrial firms, and representatives of foreign countries.

The report begins with a discussion of the importance of exercise, fresh air, sunshine, diet, clothing, and so forth in the maintenance of bodily fitness. This is followed by a survey of the position of physical education in the general educational system. The Committee finds that the existing arrangements in schools leave much to be desired. Usually too little time is devoted to the subject, and many schools possess neither suitable accommodation for gymnastic training nor sufficient playing field space for outdoor games.

It recommends that properly equipped gymnasias, together with changing rooms and shower baths, should be provided in senior elementary, central, and junior technical schools, and that facilities for games and swimming should be greatly increased. The importance of physical exercises being performed in appropriate costume is emphasised and local education authorities are urged to supply a stock of suitable clothing and gymnastic shoes for children who cannot provide their own. The appointment of expert organisers of physical education by all education authorities is strongly recommended and suggestions are made as to the numbers of organisers of both sexes required for different school populations.

The Committee deprecates the tendency, especially evident in many public schools for boys, to subordinate physical education in gymnasias to field games and athletics, and "to regard games as an unduly serious business rather than to play them for the pleasure of playing." It also condemns the practice, common in public and secondary schools, of curtailing the physical activities of senior pupils who are preparing for examinations. Instruction in elementary physiology and hygiene is considered to be an essential part of physical education and it is recommended that such instruction should be given in all schools as a branch of general science.

The provision made for the promotion of physical fitness among persons no longer attending school was found on investigation to be seriously inadequate. Despite the valuable contributions of local authorities, voluntary organisations, and business firms to the bodily well-being of this section of the population, it appears that at least 40 per cent. of persons between the ages of 14 and 40 take no part in organised physical

recreation. It is recommended that the existing facilities should be greatly extended and that, as one means to this end, there should be closer coöperation between all organisations concerned with the physical welfare of the community. Hope is expressed that the recently established Central Council of Recreative Physical Training may act as an authoritative coördinating body, uniting in a common policy the endeavours of the Board of Education and the voluntary organisations.

The training of teachers of physical education is next discussed, and here the need is stressed for a greatly increased supply of men suitably trained to teach the subject in public and secondary schools for boys. The comparative neglect of physical education in the university training departments for teachers is deplored, and it is recommended that universities should not only provide for the physical education of undergraduates but should also establish an internal diploma in the subject.

### Medical Supervision of Physical Education

Finally, the Committee envisages a much closer relation between physical education and the science and art of medicine. The recommendations (LV. to LXV.) arising from this aspect of their deliberations are set out in full below.

#### IN SCHOOLS

There should be close coöperation between the head master (or mistress), the school doctor, the parents, the gymnastic teacher, and the general teaching staff in all matters pertaining to the physical welfare of the individual pupil.

Such coöperation is especially desirable in the prevention of the strain which girls are liable to suffer in mixed schools.

Adequate medical supervision should be available to ensure that unfit children do not participate in unsuitable or excessive exercises or games and that undernourished children receive sufficient supplementary feeding to enable them to participate with benefit in the regular physical exercises undertaken by the other children.

#### IN VOLUNTARY ORGANISATIONS

There should be closer coöperation between the health services and the educational services, whether central or local, in relation to the physical education of the population. The medical and physical training staff of the local authority should be available for consultation in connexion with "keep-fit" and other recreative classes in the area.

Leaders should be trained to watch for signs of physical disability, and should advise any member of the class who appears distressed or unduly fatigued to consult his or her doctor before resuming attendance.

Clubs should attempt to provide suitable non-technical lectures, preferably by medical men, on physiology and hygiene.

Recreative physical activities provided by industrial firms should be linked with the medical supervision of the employees.

#### IN PHYSICAL TRAINING COLLEGES

Entrants to the physical training colleges should be subjected to a thorough medical examination.

Medical examinations of students in training at the physical training colleges should be held at frequent intervals, and the work of individual students regulated in accordance with the examination results.

The medical profession should coöperate with the gymnastic profession by investigating the physiological requirements and effects of the various exercises with a view to the scientific arrangement of the syllabus of training. To facilitate such investigation, efforts should be made to establish some uniform system of physical assessment of the individual student. In particular, a standard method of testing exercise tolerance should be devised.

Post-graduate courses should be established to provide

medical men and women with the special training which the medical supervision of physical education demands.

Appendices to the report contain an interesting historical sketch of physical education through the ages, a brief outline of the position of physical education in various foreign countries, and a description of a "standards" scheme for school athletics which is suggested as an alternative to the usual school sports system.

### ROYAL MEDICAL BENEVOLENT FUND

At a recent meeting of the committee of this fund 13 new applicants were assisted and 41 grants were renewed to beneficiaries. In all £1398 was voted. The following particulars of a few cases helped indicate the kind of work undertaken.

M. B., 1933, aged 27, who was responsible for the maintenance of his mother and two younger brothers, had been prevented from taking up a salaried post owing to being in hospital for an operation and was without means. Fund voted £45.

L.R.C.P. Irel., aged 71. In 1935 he had a severe attack of hemiplegia, which affected his speech and legs. Although improved in health he has great difficulty in obtaining employment owing to his deafness, speech, and age. He is earning 10s. a week and is in receipt of the old age pension of 10s. a week. His wife was operated on in 1934 and is in a very weak state of health. She has the charge of a mentally defective daughter, and is endeavouring to increase her income by taking lodgers. Fund voted £40 per annum to the doctor and £26 to his wife.

Widow of medical man aged 67. Suffering from pernicious anemia; has been operated for cataract and has lost one eye. On the death of her husband in 1936 she was left with her daughter in great financial difficulties, the only asset being the possible sale of the practice for £400. Two sisters-in-law, both in very poor circumstances, have given all assistance within their powers. Fund voted £26 per annum and a special gift of £10.

Widow of medical man aged 33, left on the death of her husband with three children aged 5, 2½ years, and 6 months, and a capital sum of under £2000. The Ladies' Guild will help with education.

Daughter of medical man aged 54, suffering from diabetes, has an income of £60 per annum. Fund voted £26 per annum.

This is the centenary year of the fund and a special appeal is being made for new subscribers to raise the annual income by subscriptions and donations to £20,000. From the present income of £14,000 allowances of £40 and £26 are made to medical practitioners and their dependents respectively. The increased income would enable the committee to raise these allowances to £52 and £36. An appeal is also being made this year for special donations to create a fund from which larger grants can be voted to very urgent and distressing cases, and which may be used to help with the training of widows and orphan sons and daughters of medical practitioners to enable them to be self-supporting. Cheques should be made payable to the hon. treasurer of the Fund, 11, Chandos-street, London, W.1.

**LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY LIMITED.**—The annual general meeting of this society will be held at Victory House, Leicester-square, London, on Wednesday, May 6th, at 4 P.M., to receive and adopt the annual report and balance sheet, and to transact other business of the society.

**INTERNATIONAL ASSOCIATION FOR PREVENTION OF BLINDNESS.**—The general assembly of this association and of the International Organisation of the Campaign against Trachoma will be held at 3 P.M. on Monday, May 11th, at the Centre Marcelin Berthelot, 28 bis, rue St.-Dominique, Paris. Prof. de Lapersonne, the president, will take the chair, and communications will be made by Dr. Park Lewis, Prof. F. Terrien, Mr. R. P. Wilson, Mr. A. F. MacCallan, and Mr. Bishop Harman. Further particulars may be had from the secretary at 66, Boulevard Saint-Michel, Paris.

## Medical Diary

### SOCIETIES

- ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.**  
**TUESDAY, April 21st.**—5.30 P.M. Meeting of Fellows.  
*Psychiatry and Disease in Children.* 8.30 P.M. Dr. William Moodie and Dr. Reginald Miller: Enuresis.
- THURSDAY.**  
*Dermatology.* 5 P.M. (Cases at 4 P.M.) Dr. H. W. Barber: 1. Hereditary Alopecia in Mother and Daughter. Dr. G. B. Dowling: 2. Congenital Developmental Abnormality. Dr. A. C. Roxburgh and Dr. R. Klaber: 3. Case for Diagnosis. Dr. Klaber: 4. Idiopathic Hypochromic Anæmia with Dermatitis Herpetiformis. Dr. Klaber and Dr. Freundenthal: 5-6. Blue Nævi (Jadassohn). Dr. G. Bamber: 7. Keratosis of the Nipples. Dr. G. Heggs: 8. Aplasia Phalangium. Dr. R. D. Moyle: 9. Cystic Hygroma with Recurrences in the Skin. Prof. L. J. Witts: 10. Dermatomyositis.  
*Urology.* 8.30 P.M. Mr. O. L. Addison: Urology in Children.
- FRIDAY.**  
*Disease in Children.* Cases will be shown at 4.30 P.M.  
*Epidemiology and State Medicine.* 8.30 P.M. Dr. A. D. Gardner: Prophylaxis, Treatment, and Bacteriology of Pertussis.
- MEDICO-LE GAL SOCIETY.**  
**THURSDAY, April 23rd.**—8.30 P.M. (Mansion House, 26, Portland-place, W.), Prof. Laurie: The Application of Microscopic Methods to Deciding the History and Origin of Pictures.
- CHELSEA CLINICAL SOCIETY.**  
**TUESDAY, April 21st.**—8.30 P.M. (Hotel Rembrandt, Thurloe-place, S.W.), Prof. J. A. Gunn and Dr. A. J. D. Cameron: The Trend of Modern Therapy.
- PADDINGTON MEDICAL SOCIETY.**  
**TUESDAY, April 21st.**—9 P.M. (Great Western Royal Hotel, Paddington, W.), Dr. Maurice Shaw: The Backward Bowel.
- SOCIETY FOR THE STUDY OF INEBRIETY.**  
**TUESDAY, April 21st.**—4 P.M. (11, Chandos-street, W.), Annual General Meeting. Dr. J. D. Rolleston: On Snuff-taking.
- ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY,**  
 5, Lisle-street, W.C.  
**WEDNESDAY, April 22nd.**—4.15 P.M., Clinical Cases. 5 P.M., Dr. George Bray: The Cutaneous Manifestations of Allergy.
- LECTURES, ADDRESSES, DEMONSTRATIONS, &c.**
- UNIVERSITY OF BIRMINGHAM.**  
**TUESDAY, April 21st.**—3.30 P.M. (General Hospital), Mr. A. B. Danby: Recent Advances in the Diagnosis and Treatment of the Toxæmia of Pregnancy.  
**FRIDAY (Queen's Hospital), 3.30 P.M.,** Dr. J. F. Brailsford: The Possibilities of Antenatal Radiography in General Practice.
- BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane-road, W.**  
**MONDAY, April 20th.**—2.15 P.M., Dr. Duncan White: Radiological Demonstration.  
**TUESDAY.**—2 P.M., Prof. E. H. Kettle: Pathological Lecture-demonstration. 3 P.M., Mr. E. J. King, Ph.D.: Phosphatase in Bone Formation and in Bone Disease.  
**WEDNESDAY.**—Noon, clinical and pathological conference (medical). 2.30 P.M., clinical and pathological conference (surgical).  
**THURSDAY.**—2.30 P.M., Dr. W. S. C. Copeman: Arthritis. 3 P.M., Dr. Chassar Moir: Operative Obstetrics.  
**FRIDAY.**—2.15 P.M., Dr. A. A. Davis: Gynecological Pathology. 3.30 P.M., Dr. Alan Moncrieff: Hygiene of the New-born Child. 5 P.M., Sir James Walton: The Surgical Aspects of Dyspepsia.  
 Daily, 10 A.M. to 4 P.M., medical clinics, surgical clinics or operations, obstetric and gynecological clinics or operations, refresher course for general practitioners.
- FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.**  
**MONDAY, April 20th, to SATURDAY, April 25th.**—**ROYAL EYE HOSPITAL, St. George's-circus, S.E.** Afternoon course in ophthalmology.—**ST. MARK'S HOSPITAL, City-road, E.C.** All-day course in proctology. Courses are open only to members of the fellowship.
- HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.**  
**WEDNESDAY, April 22nd.**—2 P.M., Mr. Denis Browne: Cleft Palate and Hare-lip. 3 P.M., Mr. H. C. Apperly: Irregularities of the Teeth and Jaws.  
 Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.
- NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W.**  
**TUESDAY, April 21st.**—5.30 P.M., Dr. F. W. Price: Chronic Myocardial Disease.
- MANCHESTER ROYAL INFIRMARY.**  
**TUESDAY, April 21st.**—4.15 P.M., Dr. F. E. Tylecote: The Physician and the Menopause.  
**FRIDAY.**—4.15 P.M., Mr. John Morley: Demonstration of Surgical Cases.
- GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.**  
**WEDNESDAY, April 22nd.**—4.15 P.M. (Western Infirmary), Mr. J. Mill Renton: Toxic Goitre and its Treatment.

## Appointments

**ARMIT, ADAM, M.B. Edin., D.P.H.**, has been appointed Medical Officer for Chadderton.

**BROWN, C. METCALFE, M.D. Glasg., D.P.H.**, Medical Officer of Health for Middlesbrough.

**EDWARDS, L. M., M.D. Wales**, Assistant Resident Medical Officer at the City of London Maternity Hospital.

**GARLAND, H. G., M.D. Leeds, M.R.C.P. Lond.**, Consultant Assistant Physician to St. James's Hospital, Leeds.

**HARTFALL, S. J., M.D. Leeds, M.R.C.P. Lond.**, Consultant Assistant Physician to St. James's Hospital, Leeds.

**HUDSON, E. H., M.B. Camb., M.R.C.P. Lond.**, Hon. Assistant Physician to the West London Hospital.

**KIMBELL, C. W., M.B. N.Z.**, Resident Medical Officer at the City of London Maternity Hospital.

**MURRAY, D. S., M.B. Glasg.**, Assistant Pathologist to the West London Hospital.

**ROBERTSON, MARGARET F., M.B. Leeds**, Medical Officer to Maternity and Child Welfare for Middlesbrough.

**WADE, C. H. T., M.B. Manch., D.P.H.**, Deputy Medical Superintendent, Baguley Sanatorium, near Altrincham.

**Certifying Surgeons under the Factory and Workshop Acts:**  
**Dr. D. J. EVANS** (Cowbridge District, Glamorgan); **Dr. J. PRINGLE** (Manchester South East District, Lancs.); **Dr. W. R. MAXWELL** (Rhondda (Porth) District, Glamorgan); **Dr. G. R. GARDNER** (Larkhall District, Lanarkshire).

## Vacancies

*For further information refer to the advertisement columns*

**Accrington, Victoria Hospital.**—H.S. £150.

**Altrincham General Hospital.**—Jun. H.S. At rate of £120.

**Ashton-under-Lyme District Infirmary.**—H.S. At rate of £150.

**Ayr County Council.**—Asst. M.O. £500.

**Birmingham, St. Chad's Hospital.**—Jun. Res. M.O. At rate of £150.

**Birmingham, Selly Oak Hospital.**—Jun. M.O. At rate of £200.

**Bradford Royal Infirmary.**—Two H.S.'s. Each at rate of £135.

**Bristol Eye Hospital.**—Jun. Res. H.S. £100.

**British Postgraduate Medical School, Ducane-road, W.**—H.P.

**Burnley Victoria Hospital.**—H.P. At rate of £150.

**Burton-on-Trent, Brelby Hall Orthopaedic Hospital.**—Res. H.S. At rate of £150.

**Cambridge, Addenbrooke's Hospital.**—Res. Anaesthetist, &c. At rate of £130.

**Canterbury, Kent and Canterbury Hospital.**—H.S. At rate of £125.

**Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.**—Hon. Assts. in Out-patient Dept.

**Chester City Hospital.**—Sen. Res. M.O. £400.

**Cowentry and Warwickshire Hospital.**—Res. H.S. £125.

**Doncaster, Royal Infirmary and Dispensary.**—Res. Anaesthetist. Also H.S. Each at rate of £175.

**Ealing, King Edward Memorial Hospital.**—Sen. Res. M.O. At rate of £250.

**Eastbourne, Princess Alice Memorial Hospital.**—Psychologist.

**Evelina Hospital for Sick Children, Southwark, S.E.**—H.S. £120.

**General Lying-in Hospital, York-road, Lambeth, S.E.**—Jun. Res. M.O. and Anaesthetist. At rate of £100.

**Hampstead General and N.W. London Hospital.**—Physician to Out-patients.

**Harrogate and District General Hospital.**—H.S. At rate of £150.

**Home Office, Whitehall, S.W.**—Medical Inspector for Children's Branch. £738.

**Hospital for Sick Children, Great Ormond-street, W.C.**—Res. M.O. for Country Branch. At rate of £250. Also Surg. Reg. £200.

**Hove General Hospital.**—Res. M.O. At rate of £150.

**Huddersfield Royal Infirmary.**—Cas. O. £200. Also H.P. and Res. Anaesthetist. Also two H.S.'s. Each at rate of £150.

**Hull, Beverley-road Institution.**—Asst. M.O. £350.

**Hull Royal Infirmary.**—H.P. to Sutton Branch Hospital. At rate of £160. Also Second Cas. O. At rate of £150.

**Ipswich, East Suffolk and Ipswich Hospital.**—Cas. O. £168. Also H.S. £144.

**Kidderminster and District General Hospital.**—H.S. £150.

**Lancashire Mental Deficiency Acts Committee.**—Asst. M.O. £550.

**Leicester, City General Hospital.**—Res. M.O. At rate of £300.

**Liverpool, Fazakerley Sanatorium.**—Res. Asst. M.O. £200.

**Liverpool, Ministry of Pensions Hospital, Mossley Hill.**—Asst. M.O. At rate of £300.

**Liverpool Sanatorium, Delamere Forest, Frodsham.**—Second Asst. to Med. Supt. £200.

**London Jewish Hospital, Stepney Green, E.**—Res. M.O. and H.P. At rate of £150. Also H.S. and Cas. O. Each at rate of £100.

**Macclesfield General Infirmary.**—Second H.S. At rate of £150.

**Manchester, Christie Hospital and Holt Radium Institute.**—Asst. M.O. £400.

**Manchester City P.H. Dept.**—Asst. M.O.H. £700.

**Manchester Royal Children's Hospital, Pendlebury.**—Res. Surg. O. At rate of £125.

**Manchester Royal Infirmary.**—H.S. to Special Depts. At rate of £50.

**Margate, Royal Sea-Bathing Hospital.**—Asst. Med. Supt. £500.

**Nottingham City Mental Hospital.**—Jun. Asst. M.O. £350.

**Also Locum Tenens M.O. £7 7s. per week.**

**Nottingham General Dispensary.**—Res. Surgeon. £250.

**Oldham Royal Hospital.**—H.S. for Special Depts. and H.P. At rate of £175.

**Penshurst, Cassel Hospital for Functional Nervous Disorders, Swaylands.**—Locum tenens. 10 guineas per week.

**Plymouth City General Hospital.**—Jun. Asst. M.O. £250.

**Princess Beatrice Hospital, Earl's Court, S.W.**—Res. M.O. At rate of £150.

**Queen Mary's Hospital for the East End, Stratford, E.**—Asst. Radiologist. £150.

**Radcliffe-on-Trent, Notts. County Mental Hospital.**—Second Asst. M.O. £459.

**Rotherham Hospital.**—H.P. £180.

**Royal Chest Hospital, City-road, E.C.**—Res. M.O. At rate of £150. Also H.P. At rate of £100.

**Royal London Ophthalmic Hospital, City-road, E.C.**—Two Out-patient Officers. Each £100.

**Royal Naval Medical Service.**—M.O.'s.

**Royal Society, Burlington House, W.**—E. Alan Johnston and Lawrence Research Fellowship in Medicine. £700.

**Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.**—Res. Cas. O. £150. Also H.P. At rate of £100.

**Sheffield Children's Hospital.**—H.S. At rate of £100.

**Surrey County Council.**—Jun. Asst. M.O. for County Sanatorium. At rate of £350.

**Surrey Standing Joint Committee.**—Part-time Pathologist and Medico-Legal Advisor to Surrey Constabulary. 100 guineas with extras.

**Swansea County Borough.**—Asst. M.O. £500.

**Swansea General and Eye Hospital.**—H.P. At rate of £150. Also Cas. O. At rate of £150-£175.

**Taunton and Somerset Hospital.**—H.S. At rate of £100.

**Wolverhampton Royal Hospital.**—H.P. At rate of £125.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Bruton (Somerset), Carlton (Notts), and Keswick (Cumberland). Latest date for receipt of applications April 21st.

## Births, Marriages, and Deaths

### BIRTHS

**CALLENDER.**—On April 6th, at Whitstable, Kent, the wife of Dr. T. A. R. Callender, of a daughter.

**CAPPS.**—On April 6th, the wife of F. C. W. Capps, F.R.C.S. Eng., Park-square East, N.W., of a daughter.

**CUMMING.**—On April 4th, the wife of Dr. John Cumming, of Hove, of a son.

**EAGGER.**—On April 2nd, the wife of Dr. A. A. Eagger, of Exeter, of a son.

**FOWLER.**—On April 7th, at Devonshire-place, the wife of Dr. Eric Fowler, of Crowborough, of a daughter.

**HUDSON.**—On April 11th, at Welbeck-street, the wife of Rupert Vaughan Hudson, F.R.C.S. Eng., of a daughter.

**LEWIS.**—On April 7th, the wife of Dr. Windsor Lewis, Cambridge, of a son.

**NORRIS.**—On April 2nd, at City-road, Finsbury-square, E.C., to Hélène Norris, M.D. Geneva, the wife of Donald C. Norris, M.D. Lond., F.R.C.S. Eng.—a son.

**SINCLAIR.**—On April 6th, at Lewes, the wife of C. Gordon Sinclair, F.R.C.S. Eng., of a son.

**WOODD WALKER.**—On April 13th, at Pembroke-crescent, the wife of Geoffrey Woodd Walker, F.R.C.S. Eng., of Queen Anne-street, W., of a son.

### MARRIAGES

**ASHTON-WOLFE.**—At St. Clement Danes, London, on Feb. 29th, 1936, Eric G. Ashton, M.B., Ch.B. Dub., to Sylvia K. F. Wolfe, M.B., B.S. Lond.

**LIST-CARR.**—On April 4th, at Stone, Staffs. Dr. Howard Meredith List, to Elizabeth Maud, elder daughter of Mr. R. H. Carr, of Stone.

### DEATHS

**BINGLEY.**—On April 10th, at Little Causey, Cranleigh, Ernest Horsford Bingley, M.R.C.S. Eng.

**MITCHELL.**—On April 12th, at Portsmouth, Arthur Martin Mitchell, M.D. Camb.

**PAYNE.**—On April 7th, at Leicester, Alfred Ernest Payne, M.B. Lond.

**PRATT.**—On April 11th, suddenly, at Morchard Bishop, Charles Claridge Pratt, L.M.S.S.A. Lond.

**PRESTON.**—On April 12th, at Mannings Heath, the residence of his sister-in-law, Joseph Charles Preston, L.D.S., of Brighton.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

**HOSPITAL ACCOMMODATION FOR SOUTH MIDDLESEX AND RICHMOND.**—The Minister of Health has sanctioned the raising of a loan of £96,650 by the South Middlesex and Richmond Joint Hospital Board for further accommodation in connexion with the treatment of infectious disease other than small-pox. The money is to be spent on erecting two new pavilion blocks, each containing 24 beds, and three cubicle blocks, each containing 12 beds, a new administration block, a nurses' home, and an operating theatre, together with a house for the medical superintendent and a lodge for the porter.

## ADDRESSES AND ORIGINAL ARTICLES

## ASSESSMENT OF DENTAL SEPSIS AS A FACTOR AFFECTING MEDICAL AND SURGICAL PROCEDURES\*

BY ARTHUR BULLEID, M.R.C.S. Eng., L.D.S.  
ASSISTANT DENTAL SURGEON TO GUY'S HOSPITAL

In defining dental sepsis most dental surgeons agree that the terms "open" and "closed" largely meet the needs of the case. There is no clear-cut difference between the possible effects of the two groups, yet the terms do suggest two clinical pictures. If we accept "open" sepsis as applying to such diseases as caries, gingivitis, and pyorrhœa, we at once visualise conditions in which drainage into the mouth is possible. If we confine the term "closed" sepsis to those dental lesions in which there is no possibility of drainage into the mouth then we shall be able to confine it to pulpless teeth with or without radiographic evidence of apical osteitis; to the so-called "live" teeth with heavy artificial restorations; and to residual infection left in the alveolus after the removal of teeth in late pyorrhœa. I think that it is now becoming more and more generally recognised that dental sepsis, whether of the open or closed type, is but a superadded streptococcal infection and not a sole cause of general disease. This does not lessen its importance but it makes its assessment more difficult. Eradication of the sepsis does not necessarily mean the extraction of teeth, and this is why I think the terms "open" and "closed" are useful from a clinical point of view. No one will deny that caries, gingivitis, and early pyorrhœa can be treated adequately by conservative means, and I shall attempt to show that by adequate clinical and bacteriological methods it is possible, in a large proportion of cases, to assess the importance of the sepsis present.

### BACTERIOLOGY

Open and closed sepsis are similar in that streptococci are the organisms universally found in both types. It must be admitted that the obvious fallacies in the bacteriological findings in open sepsis are almost insurmountable, but in spite of this it seems highly probable that the general manifestations associated with dental sepsis are streptococcal. It can be stated definitely that no other group of organisms that can be cultivated from dental lesions, with the exception of staphylococci, give rise to specific antibodies in the blood-serum of the patients concerned.

It seems to me that much can be learned from an investigation of the bacteriological flora and of the cytology of the exudate from pyorrhœa pockets. In cases of pyorrhœa in which the disease is progressing and in which there is the possibility of toxic absorption, the type of leucocyte is highly important. Polymorphonuclear leucocytes denote active pus-formation. After adequate conservative treatment active pus-formation should have ceased and what leucocytes are present in the smears are chiefly mononuclears. After pockets have been eradicated, either by conservative or surgical means, and the gums have been kept healthy by simple hygiene, direct smears from the gingival trough show hardly any leucocytes, the few present being almost all mononuclears.

The symbiosis of fusiform bacilli and spiral forms, which has been described by many observers, must receive special note. All that can be said at present is that the appearance of the fusospirochaetal flora merely denotes a gum inflammation; there is no evidence that the oral spirochaetes by themselves can produce disease in man, and they confer no humoral immunity. Two other organisms also deserve mention—*Amœba buccalis* and *Leptothrix buccalis*. The former is a protozoan which is actively phagocytic but bears no causal relationship to pyorrhœa. Its presence denotes stagnation and therefore serves an important function in showing that the treatment of the condition is inadequate. The leptothrix is the causal organism in seruminous tartar formation, and its presence shows a particular patient's liability to that condition, a factor of some import in pyorrhœa. In a study of the organism begun in 1921, I was able to grow it on artificial culture medium and produce tartar experimentally in cats' mouths that had previously been tartar-free. I was also able to demonstrate that the organism attracted calcium. Smears made from the exudate expressed from just below the gum margins in patients in whom there is much tartar reveal a large amount of leptothrix mycelium, while in those patients in whom the liability to tartar formation is slight the organism is found in relatively small numbers.

The effect produced on the cytology and flora in cases of open sepsis by both conservative and surgical treatment is very similar. With adequate and effective conservative treatment the ratio of polymorphonuclear to mononuclear leucocytes swings to the side of the latter; the fusospirochaetal flora will mostly be absent and that no amœbæ and only very little leptothrix mycelium will be detected. If this result is not brought about by simple conservative methods then surgical removal of the pockets by gingivectomy is called for, the value of the procedure being checked by the examination of smears from the gingival trough, coupled with the clinical appearance. In those cases in which the desired effect cannot be obtained by these two methods the only logical procedure is to extract the teeth in order to do away with stagnation and to prevent toxic absorption.

We can discuss the bacteriology of closed dental sepsis with a greater degree of certainty, because one of the manifestations of this pathological condition is the presence in the peri-apical space of an encapsulated mass of granulation tissue, firmly adherent to the peri-odontal membrane and remaining attached to the tooth on extraction. By appropriate means it is possible to sterilise the exterior of this granuloma and make cultures from its interior. In 1928 I commenced an investigation on the bacteriology of pulpless teeth and since that time I have examined the bacteriology of more than a thousand teeth.

In all the 400 pulpless teeth with apical granulomata that had been extracted the interiors of the granulomata yielded a growth of streptococci, usually of the *viridans* or indifferent groups, sometimes in pure culture, at other times associated with other organisms.

I have also investigated 600 extracted pulpless teeth, some showing apical osteitis in skiagrams but others with no such evidence. After most careful preliminary sterilisation of the supporting structures, apical cultures were made, using both aerobic and anaerobic methods. None of the teeth in this series had attached granulomata. In all a

\* A Hunterian lecture delivered before the Royal College of Surgeons of England on Jan. 22nd, 1936.

streptococcus was isolated, usually of the *viridans* or indifferent types. In a large percentage of the single-rooted upper teeth in this series the streptococcus was in pure culture, but in the multiple-rooted teeth it was accompanied by other organisms; the only organism consistently found, however, was a streptococcus.

In 20 cases in this series the method of open operation—i.e., cutting down on the apex of the tooth "in situ" by removing the overlying structures—was adopted and in all cases the apical cultures revealed a streptococcus. This suggests, though it does not prove absolutely, that the streptococci isolated from the apices of the extracted pulpless teeth were in fact responsible for the pathological condition. The absence of an area of apical osteitis in the skiagram does not indicate the absence of infection nor does the size of the area denote the potentialities of the infection. On the contrary, pulpless teeth showing no areas of apical osteitis in skiagrams may be passed as harmless, when in fact they are definitely infected.

I have examined bacteriologically 20 teeth with associated acute alveolar abscesses—16 were approached through an external incision and the remaining 4 by evacuating the pus in an exploratory syringe. In all a streptococcus was recovered; it was noted that the percentage of true  $\beta$ -haemolytic streptococci was higher in this series than in the chronic apical infections.

The epithelial linings of 20 cystic new growths have also been examined bacteriologically, 16 being dental cysts and 4 dentigerous; all were approached by the open method, using strict surgical asepsis. All yielded growths of streptococci in aerobic or anaerobic culture, or both. The fluid of the cysts, if clear, was sterile, but if opalescent or purulent, gave a growth of streptococci.

Another type of dental sepsis that is, I think, often missed is connected with the absorption and rounding off of the apices of "live" teeth. This destruction is shown in the skiagram, and bacteriological examination of the apices of these teeth either by open operation or by extraction reveals once again the presence of the ubiquitous streptococcus. I have been able to investigate only 6 of these cases, but in 4 the streptococcus was of the true haemolytic type. The following illustrates the importance of this type of infection.

A patient developed phlebitis in his right leg, which in time cleared up. The only history he gave was that he had previously grazed his heel on a nail in his boot, and this soon healed. Later the phlebitis recurred and yet no obvious focus of infection was found. His teeth were radiographed and it was discovered that one of the lower premolars seemed a good deal shorter than its fellows. There was no pain and tests for vitality were positive. As the phlebitis cleared up there was no dental treatment. Later a recurrence of the trouble led to further skiagrams and another lower premolar tooth had become shortened. Both these teeth were extracted and apical cultures gave a growth of a haemolytic streptococcus. Further absorption of "live" teeth took place and the end-result was the extraction of all his remaining teeth, and subsequent vaccination with the haemolytic streptococcus. Not until this was done did the phlebitis finally disappear.

The case is interesting I think in that it suggests that the infecting streptococcus, which must have gained entrance via the grazed heel, had been carried to the teeth where it manifested itself by eroding the apices. As the primary focus had long since healed the dental focus became all important.

Another type of closed dental infection which I have investigated is that known as residual

osteitis. This is shown in skiagrams as a feathery appearance of the alveolus and may occur in late pyorrhœa when extraction of teeth has been too long delayed. If this feathery alveolus is removed and cultivated the cultures invariably reveal the presence of a streptococcus, usually of the *viridans* or indifferent groups. The following case typifies the importance of this class of infection.

A patient had an early infective arthritis of both knees, which disappeared with the enucleation of tonsils and a few badly infected teeth. Three years later the arthritis of the knees recurred; no focus of infection was discovered until the edentulous lower jaw was radiographed. An area of residual osteitis was revealed extending from the premolar region on one side to the premolar region on the other. This was removed and cultivated, and a streptococcus of the *viridans* group recovered. Subsequent vaccination with this streptococcal antigen brought about a gradual cure.

The last type of closed dental sepsis that I have investigated in collaboration with Ellingham is that found in connexion with "live" teeth in which heavy artificial restorations have been inserted. In a series of 30 cases, 22 were found to contain living bacteria. In 90 per cent. of the latter the organism cultivated from the pulps was a streptococcus occasionally associated with a staphylococcus. In this research all we have been able to demonstrate so far is the presence of the micro-organisms in the "live" pulps and I cannot state dogmatically what their significance is. It seems essential to study the histological appearances of these "live" pulps in conjunction with the bacteriological findings before the results can be correctly interpreted.

It is wise, I think, to group the streptococci found in these areas of closed sepsis because it is well known how deleterious are the effects of the true haemolytic group, whereas the effects of the *viridans* or indifferent groups are much more problematical. In a series I investigated, only 10 per cent. of the cases had streptococci of the true haemolytic group; the other 90 per cent. were divided between the *viridans* and indifferent groups, chiefly the former. In dental lesions the true haemolytic streptococci are found in a higher proportion in acute conditions such as acute alveolar abscess and acute Vincent's infection, in which systemic involvement is always present, though possibly it may not be dangerous.

I attach importance to the possible symbiotic relationship of the yellow staphylococcus and the *viridans* streptococcus. Staphylococci, particularly the *aureus*, are infrequent in dental lesions and their presence is very important, particularly if the patient is also subject to staphylococcal infections such as boils or carbuncles. The following is an example:—

A schoolboy had "toothache" in a lower premolar which had been rather heavily restored and the tooth was extracted under nitrous oxide anaesthesia. Nothing untoward happened for three days and then swelling appeared which spread along the jaw from the symphysis to the articulation on the same side. An incision was made over this swelling by the doctor but no pus was evacuated. The remaining teeth on the same side of the lower jaw were loosened, the periosteum being stripped up. The mouth was intensely dry and hot, and the boy had a high, swinging pyrexia. My colleague, Kelsey Fry, saw the patient with me and inserted a drainage-tube from the site of the original incision right down to the jaw, but found no pus. I cultured the blood and obtained a pure growth of *Staphylococcus aureus*; from the apices of the teeth, which had become so loosened that I was able to pick them out with dressing forceps, I obtained a heavy growth of the yellow staphylococcus, as well as the usual *Streptococcus viridans*. The boy died.

On several occasions I have noted the general disturbance occasioned by the removal of teeth, that on culture have grown streptococci plus yellow staphylococci. It suggests a focus which might give rise to a staphylococcal bacteræmia and so supply the organisms which could cause an osteomyelitis of the long bones, particularly in children. The following case is of interest in this connexion :—

A boy of 14 received a blow on his right shin during a game of hockey. The leg was painful for a few days and showed some bruising, but there was no fracture. The bruising and swelling soon disappeared and no further notice was taken of the injury. Some six weeks later the boy developed an acute alveolar abscess in connexion with an upper premolar tooth, which was extracted. Cultures from the evacuated pus gave a heavy growth of *Staphylococcus aureus* associated with *Streptococcus viridans*. Recovery from the extraction was uneventful, but about a week later the right leg became painful at the site of the original blow. A surgeon was called in and diagnosed osteomyelitis, which was confirmed by operation. It was suggested that the staphylococcus gained access to the blood at the time of the extraction of the tooth and that the previous injury to the leg localised the organism.

#### CHANGES IN THE BLOOD

Recently Elliott, instigated by Okell, has carried out an investigation in which I have had a practical interest. Elliott has proved that the multiple extraction of teeth in mouths showing severe dental sepsis of both open and closed types resulted in a large percentage of cases in a temporary *Streptococcus viridans* bacteræmia. Positive blood cultures of this group of streptococci were recorded in 75 per cent. of the cases investigated, the bacteræmia lasting about a quarter of an hour following the extraction of the teeth. In 10 per cent. of the cases, patients with severe dental sepsis were found to have a positive *S. viridans* bacteræmia irrespective of any operative interference. It seems logical to suggest that this "leak," which in normal patients in good health is of little import, might determine the infection of more remote structures if they were in a condition of lowered resistance.

Whether the streptococcus isolated from the blood is identical with that found at the apices of the extracted teeth or from the pyorrhœa pockets is difficult to prove, but at least they are both of the *viridans* group. I am at present engaged in an investigation to show whether this leak of streptococci into the blood is greater numerically and in a larger proportion of patients with clean mouths but who have pulpless teeth, than it is in those in whom the sepsis is chiefly of the open type. It may be merely the extent and degree of the trauma rather than the type of sepsis which is responsible for the bacteræmia, though it must not be forgotten that there was a bacteræmia in 10 per cent. of those in whom there was no operative interference.

The blood picture of patients with open dental sepsis is not abnormal enough to be very informative. In 70 patients suffering with pyorrhœa, in whom no systemic disease was observed, the blood counts showed very little difference from normal. Occasionally a slight decrease was noted in the hæmoglobin percentage, or in the number of red and white corpuscles, but otherwise there was no difference from normal. In 4 patients in whom the pyorrhœic state was very advanced there was a slight leucocytosis. In 10 cases of acute alveolar abscess there was a definite leucocytosis of 12,000–15,000 per c.mm., and differential counts showed an absolute increase in the polymorphonuclear neutrophils and a corre-

sponding decrease in the lymphocytes; the hæmoglobin percentage and the red cell count were only slightly decreased from normal. In 5 cases of acute Vincent's infection of the gums there was a slight but definite leucocytosis. In 30 patients with four or more pulpless teeth of long standing, the blood picture was slightly abnormal, irrespective of whether the radiograms of the teeth revealed apical osteitis or not. The chief points noted were a leucopenia, a decreased hæmoglobin percentage, and a lessened number of red cells; in the differential leucocyte counts there was a slight swing to the lymphocytic side. It seems, however, true to say that dental sepsis by itself, whether open or closed, does not produce changes in the blood picture that are of great significance when one realises the normal daily variations. All I can say from my own observations is that the changes in the blood which I have noted have been rather more marked in closed than in open sepsis.

#### RELATION TO SYSTEMIC DISEASE

Now for a consideration of those patients in whom the dental sepsis and some systemic condition are found together. It must not be thought that because both may be found in the same patient that the dental sepsis is necessarily the cause of the general disease.

Knott and others have confirmed the germicidal effect of the hydrochloric acid of the gastric juice and have shown that the germicidal effect of organic acids is almost negligible in the absence of free hydrochloric acid. When chronic gastritis is present, owing to prolonged mechanical irritation of the gastric mucous membrane by bolting food, and by alcohol, tobacco, &c., the normal secretion of hydrochloric acid suffers. If the exciting cause of the gastritis continues even when complete achlorhydria has developed, the gastritis becomes progressively worse; it is in these cases that the streptococcal flora that is swallowed becomes important. There seems no reason to doubt that the swallowed pus itself may act as an irritant.

We are rather prone to think of open dental sepsis purely in relation to the bacterial flora found and to forget the chemical side of the picture. We swallow more than bacteria, and it seems feasible to suggest that the swallowing of pus and of the decomposition products of protein and carbohydrate metabolism may irritate the gastric mucous membrane. Removal of the decomposing food material and the pus found in pyorrhœa pockets is of undoubted importance.

In some preliminary work on the chemistry of the products of decomposition of food material found in mouths with open dental sepsis, some interesting results have been obtained, and it seems as if further investigation is indicated. If the material found around the teeth and gums in pyorrhœic mouths is washed out with sterile water and analysed it has been possible to detect the decomposition products of both carbohydrates and proteins. The decomposition products of the former are the higher alcohols, and of the latter putrefactive alkaloids, which possess basic properties and are nitrogen derivatives; some are toxic, some harmless. At present I cannot say definitely if the higher alcohols are present in these pyorrhœic mouths, though the furfural test was always positive, because mucin possesses a carbohydrate group and will give this reaction. Members of the amine group have been isolated as dry salts and primary, secondary, and tertiary

amines have all been demonstrated. The toxic nature of these amines has been tested on the heart of the pithed frog. The primary and tertiary amines were non-toxic but the secondary were definitely toxic, and the heart did not recover after introducing atropine sulphate, which suggests that these amines are not of the muscarine group.

Another interesting experiment was to grow the organisms found in the washings from the pyorrhœic mouths on culture medium well enriched with sugars. The amines derived from the inoculated culture medium were all non-toxic to the frog's heart, and so were the amines derived from the uninoculated culture medium.

In any assessment of the importance of open sepsis the feasibility must be considered of preventing these decomposing food products from being swallowed by removing them from around the teeth. If this can be done by conservative methods, well and good, but if not, extraction of teeth is a logical procedure.

Now it is recognised by all that if a gastric or duodenal ulcer of long standing fails to react to medical treatment the aid of the surgeon is essential, and it is in these cases that I would assess the importance of dental sepsis, whether open or closed, much higher than previously. When the surgeon operates it is important that the interference shall be successful, and that any condition which might prejudice the success of the operation must be eradicated. It is notorious that streptococci, even those of low virulence, attack wounds, and as we know that the streptococci from pulpless teeth can reach the site of operation via the blood stream, pulpless teeth should not be tolerated. Even the streptococci from open dental sepsis, which when swallowed normally fail to pass the acid barrier, may yet survive in the stomach in the first 48 hours after operation and lodge at the operation site. This would be a definite risk when the acid barrier is replaced by one of hypo- or achlorhydria following the gastrojejunostomy or partial gastrectomy. Thus if there is any dental sepsis in a patient before a contemplated operation its treatment must be more radical than when surgical measures are thought unnecessary. In these cases I would advise against the retention of any teeth that are the site of a streptococcal infection and would strongly suggest that the necessary dental treatment is carried out as early as is conveniently possible before the major operation. It must be realised that the general surgeon has every reason to object to the presence of pus and "dirt," even if it is sterile.

Statistics prove that the breaking down of operation wounds or the recurrence of malignant disease is greater in mouths in which sepsis is present than it is in those in whom it has been eradicated. One fact which most observers have noticed is that, if any teeth are spared in a mouth in which a major surgical operation has been performed, they subsequently show clear evidence of infection, even if at the time of operation they appeared healthy. This suggests that it is wise to render a mouth edentulous before an extensive operation. In fact, if a major operation is contemplated in any region of the body I think it is wise to remove at least all pulpless teeth, because of the potential risk of streptococci passing via the blood stream to the site of operation, a risk which I think is definitely greater in closed than in open sepsis. If one always followed sound surgical opinion all possible foci of infection should be removed, and with this we must neces-

sarily agree, even though the infection is only an "overload." If the removal of teeth did not result in any mutilation of the patient there would be no sound reason for keeping teeth once they had become the seat of disease. As, however, they do serve a most useful as well as aesthetic purpose, then we must modify our treatment accordingly. This is, I think, a justification for the dental surgeon who at first attempts to remove open dental sepsis by conservative methods and who admits the necessity for the extraction of teeth only when this fails. As the sepsis in pulpless teeth cannot be eradicated by any known conservative method there seems to be no sound justification for retaining them. The only exception I would make is in the single-rooted upper tooth on which apicectomy can be performed with some hope of success.

Now is there any possibility of correlating the dental and systemic conditions, when such are present, by any known and accepted bacteriological methods? Personally I am inclined to think that in the present state of our knowledge there is as yet no certain means of doing so. The work of Okell and Elliott, to which I have already referred, offers a very useful method which should be more fully explored. In a series of 500 cases I carried out complement-fixation tests on the patient's serum and the dental streptococcal antigen, but they were all universally negative. Agglutination seems to be a little more hopeful, but it is impossible to state dogmatically what reliance can be placed on the results. Over a period of some six years I have made a practice of testing the dental streptococcus isolated from the apices of extracted teeth against the patient's serum. In some I have obtained positive agglutination in a sufficiently high dilution of the patient's serum to suggest a specific connexion between the dental and systemic conditions. The results, of course, depend on obtaining the correct strain of streptococcus from the dental lesions and this is by no means always certain. Recently I have been using the streptococcal strain isolated from the blood after the extraction of teeth and, with this as antigen, the agglutination results have been more encouraging, but that is all I can truthfully say.

#### ASEPSIS IN ORAL SURGERY

Opening up cavities in bone is always fraught with some risk; this is minimised if surgical asepsis is observed as far as is possible. There is always the risk of the spread of streptococci, and sometimes the yellow staphylococci, by the blood stream when surgical procedures in the mouth are being carried out, particularly if they are accompanied by trauma and laceration of tissues, which unfortunately is rather common in the oral cavity. This should make the dental surgeon pause before he carries out multiple extractions of teeth or causes unnecessary trauma by extensive surgical procedures when simpler methods would suffice. It is unusual to find dangerous reactions following dental operations in the mouth only because the dental streptococci are of low virulence, but this does not exonerate us if untoward results do follow. If the tissues of any organ are in a state of receptiveness for bacterial invasion, then extensive dental operations are apt to cause local infection that less extensive operations might prevent.

#### CONCLUSIONS

It must be allowed, I think, that dental sepsis per se is very rarely the sole cause of any systemic

condition. It is, rather, a streptococcal overload that should be eradicated if possible. This does not mean that all open dental sepsis such as pyorrhœa necessitates the removal of any or all the teeth, but it does mean that this sepsis should be treated and eradicated. If conservative methods are sufficient to preserve the balance between infecting agent and the patient's resistance, by all means employ conservative methods. If the balance swings against the resistance, then the overload should be removed and the dental surgeon should not be bigoted in refusing to extract infected teeth if conservative methods fail to prevent the infection spreading to more remote parts.

I am of the opinion that, as no conservative procedures yet known are capable of rendering pulpless teeth sterile, or rather, of preserving sterility for any length of time, they should not be tolerated. The only exceptions are the single-rooted upper teeth on which apicectomy can easily and safely be performed. If surgical procedures are necessary in any part of the body, as it is recognised that streptococcal invasion prejudices the success of such operations, no gross dental sepsis should be allowed, particularly if it is connected with pulpless teeth. This also suggests that everything possible should be done to prevent infection of the dental pulp.

Bacteriological investigations have a very important place in the assessment picture, but I sometimes feel that the magnification conferred by the microscope is nullified by the microscopic mind. Careful blood culture work and serological tests such as agglutination are of undoubted value and importance, and may become more so as our technique improves. Only experience, and particularly clinical experience, can at present guide our faltering steps along the right path of a more rational assessment of the evils of dental sepsis. Clinical experience can be aided by laboratory methods, which must, however, remain complementary. Every case must be treated on its merits. Some can shoulder a load of sepsis with much greater impunity than others, but sooner or later, the streptococcal overload will take its toll and therefore should never be entirely neglected. The habits and environment of patients may decide whether the dental sepsis is only a pin-prick or a knock-out blow.

If we can only employ a sweet reasonableness and yet remember Euclid's axiom that the whole is always greater than the part, I feel sure the storm of controversy that has so long raged around this question of dental sepsis will die down, and out of the tempest there will come a ship.

## INDUCTION OF LABOUR FOR DISPROPORTION

A CRITICAL ANALYSIS OF ONE HUNDRED CONSECUTIVE CASES OF SURGICAL INDUCTION FOR REAL OR SUSPECTED DISPROPORTION

By J. H. PEEL, B.M. Oxon., F.R.C.S. Eng., M.C.O.G.  
FIRST ASSISTANT IN THE OBSTETRIC DEPARTMENT,  
KING'S COLLEGE HOSPITAL, LONDON

THE problem of the correct way to deal with minor degrees of disproportion between the foetal head and the maternal pelvis is one which has given rise to a good deal of discussion in recent years. Three ways of treating these cases are universally accepted—viz., Cæsarean section, trial labour, and induction of premature labour. I think I am justified in saying that few, if any, obstetricians resort to induction of labour before the thirty-sixth week of pregnancy, unless in very exceptional circumstances. If the disproportion is so great that induction would be necessary before the thirty-sixth week, it is better, in the interest of the mother as well as the child, to deliver the baby by Cæsarean section. In other words, the treatment of gross degrees of disproportion, except when due to such foetal abnormalities as hydrocephalus, by deliberate Cæsarean section done just before term is universally accepted.

It is in considering minor degrees of disproportion that one finds two schools of thought—one advocating induction of labour at the appropriate date between the thirty-sixth week and term, the other preferring to allow all such cases to have a trial of labour. So far as the statistical part of what follows in this article is concerned, it is offered as a negative piece of evidence in favour of the method of trial labour, because to my mind it demonstrates the unsatisfactory result of surgical induction of labour.

I am well aware that the theoretical advantages of premature induction of labour are many. I am also well aware that at some future date, when the exact physiological cause of the onset of labour is fully understood, and one is able to apply the exact physiological stimulus, either by injection or by mouth, so as to constitute a medical induction of labour, one will probably have to modify one's views very considerably. But at the present moment medical induction of premature labour is both uncertain and not without danger, whereas surgical induction, though more certain, is fraught with very considerable danger, both to mother and child.

The ultimate object of antenatal care is to reduce to a minimum both maternal and foetal mortality and morbidity. One reason at least why antenatal care seems to be failing in this object is that not infrequently, in trying to prevent one possible disaster, interference is made which leads to a disaster more serious than the imaginary one which an attempt has been made to avoid. Many deliberate Cæsarean sections and instrumental inductions of premature labour can be unquestionably regarded as meddling midwifery. Writing on the subject of Cæsarean section and induction of labour, Prof. F. J. Browne<sup>1</sup> says:

"Much of the interference is probably unnecessary, and constitutes meddling midwifery, for in most cases delivery would have taken place without trouble had the patient been left alone. The intervention would not matter if these operations were always safe, but we know they are not. I have shown, for example, that out of 173 deaths in nine maternity hospitals, all staffed by experts, 8, or 1 in 20, followed directly on induction;

death being due to sepsis, hæmorrhage or anæsthetic complications."

#### ADVANTAGES AND DISADVANTAGES OF INDUCTION

Before considering the actual statistics of the cases I have analysed, it will be useful to discuss the theoretical and practical advantages and disadvantages of premature induction of labour for disproportion. The outstanding advantage is obviously that the dangerous results of disproportion in labour are avoided. This is true in the majority of cases, but because the induction is often left until the latest possible moment, and because errors of judgment are inevitable, even by experts, obstructed labour will occasionally occur after induction. One is then faced with the alternative of craniotomy or Cæsarean section, and the latter operation following on the insertion of bougies, bags, or the like, is a most dangerous risk to the patient and one which has a relatively high mortality. If, on the other hand, one resorts to craniotomy after induction the whole object of the interference is nullified. The second great advantage is that a Cæsarean section, with the attendant risks, may be avoided. But because the induction of labour is so often entirely unnecessary, and the patients induced would have delivered themselves quite easily when they started labour spontaneously, the Cæsarean section rate is not greatly increased if the practice of giving the patient a trial of labour is carried out. At King's College Hospital the practice of inducing labour for disproportion in primigravida has practically been abandoned for the past three years. In 1930, 31 total Cæsarean sections were performed and 76 inductions of labour. In 1934, although the Cæsareans had increased to 46, the inductions had been reduced to 18. Actually in 1934, 40 more patients were delivered in the maternity ward. I realise that these figures cannot be taken too literally, but they illustrate the point I am trying to explain.

What then are the disadvantages and risks of surgical induction of labour in these cases? They are both maternal and fetal. Of the maternal risks first and foremost comes sepsis. Even the most enthusiastic supporter of induction of labour will have to admit the danger of sepsis. The literature shows clearly that this risk of sepsis is not a figment of the imagination. Hewitt, Towart, and Baird,<sup>2</sup> reporting 34 cases of bougie induction, mention 2 deaths from uterine sepsis, and stress the risk of sepsis even though the bougies are unsuccessful in inducing labour and have to be removed. Morton<sup>3</sup> in 1929 reports 132 cases of bougie induction. There were 4 deaths—2 being due to sepsis. The notifiable morbidity-rate was 18.6 per cent. He compares a series of bougie inductions and bag inductions and concludes that the risk of sepsis is even greater in the case of bag induction. Reis<sup>4</sup> in 1929, also reviewing the history of induction of labour and all the known methods, states that even medical induction increased the rate of morbidity by 15–20 per cent., and quoted a 33 per cent. morbidity for induction by means of a bag. On the other hand Bannister,<sup>5</sup> opening a discussion at the British Medical Association in 1926, reports much better results from the point of view of sepsis. He had only 1 maternal death in 745 cases and only a 4 per cent. morbidity. My own figures amply confirm the great risk of sepsis.

The other maternal disadvantages, although of less importance than the disadvantage of sepsis, are none the less real. Cases are recorded of the uterus having been perforated by a bougie. Occasionally, in unskilled hands, a great deal of placental separation may be caused by bougies with resultant

hæmorrhage and fetal death in utero. In addition there is the strong objection which can be raised against all known methods of induction of labour—namely, that quite often the uterine action in labour is inadequate, so that such complications as inertia, contraction rings, spasm of the lower segment, and retention of the placenta are more common after induced labour than after labour which starts spontaneously. Barnes,<sup>6</sup> writing as long ago as 1868 on the question of induction of labour, says: "Labour finds the uterus in an imperfect state of development, with imperfect contractile power, and with greater resistance of the cervix," and again: "The uterus is called upon—suddenly and before its time—to do that for which it is not prepared." These complications at first sight are not themselves so serious, but with them goes the necessity for increased manipulations—the inevitable increased exhaustion of the patient and so the increased risks of maternal mortality and morbidity. In addition they lead to, in fact are chiefly responsible for, the increased fetal mortality. This increased fetal mortality is a further disadvantage of this time-honoured way of dealing with these cases. Bannister,<sup>5</sup> in the same address in 1926 in which he quotes such low figures for maternal mortality and morbidity, has to admit a 12.6 per cent. fetal mortality, and one is rather amazed to read that this is regarded as a satisfactory state of affairs. The chief object of the interference is nullified if a dead baby is born.

#### ANALYSIS OF CASES

I have taken 100 consecutive cases of surgical induction of labour during the period 1927–34 at King's College Hospital. I have entirely excluded induction for any other reason such as toxæmia or antepartum hæmorrhage, because in these cases there are additional factors to affect the maternal and fetal mortality and morbidity. In every case induction was done primarily because it was feared that if pregnancy were allowed to continue there might arise serious disproportion between the baby's head and the maternal pelvis. Only three methods have been employed—bougies, artificial rupture of the membranes, and the stomach-tube (one case). From a perusal of the literature I have come to the conclusion that the result of other methods of surgical induction are little if any better. Of the 100 cases 90 were induced by bougie, 9 by artificial rupture of the membranes. Reliable conclusion obviously cannot be drawn from 9 cases, but the results with artificial rupture of the membranes are better than those with bougies, so that the total figures are improved by their inclusion. I have included them in order to make the sequence consecutive and not in any way selective.

#### Results of Surgical Induction

Method.	Hours before onset of labour.		Total duration of labour.	
	Pgr.	Mgr.	Pgr.	Mgr.
Bougie (90 cases)	35 hrs., 40 mins.	24 hrs., 5 mins.	32 hrs., 49 mins.	18 hrs., 59 mins.
Artificial rupture of membranes (9 cases)	3 hrs., 30 mins.	1 hour.	22 hrs., 30 mins.	6 hrs., 35 mins.
Stomach-tube (1 case)	48 hours.	—	33 hours.	—

Pgr. and Mgr. = Primigravida and multigravida respectively.

Of the 100 cases 60 were primigravida and 40 multigravida. The accompanying Table shows the average time of onset of labour and duration of labour in each group.

The Table shows the prolongation of labour in those cases induced by bougies. Analysing the labour still further in the 90 cases induced by bougies I find that of the primigravidæ 49 per cent., of the multigravidæ 43.2 per cent., were classified as having inertia (average 46.6 per cent.). The forceps rate in the two groups was as follows :—

Primigravidæ ..	..	..	..	..	35.8 per cent.
Multigravidæ ..	..	..	..	..	5.4 " "
Average ..	..	..	..	..	23.3 " "

The average forceps rate at King's College Hospital during the past five years is 8.7 per cent., so that in these cases the necessity for forceps was increased nearly threefold. There was abnormal postpartum hæmorrhage in 9 cases, necessitating manual removal of the placenta in 3.

The total stillbirth-rate worked out to be 14 per cent., the average of all cases in the past five years was 5.05 per cent. In the case of the primigravidæ induced by bougie the stillbirth-rate was 20.8 per cent. This single figure alone should surely make one hesitate ever to induce labour by bougie in cases of suspected disproportion in a primigravida. The two reasons for the high stillbirth-rate in these cases are probably the following :—

1. The baby is often premature and therefore less able to stand the stress and strain of a difficult labour, particularly instrumental delivery, than a mature infant.
2. Labour is often prolonged and has to be terminated by forceps.

Bannister mentions the high incidence of prolapse of the cord (1.6 per cent.) but this did not occur at all in this series of cases.

There was one maternal death in the series. The patient was a primigravida, and the induction was by bougies. She was in labour 70 hours, delivered by forceps of a stillborn baby, and had a postpartum hæmorrhage necessitating manual removal of the placenta. There is little wonder that she developed uterine sepsis, after this series of catastrophes. The maternal morbidity was as follows :—

Group 1.—Total notifiable morbidity ..	..	11	Per cent.
Group 2.—Total morbidity (temperature persisting above 99.6° F. with evidence of mild uterine infection) ..	..	45	

The average duration of pyrexia (Group 2) was 10 days. In all but one case the pyrexia followed bougie induction, and they are further classified as follows :—

Notifiable pyrexia.		Pyrexia above 99.6°.	
	Per cent.		Per cent.
Primigravidæ—	} = 12.2	Primigravidæ—	} = 48.8
10 cases .. 18.8		31 cases .. 58.5	
Multigravidæ—	}	Multigravidæ—	}
1 case .. 2.7		13 cases .. 35.1	

The fact that the morbidity is higher in the primigravidæ than the multigravidæ suggests that the increased maternal exhaustion and increased necessity for interference in the delivery are additional factors.

It may be asked why I have mentioned morbidity other than notifiable morbidity, and argued that pyrexia less than the notifiable one of 100.4° are of little significance. But notifiable pyrexia can often be very misleading. A patient can run a temperature of 100.2° for a month without being regarded as a notifiable case, whereas a patient may have a temperature of 100.6° on two successive evenings and therefore have to be notified. In studying the temperature charts of these cases I noticed what a large number showed a pyrexia about 100° for seven or eight days and sometimes longer, associated clinically with evidence of uterine infection, mild it

may be, but none the less definite, and therefore capable of developing at any moment into something much more serious. I think it is very significant that 45 per cent. of the cases should show definite evidence of infection of the uterus. Ninety-nine of these cases were discharged alive and apparently well, but it would be instructive to know the number suffering at a later date from such conditions as chronic salpingo-oöphoritis, chronic subinvolution, chronic endometritis, chronic cervical infection and retroversion, with their accompanying chronic ill-health.

CONCLUSIONS AND SUMMARY

The present article is not designed primarily to discuss the details of trial labour. These are sufficiently well known now. But a few positive points in favour of this method of dealing with cases of minor degrees of disproportion cannot be emphasised too much. It cannot be stated too often or too strongly that the uterus, given a chance to act spontaneously, is often capable of remarkable efforts. The character of the pains, as well as the degree of moulding and flexion of the foetal head, are unknown factors at the commencement of any labour. No amount of experience or skill can foretell them before labour starts—so why not be honest and admit that these are unknown factors? A uterus acting spontaneously and well at the appointed time will often accomplish with ease, what it may fail to do, and only do with difficulty, if driven into activity two or three weeks early. The argument that trial labour is unsuitable for domestic midwifery is not really as good as it sounds. It is not the method that is employed, but the patient herself and her unfortunate disability that renders her unsuitable for delivery in a private house, whatever the management of the case may be. And if the doctor argues that he cannot afford the time to bear with the uncertainty these difficult cases often occasion, he is not a suitable person to deal with them. We cannot hope to lower maternal mortality if we allow arguments like that to weigh with us.

In the primigravida, therefore, induction of labour, in my opinion, plays no part in the treatment of minor degrees of disproportion, apart from very exceptional circumstances. The points against induction are : (1) high maternal mortality and morbidity; (2) high foetal mortality which accompanies all methods of surgical induction of labour in primigravidæ.

With multigravidæ the position is very different. In the multigravidæ the method of choice for inducing labour is artificial rupture of membranes. This can be carried out with almost no added risk of sepsis or foetal death; it is often a very wise measure in order to avoid the results of disproportion. In the case of the multigravida one is dealing with a uterus that has become accustomed to childbearing, and with a passage through which the foetus will pass, which has been dilated and stretched once before. Therefore because it is safe to employ artificial rupture of membranes as a means of inducing labour in the parous woman, it is often wise midwifery to do so.

I am indebted to Mr. W. Gilliatt and Mr. A. C. Palmer for permission to publish the results of their cases.

## THE EFFECT OF CHLORAL HYDRATE ON THE HEART

BY STANLEY ALSTEAD, M.D. Liverp., M.R.C.P. Lond.,  
F.R.F.P.S. Glasg.

POLLOK LECTURER IN MATERIA MEDICA AND THERAPEUTICS IN  
THE UNIVERSITY OF GLASGOW; PHYSICIAN TO OUT-PATIENTS  
AT THE WESTERN INFIRMARY OF GLASGOW

CHLORAL HYDRATE was introduced as a hypnotic by Liebreich in 1869, 37 years after its discovery by Liebig. It was a welcome addition to the *materia medica*, which at that time had only opium and morphine as reliable hypnotics.

Gradually an increasing knowledge of the potential toxicity of the drug has made many clinicians reluctant to use it, particularly in the presence of diseases of the cardiovascular system. Nevertheless it is rare to find an experienced practitioner who can recall any serious mishap attributable to this hypnotic. Hutchison<sup>1</sup> mentions the practice of Dr. G. W. Balfour, of Edinburgh, who "used as his 'routine' treatment for pneumonia a mixture containing 10 gr. of Chloral and ℥ 10 of Tincture of Digitalis given every four hours, which he found enabled most of his patients to sleep through their pneumonia." This is also recalled by Stockman<sup>2</sup> who states that no untoward effect from chloral hydrate was seen in these cases. Allan<sup>3</sup> has frequently used this hypnotic in fairly large quantities—e.g., grs. 60 per day—in cases of cardiovascular disease even when accompanied by Cheyne-Stokes respiration, and he has found no evidence of myocardial weakening as a result. Over 20 years ago Gunn<sup>4</sup> declared that he knew of no reliable clinical or experimental evidence to prove that therapeutic doses of chloral hydrate had any depressant action on the heart. Cushny<sup>5</sup> has voiced the same opinion.

Experiments of toxicological interest have often been carried out with chloral hydrate on laboratory animals. Notwithstanding Gunn's observations<sup>4</sup> to the effect that further clinical evidence was required before the odium of a heart-depressant action should be permanently associated with one of the most certain and reliable of hypnotics, there has been remarkably little clinical investigation of this subject. Glaus<sup>6</sup> has reported a series of cases of cardiovascular disease treated with chloral hydrate. In addition to the hypnotic action of the drug the effects upon blood pressure and urinary output were noted. This author sees need for caution in the use of chloral hydrate when there is evidence of congestive cardiac failure. It is clear, however, from the protocols published that the dosage was usually greatly in excess of the B.P. dose (grs. 5–20).

With a few exceptions<sup>7, 8, 9</sup> the standard textbooks of pharmacology and therapeutics continue to give the impression that chloral hydrate is a dangerous hypnotic. Bastedo,<sup>10</sup> arguing from experimental pharmacology, maintains that:

"In good-sized doses it is a circulatory depressant, acting most strikingly to depress the heart-muscle, but also to depress the vaso-constrictor centre and the muscles of the arteries. . . . With only slighter than ordinary therapeutic doses the circulatory depression may supervene, so that the drug becomes distinctly dangerous. There are reports of death from only double the dose to which the patient or habitué had been accustomed. Hence the margin of safety with chloral is a narrow one."

In the English edition of the late Prof. Poulsson's<sup>11</sup> valuable text-book it is stated that chloral "must

be used with great caution in cases of valvular defects and all kinds of cardiac depression (high fever), and also in pulmonary diseases (pneumonia, phthisis, profuse pleuritic exudations)." Clark<sup>12</sup> mentions "a depressant action upon the heart," and adds "the action is exerted by doses but little above the full therapeutic dose." With regard to the effect of chloral upon blood pressure Clark doubts whether the depressing action is greater than that produced by "equivalent doses of the other powerful hypnotics." Whitla<sup>13</sup> pleaded for "great caution" in its use for patients suffering from fatty hearts or atheromatous vessels and went so far as to say that prolonged administration would cause the heart-muscle rapidly to become fatty. An additional warning is given regarding administering chloral hydrate after delirium has lasted several days, "the heart at this time being especially susceptible to its action." Dilling<sup>14</sup> contends that the combined effects of a depressant action on the cardiac muscle and the lowering of blood pressure, which results from vasodilatation accompanied by depression of the vasomotor centre, make chloral unsuitable for use in heart disease.

### CLINICAL TESTS

The present investigation was undertaken in order to assess the value of chloral hydrate as a hypnotic and to note any ill-effects arising directly out of its use. Particular care was taken to record any changes in the cardiac action and in the blood pressure. Observations were made on 55 patients, 6 of whom were children. In 33 cases (60 per cent.) there was clinical evidence of heart disease. Of the remaining 22, though the heart was apparently normal, marked emphysema was found in 7 patients, and 2 others of this group were suffering from acute rheumatism and exophthalmic goitre.

In all but 4 of the patients with cardiac disease, enlargement of the heart was detected clinically. There were 13 with chronic myocarditis, as judged by decrease in the cardiac reserve, alteration of the first heart sound, and hypertrophy of the heart-muscle. Mitral stenosis was the most obvious abnormality in 9 cases and aortic regurgitation occurred either alone or in association with this condition on 4 occasions. Degeneration of the myocardium was attributed to hyperthyroidism in 5 patients. Objective evidence of heart failure—e.g., dyspnoea, cyanosis, and dropsy—accompanied the cardiac lesion in 5 cases. Acute carditis was present in 3 at the time they were receiving chloral hydrate and 1 of these was suffering from subacute infective endocarditis. Conductive disturbances were also represented; 1 of the female patients with a failing myocardium showed electrocardiographic evidence of bundle-branch block, and in an unusual case of hyperthyroidism a succession of cardiac irregularities, including complete dissociation and auricular flutter, were recorded before the administration of chloral hydrate.

Other therapeutic measures were not withheld during the investigation. Thus iodine was given in 2 cases of Graves's disease and probably accounted for a fall in the pulse-rate of these patients. Salicylates were prescribed as usual in rheumatic fever, protein shock therapy with *Bacillus typhosus* was used in rheumatoid arthritis, and injections of bismuth were continued in cases of tertiary syphilis. In 10 patients the administration of digitalis may have modified the action of the heart. The quantity of digitalis and the time when it was given in relation to beginning chloral hydrate therapy make it unlikely that this was of any significance in at least 4 of these cases.

*Dosage.*—It was not found necessary to exceed the official dose (B.P. grs. 20) to produce a hypnotic

effect. In order thoroughly to test the possible toxic action of such quantities without prolonging the investigation unduly for the patient, two doses of grs. 10 each were given during the day and one of grs. 20 at night. This was continued for 7-10 days in most cases, about grs. 350 of chloral hydrate being given during this time. The well-known potency of this hypnotic was very evident. Sleep was induced within half an hour and lasted until the patients were wakened some seven or eight hours later. One man (a sailor) described the effect in characteristic fashion when he said that after his evening dose he was soon "dead to the world" and he knew nothing more until breakfast-time the following morning. After his meal he received a further grs. 10 of chloral hydrate and, he declared, this sent him off again, so that he was awake only a few hours out of the 24. Drowsiness was often so persistent that it was sometimes difficult to rouse patients sufficiently to take their meals. This degree of hypnosis seemed to be as much as would ever be required under clinical conditions. It is not suggested that excessive drowsiness on waking is characteristic of chloral. On the contrary, in the cases studied drowsiness during the day was clearly due to the doses of the drug given in the daytime; for when these were omitted, only the hypnotic action of the evening dose was observed.

#### ILL-EFFECTS

**Stomach.**—Chloral hydrate is known to be irritating to the stomach unless well diluted with water. For this reason its use is generally avoided in patients suffering from gastro-intestinal disturbances. In the present series 6 of the patients (11 per cent.) complained of nausea and vomiting attributable wholly or in part to this hypnotic. On two occasions the stomach was probably irritable owing to congestive heart failure and in a case of uræmia nausea was already troublesome before chloral hydrate was given. One man who was being treated for hyperchlorhydria (Case L) complained that his gastric discomfort was intensified. The stomach was certainly normal in the remaining patient and all disagreeable symptoms ceased on further dilution of the drug with weak peppermint-water.

**Skin.**—The eruptions that are sometimes described as a result of giving chloral hydrate did not occur once in this group of 55 patients. Three patients, however, suffered from smarting or burning of the edges of the eyelids. The conjunctivæ were injected and excessive lacrymation was a source of annoyance. In another patient the eyes were obviously suffused but no complaint was made. This complication is mentioned by Ghosh.<sup>15</sup>

**Respiration.**—During sleep the respiratory rate was diminished, but not more than might occur in natural sleep, and evidence of excessive medullary depression—e.g., cyanosis, irregularity of breathing, and so forth—was never seen.

**Tolerance.**—A neurotic woman suffering from Graves's disease noticed that the hypnotic action of the drug became very much less after about seven days. No other instance of tolerance was seen.

#### EFFECTS ON CIRCULATION

**Heart.**—Examinations of the heart were made before, during, and after giving chloral hydrate. Special attention was paid to changes which might be regarded as indicating depression of the myocardium, such as (a) changes in rate or rhythm, (b) alteration in the position of the apex-beat and the character of the cardiac thrust, (c) weakening

of the heart sounds, especially the first sound at the apex, (d) the appearance of bruits, or alteration in the character of pre-existing murmurs, and (e) evidence of diminished cardiac reserve.

In a case of disseminated sclerosis (Case A) slight softening of the heart sounds was noted towards the end of the period of observation. There was no other abnormality in the heart and except for drowsiness the patient was unaware of any change in his general condition. The electrocardiogram before and after giving chloral hydrate was normal and unaltered by the drug. The blood pressure changed from 125/70 to 110/70 mm. Hg but the pulse-rate remained at about 75 throughout. These findings applied also in Case B, but here the blood pressure increased from 100/55 to 115/65 mm. Hg and early slurring of Q R S was seen subsequently in lead II. of the electrocardiogram.

In Case C the volume of the first heart sound, which was diminished at first owing to cardiac failure, gradually increased as the patient's condition responded to rest in bed and digitalisation, despite a total of grs. 390 of chloral hydrate given during 11 days. The blood pressure also increased from 139/95 to 145/100 mm. Hg. Though the electrocardiogram showed the early effects of digitalis there was no alteration in the final record.

The cardiac thrust became more forcible in a boy known to be suffering from rheumatic carditis. He received chloral hydrate for 19 days but the change in physical signs was consistent with an advancing rheumatic lesion rather than depression caused by the hypnotic. The blood pressure changed from 105/50 to 95/65 while the pulse-rate was unaltered. The P-R interval in the electrocardiogram measured 0.22 sec. before and after giving the drug.

In Case D the abnormal accentuation of the first sound which accompanied left-sided hypertrophy was considerably diminished after grs. 150 of chloral hydrate, and a systolic bruit previously heard at the apex was no longer audible. The blood pressure fell from 150/70 to 120/60. Though the cardiac action was apparently regular on physical examination the first electrocardiogram showed auricular fibrillation. The record obtained after the chloral hydrate had been stopped was normal except that P-R measured 0.2 sec. and the voltage was low. It was impossible to continue with the investigation as the patient wished to go home; this she was able to do without developing shortness of breath, &c., on ordinary exertion.

In Case E an aortic diastolic murmur was not so easily heard after the patient had received a total of grs. 630 of chloral hydrate over a period of 15 days, otherwise the physical signs in the heart were unchanged.

**Pulse-rate.**—The trend of the pulse-rate was noted carefully throughout the investigation but sudden and temporary variations were ignored. In 43 patients (78 per cent.) there was change in heart-rate. In 8 cases (14 per cent.) the rate diminished appreciably, but circumstances other than the use of chloral hydrate would account for the slowing of the heart in at least 6 of these patients, 3 of whom were receiving digitalis, 1 salicylates, and 1 iodine, while it was known that the pulse-rate in another was variable owing to heart-block. In only 2 patients could the slowing of the pulse-rate be attributed to chloral hydrate and in both instances the fall was to the extent of 10 beats per minute—i.e., from 110 to 100, and from 80 to 70 respectively. Neither of these patients showed any deterioration in physical signs on re-examination of the heart.

A slight degree of tachycardia was observed in 4 patients. Pyrexia, progressing uræmia, and infective endocarditis were regarded as accounting for this in 3 of the cases and in none did the increase in rate exceed ten beats per minute.

**Blood pressure.**—Readings were taken with a baumanometer within two hours of giving the morning dose of chloral hydrate. On every occasion

the right arm was used and the patient was in the recumbent posture. It was often necessary to rouse patients from sleep in order to attach the apparatus. In 13 cases (23 per cent.) there was no change in the blood pressure. A fall in pressure was noted in 29 patients (53 per cent.); with a few notable exceptions, however, the decrease was not very considerable. In 13 patients (23 per cent.) there was

TABLE I  
*The Effect upon Blood Pressure*

—	Fall of blood pressure (systolic).								Increase of blood pressure (systolic).			
	5	10	15	20	25	30	35	40	5	10	15	30
Mm. Hg ..												
Number of patients ..	14	5	2	1	2	1	2	1	4	6	2	1
Percentage of series ..	25.5	9.1	3.6	1.8	3.6	1.8	3.6	1.8	7.3	11	3.6	1.8

actually an increase of blood pressure between 5 and 30 mm. Hg following the administration of chloral hydrate (Table I.). The original ratio between the systolic and diastolic blood pressures tended to be maintained in 40 of the 55 patients (73 per cent.). In 10 cases (18 per cent.) in which the systolic pressure was raised the diastolic reading was unchanged. Five patients (9 per cent.) showed alterations of 5–15 mm. Hg in the diastolic pressure while the systolic pressure moved in an opposite direction.

The way in which these changes in blood pressure were distributed between the two groups of patients—(1) those with heart disease, and (2) those with normal hearts—is shown in Table II.

TABLE II  
*Comparison of Two Groups of Patients*

Patients with heart disease.				Patients with normal hearts.	
Blood pressure (systolic).	Number of patients.	Percentage of group.	Number of patients.	Percentage of group.	
Unchanged .. ..	8	24	5	22	
Lowered .. ..	15	45	14	61	
Raised .. ..	10	30	3	14	

The condition of 3 patients calls for special mention.

*Case D* (chronic myocarditis).—There was a decrease of 30 mm. Hg in the systolic pressure but no apparent deterioration in the action of the heart occurred. On the contrary, the disappearance of fibrillation and the return of a normal rhythm may be regarded as evidence of a favourable response to other measures notwithstanding the simultaneous administration of chloral hydrate.

*Case F* (chronic myocarditis).—During the period of observation signs of cardiac failure disappeared though chloral hydrate was being given. On resuming work, however, signs of failure returned and with the fall in blood pressure (35 mm. Hg) the T-wave in lead III. of the electrocardiogram became deeply inverted. These circumstances hardly justify incriminating chloral hydrate as the chief cause of the decrease in blood pressure.

*Case G*.—For two years this patient had suffered from palpitation accompanied by attacks of giddiness. The transient irregularity turned out to be auricular fibrillation and giddiness was attributed to fluctuations in the blood pressure likely to occur under these conditions. The electrocardiogram showed that a paroxysm of fibrillation

immediately preceded the final reading of the blood pressure.

*Electrocardiogram*.—As might be expected from the diseases enumerated many of the electrocardiograms were abnormal from the beginning. Significant changes were observed in 14 patients (25 per cent.) during the administration of chloral hydrate. The alterations did not always indicate deterioration of the heart; sometimes, indeed, the reverse was true. Thus in 1 patient, though the myocardium had been severely affected and grave interference with conduction was evident in the electrocardiographic records, auriculo-ventricular rhythm was resumed despite medication with chloral hydrate. Similarly, on two occasions (Cases H and D) auricular fibrillation disappeared while the hypnotic was being given in therapeutic doses. Serial records in Cases I and J showed that chloral hydrate did not interfere with the usual stages of recovery of the heart from digitalisation.

TABLE III  
*Changes Indicating Depression of Conductivity*

Case	Heart-rate before chloral	P-R interval (secs.)	Heart-rate after chloral	P-R interval (secs.)	Remarks.
K	88	0.16	116	0.18	Choreic movements again present at last exam.
L	84	0.20	82	0.22	Clinically normal heart.
M	72	0.24	78	0.26	
N	84	0.28	86	0.30	Bundle-branch block.

While it seemed probable that the prolongation of the P-R interval was due to chloral hydrate in the last 3 patients, in Case K tachycardia actually resulted from a recurrence of chorea and the slight change in the electrocardiogram also could reasonably be attributed to this, especially as three intermediate records showed no change. Shortening of the P-R interval was noted in Case O where it measured 0.22 sec. when the heart-rate was 88, whereas after chloral hydrate it diminished to 0.2 sec. with a slightly greater heart-rate of 92 per minute. Early slurring of QRS developed in 1 patient but the significance of this is doubtful as the same feature disappeared from the records of 2 others in the same circumstances. Bundle-branch block in Case N became more definite under chloral hydrate—i.e., inversion of the T-wave in lead I. was more pronounced. Separation of the P- and T-waves contributed to this appearance.

#### DISCUSSION

That chloral hydrate in ordinary doses is a remarkably effective hypnotic almost entirely free from the disadvantages of tolerance and habit formation is confirmed by this investigation. On the whole it seems that the drug is best avoided in the presence of gastro-intestinal irritation, but this drawback can be practically eliminated by diluting sufficiently with water. Smarting of the eyelids and lacrymation were troublesome in about 5 per cent. of the patients under observation. This occurred only after several days during which the dosage had been frequent and substantial. Under ordinary clinical conditions, when a single dose is given every night for a week or two, it is reasonable to assume that these ocular complications would be less likely to develop.

Physical examination of the heart yielded no unequivocal evidence of weakening of the cardiac

action by chloral hydrate. Only 3 patients (Cases A, B, and D) appear to admit of some discussion on this point. From the clinical data it will be seen, however, that though some slight abnormality is mentioned the results of further investigation of the cardiovascular system were inconsistent with cardiac damage. On the other hand, clinical evidence of improvement in the action of the heart (attributable to rest in bed, &c.) was seen in 2 cases. No significant changes occurred in the heart-rate.

About half of the patients showed some fall in blood pressure. In the great majority of these the decrease did not exceed 15 mm. Hg and as there was no alteration in the condition of the heart the change in blood pressure was regarded as being consistent with prolonged periods of sleep and almost continuous drowsiness. In the few cases where the blood pressure was depressed more than 15 mm. Hg conditions other than the administration of the hypnotic were regarded as being the main causes. Nearly a quarter of the patients were found to have an increased blood pressure after taking chloral hydrate. It is difficult to say what may be the exact significance of these findings, but they certainly discount to some extent (though not entirely) the results which show the opposite effect on the blood pressure. The figures in Table III. do not lend support to the view that chloral hydrate is particularly detrimental in the presence of heart disease.

In Cases L, M, and N (Table III.) slightly delayed conduction was noticed. These must be compared with Case O in which the findings were exactly the reverse. These changes are regarded as being too trivial to be of clinical importance.

#### CONCLUSION

Chloral hydrate in therapeutic doses has no harmful effect upon the heart. When the blood pressure is lowered during chloral hydrate administration the effect is not much greater than occurs in natural sleep.

I am indebted to Dr. John Gracie, visiting physician to the Western Infirmary, for permission to publish this work, and to Sister J. R. Thompson for her willing coöperation.

FOLKESTONE HOSPITAL.—Extensions to this hospital, at a cost of £85,000, are contemplated. The institution would then have 165 beds, 16 maternity beds, 25 private wards, a new children's ward, and a pathological department. Some funds are in hand, but £60,000 will have to be raised.

## ON THE POSSIBLE TRANSMISSION OF HÆMOLYTIC STREPTOCOCCI BY DUST

BY ELIZABETH WHITE, M.B. Lond., D.P.H.

ASSISTANT BACTERIOLOGIST AT THE BERNHARD BARON MEMORIAL  
RESEARCH LABORATORIES, QUEEN CHARLOTTE'S  
HOSPITAL, ISOLATION BLOCK

RECENT attempts to trace the source of puerperal infections (D. C. Colebrook, 1935)<sup>1</sup> have suggested very strongly that in the majority of cases—at least 80 per cent.—the streptococci had been conveyed to the genital tract from the nose or throat of the mother herself, or of someone in contact with her. In a minority of cases no such probable source was found, and the question arises whether in these cases the hæmolytic streptococci may not have reached the genital tract by the agency of air-borne particles. This possibility seems the more likely in view of the recent finding by Cruickshank (1935)<sup>2</sup> that the air of wards in which patients suffering from burns were nursed frequently yielded fairly abundant cultures of hæmolytic streptococci, whereas the air of the medical wards in the same hospital yielded none, and that of the surgical wards only a few colonies. In private houses at the time of a confinement there must sometimes be persons with septic foci infected by these streptococci, such as children with otorrhœa or impetigo, or adults with infected wounds who, although not in close contact with the mother during labour or in the puerperium, may have contaminated the dust, which in turn may originate a puerperal infection. This possibility must be increased where there is overcrowding.

In Queen Charlotte's Isolation Hospital for puerperal fever all cases are admitted into single bed wards. In a considerable number the hæmolytic streptococcus is the infecting organism. It was decided in such cases to investigate whether the dust in the ward became contaminated with hæmolytic streptococci and, if so, to what degree and for what period. By the examination of such special cases some further knowledge of the possibility of infection by dust might be obtained.

#### INVESTIGATIONS

Tests on the air and the dust in the wards were carried out between the third and the sixth day after admission as follows.

Two horse blood-agar plates were exposed by the night nurse after she had settled the patient for the night. One was placed on the trolley about 1½ yards from the foot of the bed and the other on the locker beside the bed. These were closed by the nurse when she woke the patient in the morning and were therefore exposed for about six hours. Two more plates were exposed in the same places by the nurse who made the first perineal toilet of the patient. These were left open while she was doing this and then closed. They were open for about twenty minutes to half an hour. There would be more movement in the ward during this period than during the night.

While the ward was being swept and polished two more plates were opened, one being placed on the trolley at the foot of the bed, as in the other cases, and the other on the floor. These were exposed for about twenty minutes and were in a more dusty atmosphere than the others.

The six plates were incubated over-night in anaerobic conditions, because this helps to keep down the saprophytic organisms and also shows up the hæmolytic streptococcus colonies more clearly (R. M. Fry, 1933).<sup>3</sup> The number of the latter were counted and one or more subcultured and tested for soluble hæmolysin production. The total number of hæmolytic streptococcus colonies on all these six plates was taken as an "index of contamination" of the ward.

RESULTS

It was found that the hæmolytic streptococcus occurs in the dust of single bed wards where cases infected with this organism are nursed, and not to anything like the same extent in the wards of patients with sepsis due to other organisms. This is shown clearly in Table I. The index of contamination for the six control cases is low, while that of the other cases is much higher in general.

TABLE I

Index of contamination of ward.	0	1-2	3-5	6-10	11-20	21-50	51-100	Over 100
Cases infected with— Hæmolytic strep. . .	0	2	3	5	3	9	3	2
Other organisms . . .	3	3	0	0	0	0	0	0

With regard to the occasional presence of hæmolytic streptococci in the dust of a ward used as a control, there are two possibilities. The organism might have been left by a previous occupant, or it might have been carried there on the broom, or on the shoes or clothing of the staff, as the five single bed wards on each floor open along the same side of one corridor. In one case the latter possibility was considered likely, as the hæmolytic streptococcus was found to be the same type serologically as the infecting strain of a case of puerperal scarlet fever with a high index of contamination on the same floor.

A similar result to that shown above was obtained from experiments made in two wards of five beds each. In one of these were convalescent cases infected with hæmolytic streptococci, and in the other, patients recovering from other infections.

Two plates were exposed in the middle of each ward during sweeping, one on the floor and the other on the table. Their incubation and further examination was as previously described. The index of contamination, calculated as the total number of colonies on the two plates in this experiment, was 55 in the first ward and only five in the second. (The control ward, i.e., with patients not infected by hæmolytic streptococci had, a week or two previous to the experiment, housed some patients who were convalescent from an infection with that organism, and had not been disinfected since their discharge.)

The twenty-seven cases infected with hæmolytic streptococcus, the dust of whose wards was tested, were not selected in any particular way. Their clinical condition varied from a mild localised infection of the genital tract to a local infection plus pelvic cellulitis, general peritonitis, puerperal scarlet fever, and septicaemia. In a proportion of all these types of infection the hæmolytic streptococcus was isolated from the respiratory tract, either the throat, nose, or naso-pharynx. While the number of cases in each class is too small to allow any definite conclusions to be drawn, there is no evidence that the degree of contamination of the dust is correlated with the severity of the clinical condition or infection of the respiratory tract. The data for the twenty-seven cases is classified in Table II. according to their clinical condition. It is of interest to note that in only two cases was the amount of lochia in excess of the normal. It was found, however, that in two cases that were examined in greater detail the index of contamination did decrease as the patient recovered. The cases examined were two of the puerperal scarlet fever cases of Table II. The six plates, from which the index of contamination was found, were exposed at intervals of twenty-four to forty-eight hours

during the whole of the patients' stay in hospital—thirty-one days in one case and seventeen days in the other. In both, the hæmolytic streptococcus persisted in the cervix until the day of discharge.

TABLE II

Type of case.	Source of hæmolytic streptococcus		Cases.	Index of contamination for each case.
	Cervix.	Resp. tract.		
Mild local . . . . .	+	..	4	10, 16, 29, 66, 12, 84
Infection . . . . .	+	+	2	
Severe local . . . . .	+	..	3	4, 6, 7
Infection . . . . .	+	+	2	3, 13
Mild local and pelvic . . . . .	+	..	1	4
Severe local . . . . .	+	..	2	23, 33
and pelvic infection . . . . .	+	+	5	2, 2, 23, 25, 78
Puerperal scarlet fever . . . . .	+	..	1	6 (a)
2 cases with septicaemia . . . . .	+	+	4	29 (a), 32, 271, 981 (a, b)
General peritonitis (opened and drained) . . . . .	+	+	1	20 (a)
Septicaemia . . . . .	+	..	2	10, 43 (b)

(a) = patient died. (b) = lochia in excess of normal.

The decreasing index of contamination is shown in the Figure.

It is interesting to notice that Mrs. C. developed tonsillitis on the fourteenth day after admission, and a culture from the throat showed a nearly pure growth of hæmolytic streptococcus, serologically identical with the cervical strain. The figure shows that there was a slight increase in the index of contamination at this time, though whether this is

Daily variation of index of contamination.

caused by the tonsillitis it is impossible to say. The experiment also shows that when this patient was out of bed, and therefore more likely to disturb any dust, there was a marked rise in the number of colonies.

VIABILITY OF THE HÆMOLYTIC STREPTOCOCCUS IN DUST

It is of some importance to know if the hæmolytic streptococcus will live in the dust of the room when the source of contamination is removed. Two experiments were made to investigate this.

In the first, two plates were exposed for six hours in a room immediately after the patient had died and the body been removed to the mortuary. The windows were shut and the doors locked so that there were no currents of air, and the bedding, &c., was left in situ. Plates were exposed on three more occasions with the same conditions and finally while the floor was swept and the bedding shaken. The results are shown in Table III.

TABLE III

Date.	Index of contamination.	Remarks.
19/10/35	320	Two days before death.
21/10/35	28	After removal of body.
22/10/35 A.M.	0	Room undisturbed.
22/10/35 P.M.	0	" "
23/10/35 A.M.	0	" "
23/10/35	90	While sweeping for 15 minutes.

In the second experiment, after the original test, the patient was transferred to another ward. At various intervals two plates were exposed while the bed, which she had occupied, was stripped and remade and the dust swept from one corner of the room to the other. The results obtained are shown in Table IV.

TABLE IV

Date.	Index of contamination.	Remarks.
5/2/36	5	Patient in room. Routine sweeping.
6/2/36	42	No patient. Room swept and bed remade.
7/2/36	36	" "
8/2/36	21	" "
10/2/36	70	" "

There seems to be no doubt that the streptococcus will live in the dust for several days and that its presence can be detected more readily when the air of the room has been disturbed.

Dr. L. Colebrook has kindly allowed me to quote an experiment carried out by him on the same subject. A broth culture of hæmolytic streptococcus was sprayed into a dusty cupboard. At intervals the dust was raised and allowed to settle on horse-blood agar plates. After incubation, hæmolytic colonies were subcultured and tested in the way described above. It was found that the organisms lived for ten weeks. The experiment is still continuing. Some of the contaminated dust was also kept in a Petri dish exposed to light and under these conditions they also lived for ten weeks.

#### DISINFECTION OF ROOMS CONTAMINATED WITH HÆMOLYTIC STREPTOCOCCI

Since it was found that hæmolytic streptococcus can live in dust for many days or weeks, tests were made of the efficacy of the method employed for disinfecting the rooms after they were vacated by the patient. The procedure was to spray the room, using an Enot's spray, with half to one pint of commercial formalin (40 per cent. formaldehyde) either undiluted or diluted with one or two parts of water. The room was sealed and left for at least twenty-four hours. The windows were then opened, and when the room was sufficiently aired it was thoroughly cleaned in the usual way. The two blood-agar plates were exposed for half an hour during this cleaning. The 40 per cent. formaldehyde was strong enough to kill the hæmolytic streptococcus, and it was noticed that very few saprophytic organisms grew on the plates. With the weaker solutions hæmolytic streptococcus was found to persist on two of the five occasions on which this test was made, and the growth of saprophytes was much greater.

#### IDENTIFICATION OF THE DUST STRAINS

Since hæmolytic streptococcus is found in the wards occupied by patients infected with this organism and not to any extent in other wards, it suggests that the patient is the source of the organism. This was confirmed by the serological examination of the patient's infecting strain and that recovered from the dust of her ward. Dr. Dora Colebrook very kindly undertook these tests. The method employed was the direct slide agglutination with absorbed sera by the technique introduced by Griffith (1935).<sup>4</sup> The details of the test, its interpretation, and any technical difficulties that may arise have been fully dealt with by Dr. Colebrook in her paper (1935).<sup>1</sup>

Out of twenty-seven cases the infecting strain was typed in 18. The remainder may not have been one of Griffith's types, or the suspensions tested may have been insensitive or were unusable. Among these 18 cases there were 12 types of streptococcus, and not more than 3 of any one type. This was fortunate as it enabled the strain from the dust to be definitely associated with one patient. The strains from a few only of the plates exposed for each patient were tested, as the task of examining every one appeared an unnecessary labour. The results were as follows (Table V).

TABLE V

Number of dust plates of 18 typed cases from which hæmolytic streptococci were isolated	.. ..	199
Dust strains tested	.. ..	51
Dust strains the same as the corresponding infecting strain	.. ..	39

Those obtained from a room after fumigation were in each case the same as the infecting strain of the patient who had occupied that room. On three occasions two types of hæmolytic streptococcus were isolated from one plate. One of these was the patient's own type and the other that of the previous occupant who had been removed to the convalescent ward a week before. As mentioned above a strain recovered from the dust of a ward occupied by a control case was the same as the infecting strain of a case of puerperal scarlet fever, with a high index of contamination, who was nursed on the same floor but in a different ward.

#### AN ACUTE THROAT INFECTION ATTRIBUTABLE TO DUST

With regard to the experiments set out in Table IV, it is of interest that the person responsible for making the bed and sweeping the floor, in spite of wearing a mask consisting of two layers of muslin with paper in between, over nose and mouth, contracted an acute pharyngitis and adenitis due to a hæmolytic streptococcus on Feb. 10th, 1936. This organism was serologically identical with that grown from the dust, and from the cervix of the patient who had been in the ward. There was no direct contact with the patient but only with the dust after the patient had been removed to another ward. Here apparently is a clear case of infection by dust.

In contrast to this experience, it may be mentioned that two nurses who spent several hours each day in the room of a dying patient with an index of contamination of 981 did not become carriers or contract an infection. They wore similar masks to that described above all the time they were in the ward.

An experiment made by Dr. L. Colebrook has shown that hæmolytic streptococci maintain their mouse virulence in dust undiminished for 25 days.

## SUMMARY

The dust of twenty-seven single bed wards housing patients who are discharging hæmolytic streptococci was always contaminated with that organism, and in most cases the strain isolated from the dust was proved to be identical with that infecting the patient.

The dust of similar wards housing patients infected with other organisms seldom yielded hæmolytic streptococci, and then only very scanty growths.

Spraying with formalin (40 per cent. formaldehyde) destroyed the hæmolytic streptococcus in rooms contaminated with that organism.

A case is reported in which exposure to dust carrying hæmolytic streptococcus was almost certainly responsible for an acute pharyngitis.

Although no opportunity has occurred for investigating the point, it would seem unlikely in view of the experiments reported by Dr. L. Colebrook (1933)<sup>5</sup> that a healthy throat carrier of hæmolytic streptococcus creates a zone of streptococcus-carrying particles around himself.

I wish to express my thanks to Dr. L. Colebrook for his encouragement and interest in this work; to Dr. Dora Colebrook for undertaking the serological investigations described; to the resident medical officer, Dr. M. Kenny, and to the sisters and nursing staff of the hospital for their willing coöperation.

## THE TREATMENT OF PHLEBITIS IN VARICOSE VEINS \*

BY H. I. BIEGELEISEN, M.D.

CHIEF, VARICOSE VEIN CLINIC, STUYVESANT POLYCLINIC,  
NEW YORK CITY

THE conservative treatment of phlebitis in varicose veins has proved unsatisfactory and the purpose of this paper is to present a new method of treating this rebellious disorder, which so often terminates in a permanently damaged extremity.

Varicophlebitis differs from ordinary phlebitis because the blood stream that feeds it is stagnant. One would therefore expect, as indeed one finds, that the activity of the inflammatory process is related to the speed of the blood stream. In other words, subacute or chronic infections are the rule; and quiet latent infections, which may be symptomless, occur frequently. Occasionally an acute inflammation is met with; it may follow the establishment of a septic focus elsewhere or be produced by severe trauma. This acute phlebitis tends to subside and then falls into the large group of subacute, chronic, and latent infections which will now be considered.

Phlebitis in varicose veins is extremely common (Fig. 1). At least half of all varicosed extremities have infected veins. This startling fact was first pointed out by de Takats,<sup>1</sup> who actually cultured bacteria from isolated vein segments that he excised in a general group of varicose vein cases; half of these developed a bacterial growth in 5-10 days. These bacteria were slow-growing and of low virulence. As I recently pointed out,<sup>2</sup> clinically one

meets with unexpected "flare-ups" following the injection treatment which have an incubation period resembling that of the bacteria in de Takats's cultures. It is apparent from this experimental and clinical evidence that phlebitis is often present in a quiescent state and may be innocently excited by the inexperienced operator.

The sedimentation-rate, which I suggested in 1934 as the best diagnostic sign of phlebitis, has been used by me consistently since then with the result that my original confidence in this test has been strengthened. With its assistance, after proper evaluation, the injection treatment of phlebitis is made safer and more controllable.

What has been done in the past for phlebitis of varicose veins? With the establishment of the diagnosis, the patient was put to bed, the extremity elevated, and cold applications applied locally. After a variable uncertain period the patient was allowed up and the phlebitic extremity treated in a variety of fashions. Elastic supports, X ray therapy, and thermal baths were some of the procedures used. A few bolder spirits advised injections after healing was completed, setting arbitrary time limits of six months to two years for this to take place. The whole picture was a confused and timid one, with the result that few patients escaped permanent leg damage. The old conservatism was due to two reasons: the first was the fear of injecting an inflamed vein and thereby spreading the process, and the second the dread of embolism.

The modern method of treating inflamed varicose veins is to sclerose them as soon as possible. This newer form of attack is rationally sound and is based on the following premises: (1) phlebitis in varicose veins rarely heals spontaneously; (2) the danger of embolism is greater in the untreated cases; (3) temporising means permanent lymphatic and tissue damage; and (4) sclerosing injections can safely occlude the dilated infected vessels.

The chronicity of varicophlebitis has been stressed before. It is, however, not generally recognised that evidences of infection may be present many years after the apparent subsidence of acute phlebitic infections. I have seen many patients in whom traces of phlebitis persisted 5-20 years after the original attack. The following is a short history of such a case.

Mrs. A., aged 52, had had varicose veins for eighteen

FIG. 1.—Phlebitic varicose veins: no tenderness, thrombosis, or hyperthermia. Varicose ulcer present. Sedimentation-rate 20 minutes.

\* Read before the East Side Clinical Society, New York, 1935.

years. The first attack of acute phlebitis ten years ago was treated by rest in bed for two weeks. A second attack of phlebitis occurred eight years ago. In her last attack she was in bed three weeks; spontaneous tender thromboses were noted, and a mild state of lymphœdema with fibrosis was present on both legs. The sedimentation-

of an ordinary varicosity which does not migrate and appears in 1-3 days after a treatment.

The injection method should be so gauged as to avoid flare-ups. A careful technique must be followed. The only patients excluded from treatment are those with the relatively rare acute widespread processes. In these occasional cases treatment is delayed until the phlebitis is subacute or chronic. The vast majority of cases of phlebitis are immediately amenable to the following plan.

#### TECHNIQUE AND RESULTS

After a careful history and physical examination, the sedimentation-rate is taken by the Linzenmeier technique using 5 per cent. sodium citrate. The interpretation of this test is important. In the absence of any other infection, a rapid rate points to phlebitis. The latency of the infection is roughly proportional to the sedimentation time, as follows:—

- Below 30 mins.—an active infection.
- 30-60 mins.—a fairly active infection.
- 60-90 mins.—a probable latent infection.
- Over 120 mins.—probable absence of infection.

The initial injection should always be a mild one. I begin with 1 c.cm. of 60 per cent. invertose solution in all cases with a sedimentation-rate over 30 mins. With a more rapid rate, one should start with normal saline solution or 2 minims (0.1 c.cm.) of invertose. It is dangerous to begin any treatment with quinine or other strong irritants, no matter what the sedimentation-rate may be. The succeeding injections are gradually made stronger, endeavouring at all times to keep the reactions below the flare-up point. The strength of action may be increased by using larger quantities of the same irritant or by substituting the next stronger irritant in the series. The three most generally used solutions in the order of increasing sclerosing action are: invertose, sodium morrhuate, and quinine.

It will be found that the reactions produced even by careful treatment will be different from those obtained in uninfected veins. In phlebotic vessels they will often be delayed, depending upon the incubation period of the bacteria involved. Slight migration of the response may be noted and healing is slower than usual. Sometimes a double reaction will be noted. The initial chemical irritation may subside, to be followed by a second phlebotic reaction a week later. It is therefore important not to treat these patients more often than once a week.

The reactions following injection become more normal as the case progresses until no signs of phlebotis remain. All the cases in my series were finished with strong irritants. After the fifth injection, in most instances, a fairly strong solution like sodium morrhuate 5 per cent. was well borne. In 60 per cent. of the cases quinine was used for the final injections with good results. Apparently the successive mild phlebotic responses to chemical irritation increased the patient's resistance to his own infection. In this connexion it is interesting to note that Du Laurier<sup>5</sup> in 1931 advocated vaccine therapy as a preliminary to the injection treatment of phlebotis. The 300 patients that have been injected by me under this plan of treatment have all gone on to an uneventful cure. I feel sure that phlebotis should no longer be considered a contra-indication to the injection treatment of varicose veins.

#### CONCLUSIONS

- (1) Phlebotis in a subacute, chronic, or latent form complicates about 50 per cent. of cases of varicose

FIG. 2.—Bilateral lymphœdema resulting from untreated varicophlebitis. The pigmented areas are hard and tender.

rate was 45 minutes. There was latent phlebotis as a result of the original acute infection eight and ten years ago. Injection treatment was uneventfully successful.

In other patients, a puerperal or post-operative varicophlebotis which has been treated conservatively is the starting-point of a chronic infection which often persists indefinitely although the original insult dates back many years. It is evident, therefore, that time does not cure these cases. Delay in treatment on this score is unwarranted and is more dangerous than careful obliteration of the infected varices. It is a common experience to find flare-ups due to trauma of phlebotic dilatations. There is also the danger of an acute activation following a general infection or the establishment of a new septic focus. These recrudescences may cause the formation of friable clots and become a dangerous source of emboli. Furthermore, any future obstetrical or operative procedure becomes a hazardous affair in the presence of infected veins. Quiet careful obliteration, in the manner to be described, effectively removes these potential sources of embolism.

Lymphœdema, to some degree, invariably complicates varicophlebotis as time goes on, and once it has been established it tends to persist.<sup>3</sup> The lymphatic damage goes on to fibrosis and ulceration, causing deformity and disability. One should consequently aim to stop the spread of infection into the lymphatic system before this permanent damage occurs (Fig. 2).

That sclerosing injections can be safely used has been my experience in 300 cases. Working independently, Delater and Chailly<sup>4</sup> in 1934 reported on their method of arresting active varicose phlebotis by the injection of sclerosing fluids. They did not present any definite technique, merely advising the usual injections. This is incorrect as will be pointed out later.

In order to safely treat phlebotis in varicose veins one must understand the flare-up reaction following an injection. This inflammatory phlebotic response points to the existence of an active phlebotis. It is identified by an incubation period of 5-10 days and a tendency to migrate along the course of a vein. This is in contrast to the non-phlebotic response

veins. (2) In such cases it is the starting-point of a pernicious cycle which permanently damages the superficial tissues of the extremity. (3) It can and should be treated early by a special injection technique. (4) The sedimentation-rate is useful as a guide for treatment. (5) By this method 300 cases have been treated with uniformly good results.

TREATMENT OF TUBERCULOUS CERVICAL GLANDS

BY BRIAN C. THOMPSON, M.D. Camb.

ASSISTANT TUBERCULOSIS OFFICER, DURHAM COUNTY COUNCIL

THOUGH cervical-gland tuberculosis is steadily becoming less frequent<sup>9</sup> it remains a relatively common condition, particularly in certain parts of this country.<sup>8</sup> On my dispensary register for 1934 were 978 patients suffering from all forms of tuberculosis, drawn from the north-eastern district of the county of Durham, on the south bank of the Tyne, and 195 of these (20 per cent.) were cervical-gland cases. Yet despite this frequency and the fact that most practitioners must encounter the disease from time to time, medical text-books as a whole<sup>2 4 6 8 10 11 13-16</sup> appear to have no unanimous opinion about treatment, though methods in common use are variously recommended. To test certain of these methods I have applied them proportionately to a total of 277 personal cases, and by comparing the results I have evolved a routine for dealing with any given case.

METHODS OF TREATMENT

*Sanatorium.*—Pure sanatorium routine, under ideal conditions of hygiene and climate, is regarded as preliminary treatment for all cases by several authorities.<sup>2 4 6 7 10 13-16</sup> I am opposed to it primarily on grounds of expense and inexpediency. For any State-aided tuberculosis scheme, the cost of providing sanatorium accommodation for such numbers as I have quoted, or, alternatively, the exclusion for their benefit of sufferers from other forms of tuberculosis, could only be justified if cervical-gland patients were not able to be as effectively cared for at home. In view of results obtained by ambulant methods I have satisfied myself on this point, and now admit to institutions only patients with certain complications, which form a very small percentage of the whole.

*Iodides.*—The glands had not reached the stage of gross caseation in 64 cases, and these were given syrup. ferri iod. (B.P.) in full doses over periods ranging from two months to three years, those reacting favourably being afterwards kept under observation for at least one year. It was found that complete clinical disappearance occurred in only 4 patients, and then in glands which had never progressed beyond the earliest stage of lymphoid enlargement. It appears that complete resolution is seldom, if ever, attained under this treatment, and that the optimum result to be hoped for is defined by shrinkage, mobility, and firmness, indicating progressive fibrosis and showing later to X ray the dense shadows of calcium deposition. This must constitute a "cure,"

so far as that term may be applied to any tuberculous focus. The continued presence of living tubercle bacilli in such latent foci, even when encapsulated by calcification, has been abundantly demonstrated by Opie<sup>12</sup> and others, but the likelihood of exacerbation becomes progressively less with time and may be anticipated by prolonged and careful observation.

In order to study the results of this group in detail, a classification of the disease according to its clinical stages, modifying that of Mest,<sup>5</sup> has been found convenient:—

1. Glands enlarged, firm, mobile, and not matted.
2. Peri-adenitis, with matting but no gross softening.
3. Liquefaction with fluctuation; no reddening of the overlying skin.
4. Skin thin, reddened: ulceration inevitable.
5. Sinus.

In the present group 34 cases were at Stage I. when treatment was begun. The glands in 4 patients disappeared, in 19 became permanently small and shotty, and in 11 remained stationary in size; that is, a satisfactory result was obtained in all. Of 30 cases in Stage II. with associated peri-adenitis, 18 became "cured" and 12 went on to softening and abscess-formation.

The part played by iodine in this series is questionable, as improvement in some may have been spontaneous or due to some other factor, but the fact that not one of the early stage cases became worse while under treatment suggests that its value is not inconsiderable.

*Tuberculin.*—A standard preparation of old tuberculin was given to 42 cases by subcutaneous injection over periods of from two months to three years. Of these 4 were at Stage I. and 28 at Stage II., and in all a "cure" was obtained as defined above. The remaining 10 patients showed gross signs of softening prior to commencement of treatment, and all eventually broke down or were incised. This bears out the general opinion<sup>2</sup> that tuberculin is not likely to arrest a tuberculous process once extensive liquefaction has occurred. On the other hand, the results when treatment was begun in the stage of peri-adenitis without softening compare strikingly with those obtained by iodides (100 as against 60 per cent.), and in view of this virtual control series, argue strongly in favour of tuberculin.

*Surgical excision.*—Radical removal of tuberculous cervical glands had been attempted by a surgeon in 36 patients. In 25 of these there was a gross local recurrence of the disease; 1 patient developed phthisis and 1 a fatal generalised tuberculosis. Operation may therefore be said to have cured certainly not more than 25 per cent. Of the 35 surviving patients in this series, operation was followed in 13 by a persistent sinus. This is noted in relation to the argument often advanced in favour of surgical excision<sup>1 3 4 11 13</sup> that it anticipates the formation of a spontaneous fistula. In order to assess its ultimate cosmetic results, a control series was collected of 35 successive cases in which tuberculous cervical glands broke down spontaneously, owing to refusal or neglect of treatment in the earlier stages. The healed scars in both groups compare as follows:—

	Surgical excision.	Spontaneous ulceration.
Good .. .. .	8	8
Moderate .. .. .	15	12
Bad .. .. .	12	15

These figures suggest that the cosmetic results of surgical excision are not significantly better than

those of untreated cases which run a severe course under the least favourable conditions.

**Aspiration.**—Liquefaction occurred in 32 patients, and these were treated by aspiration, using the oblique approach of Calot.<sup>1</sup> Of these, 4 remained "closed" and subsequently subsided under iodide administration; in them a single aspiration sufficed and the cavity did not refill. In the remaining 28 patients a sinus ultimately formed along the needle-track. This was found to occur more frequently when rapid refilling took place, requiring repeated aspiration, and when the onset of softening had been acute, suggesting a superadded secondary infection. The injection of antiseptic and sclerosing solutions into the abscess cavity seemed rather to provoke sinus-formation than otherwise.

**Incision.**—Incision with drainage was performed in 70 cases. The cosmetic results were slightly inferior to those obtained by aspiration, but both compare very favourably with the results of surgical excision and spontaneous ulceration:—

Cases ..	Exoision.	Spontaneous ulceration.	Aspiration.	Incision.
		35	35	32
	Per cent.			
Good ..	23	23	37	37
Moderate ..	43	34	47	40
Bad ..	34	43	16	23

Of 16 patients giving "bad" scars, 15 were incised at Stage IV. with the skin thin and reddened, while of 26 giving "good" scars 14 were at Stage III. only. This suggests that to obtain the best cosmetic results the incision should be made through healthy skin, and should not be delayed until this has become involved in the tuberculous process; this is contrary to the practice of Miller<sup>11</sup> who allows softening to reach an advanced stage. Incision was followed in 12 patients by curettage of the abscess cavity. This did not appear to affect either the subsequent course of the disease or the ultimate cicatrix, and the percentage results were approximately the same as those obtained by simple incision. It is suggested that softening of a tuberculous gland and formation of "cold abscess" is not necessarily to be regarded as a catastrophe, but may on the contrary give a reasonably good result.

#### CONCLUSION

In the light of the foregoing observations of fact, I now adopt the following routine:—

1. When tuberculous cervical adenitis is in the earliest stage of simple hyperplasia, syrup. ferri iod. (B.P.) is given by mouth until the glands are permanently firm and contracted.

2. In the next stage of peri-adenitis, Beraneck's tuberculin is given by injection, according to the usual straightforward technique.

3. When there is enough softening to give physical signs of fluctuation, one of two surgical measures is adopted. If there is reason to believe that the process of liquefaction is slow, owing to its insidious onset and slow rate of increase, aspiration is performed: if, on the other hand, the abscess appears suddenly in a hitherto firm glandular mass, an early incision is made; this is also done in a patient, seen for the first time with the skin already involved in the

tuberculous process, as evinced by its being thinned and reddened. The old-fashioned Syme's "abscess knife" is preferred for this purpose. Free drainage is maintained until all discharge has ceased.

4. Whenever a sinus has formed, or has been produced by aspiration or incision, any residual glands receive conservative treatment according to their condition, on the lines indicated above. It has been observed that obstinate fistulae do well on tuberculin. Scrofuloderma is treated by ultra-violet irradiation.

5. Apparent cure is succeeded in all cases by observation for at least three years. Relapse and recurrence are not uncommon, but are equally amenable to the same methods of treatment. The average duration of iodide treatment is from 9–15 months, and of tuberculin from 3–6 months. An adequate supply of food and clothing is supplied through the care committee and home supervision is carried out by health visitors. Only in rare cases of grossly deficient home conditions is sanatorium treatment resorted to, or when the disease is accompanied by severe toxæmia or active tuberculosis in some other part of the body. Surgical excision is held to be unjustified by results and is never advised.

## Clinical and Laboratory Notes

### THE SPECTROGRAPHIC ANOMALIES OF GASTRIC JUICE IN PERNICIOUS ANÆMIA

BY LADISLAS KARZAG, M.D., Ph.D.

PRIVAT DOZENT OF INTERNAL MEDICINE AT THE UNIVERSITY OF BUDAPEST; CHIEF OF THE FIRST DEPARTMENT FOR INTERNAL DISEASES OF THE ST. ROCHUS HOSPITAL, BUDAPEST

Castle, Wilkinson and Klein, Cohn, Witts, Muelengracht, Gänsslen, Bence and others have drawn attention to the special rôle of the stomach in regenerating the blood in pernicious anæmia. This note records some observations I have made with Miss Hanák on the contents of the fasting stomach removed through a duodenal tube and examined by ultra-violet spectrographic tests. These contents prove to have a selective absorption spectrum, which is also shown by the ultrafiltrate of the juice. Further we found evidence that the substances producing this appearance in the spectrum are actively secreted in the stomach.

Absorption spectra of samples of the juice of the fasting stomach before an alcoholic test-meal and

FIG. 1.—Control group: (1) diabetes mellitus; (2) chronic nephritis; (3) subacute endocarditis; (4) cardiac cirrhosis; (5) hepatic cirrhosis; (6) renal tuberculosis; (7) diabetes mellitus; (8) neurasthenia; (9) chorea minor.

then at 10-minute intervals show that the meal at first lowers the extinction coefficient (see  $\epsilon$  in Figures) by dilution, but further fractions show a slight rise in the curves associated with the increased activity of the stomach.

After this, with J. Várady and F. Császár, I carried out tests on ultrafiltrates of the juice from fasting stomach in three groups of patients. The first consisted of those suffering from a variety of diseases (Fig. 1); the second, from hypo-acidity, including cancer of the stomach; and the third, from pernicious anæmia, and already treated with liver (Fig. 2). We found that the absorption curves of the patients suffering from pernicious anæmia were remarkably like those in the other groups. The group of gastric disturbances and the control group showed a scattering of extinction coefficient values with a low limit of 2.0 and only in exceptional cases did these groups show a coefficient lower than this. In contrast to these the ultrafiltrates of the gastric juice in pernicious anæmia showed groups with a lower level, and the extinction coefficient values were between 1 and 2.

I have since attempted to discover the substance which develops the selective action in the fasting stomach contents. It has been shown by chemical and also by spectrographic tests that these substances are not proteins, polipeptides, aromatic amino-acids, lactic acid, or bile-pigments. The results of my investigations strongly suggest that, from their physico-optical and physico-chemical properties, and also from their reactions to heat, acids, and alkalis, their solubility, and their power of absorption, these selective secretions of the stomach are due to a vitamin-B complex substance.

We hope that these researches may be valuable in helping us to discover the pathogenic factor of pernicious anæmia.

The investigations have been made with the financial assistance of the Count Stephen Széchenyi Society for furthering the knowledge of natural science in Budapest.

## TUBERCULOUS THROMBOPHLEBITIS OF THE LOWER EXTREMITY

BY EMIL ALTSCHÜLER

LATE SENIOR SURGEON OF THE JEWISH HOSPITAL,  
FRANKFORT-ON-MAINE

As far as I know, isolated tuberculous disease of veins, especially in the lower extremity, has not yet been described. I therefore consider it important to record two cases that I had occasion to observe while in Frankfort.

CASE 1.—A gardener aged 28. His father had died of pulmonary tuberculosis and his mother of asthma. He himself had suffered from several childhood illnesses and had been operated on for appendicitis.

In June, 1932, he had pain in the right leg. Painful cords appeared and he lay several weeks in the surgical wards of the University hospital. He left completely cured. When in October, 1932, the pains recurred he came under my care. Several thin cords 10–20 cm. long were found on the right leg and thigh; these were very

tender on the slightest pressure. He was otherwise healthy; X ray examination showed the lungs to be normal. The temperature was also normal and the Wassermann reaction was negative. I was struck by the absence of pyrexia and still more by the extraordinary multiple thin cords. They were about as thick as a knitting-needle and were very similar to those found in chronic inflammation of the lymphatic vessels. I suspected a specific disease of the veins and had an inflamed cord removed.

The pathological examination was made by Prof. Fischer-Wasels, director of the pathological institute of the University, and he reported that after examining numerous serial sections, several typical tubercles were found in the thickened and abundant intima of the veins.

Some time later the same symptoms recurred on the left lower leg. Being a public officer he was no longer allowed to be treated in a Jewish hospital and he therefore entered the surgical department of the University clinic. At my instance a diseased part of vein was removed for examination, and this also showed tuberculosis of the vein.

**CASE 2.**—A merchant aged 36. The family anamnesis was normal. He said he had had catarrh of the lung apex during his military service. A few years ago he was operated on for appendicitis. From July 20th, 1934, until August 2nd, 1934, he was in our hospital suffering from thrombophlebitis in the region of the saphenous vein. A thick painful cord stretched from the lower leg to the middle of the upper thigh, behind the knee. There was no raised temperature. The symptoms disappeared rapidly after treatment with leeches. On Oct. 10th he was again admitted because of the repeated thrombophlebitis in the same region. His organs were healthy and X ray examination showed the lungs to be normal. The surprising result of the examination in Case 1 led me to extract the diseased part of the saphenous vein and to send it to Prof. Fischer-Wasels. The microscopic examination showed a lumen completely filled with masses of thrombus, for the most part caseous. In the intima there were epithelioid cells and some quite typical tubercles.

In both cases I removed the inguinal glands and had them examined, but they were not diseased. The tissues in the neighbourhood of the diseased veins were also normal and the wounds healed by first intention.

Tuberculosis of veins has been described. Weigert published several cases with infection of the pulmonary vein, but there have been only a few with the thyroid, suprarenal, portal, azygos, or splenic veins affected. In all these, however, it was not a matter of a disease confined to the vein wall; the vein was infected by invasion from the surrounding tissues and there were always advanced tuberculous changes, with miliary infection of the viscera. In both our cases the organs are not demonstrably diseased. The tissue surrounding the vein was free from infection and only the intima was attacked. I cannot explain the ætiology; no portal of entry was discovered in the lower leg in spite of most exact interrogation of the patient.

I am no longer in a position, for want of material, to continue these examinations. I think that tuberculous disease of the veins of the extremities is not rare, and if this is so there is a wide field for research into its causes and its treatment.

Tel-Aviv, Palestine.

**TOXIC PURPURA HÆMORRHAGICA  
COMPLICATING SCARLET FEVER**

By J. E. MORRISH, L.M.S.S.A. Lond.

A GIRL, aged 7, was admitted to the Harrow Isolation Hospital suffering from scarlet fever.

On admission she had a brilliant erythema and a strawberry tongue; temperature 103.4° F.; pulse-rate 140. Scarlet fever antitoxin (10 c.cm.) was injected, and apart

from a trace of albumin in the urine on the second day she progressed without further complication until the eleventh day, when there was some pyrexia.

On the morning of the thirteenth day the night nurse discovered a small hæmatoma on the right hip which rapidly increased from the size of a penny to a circle of about 4 in. diameter. Both feet became bluish and painful in the sock area; the right eye showed conjunctival hæmorrhage and the temperature (see Chart) rose to 101° F.; pulse-rate 128, respiration 20. There were no adventitious heart sounds.

Calcium Sandoz (10 c.cm.) was injected intramuscularly and calcium lactate grs. 15 was given orally every four hours in a potassium citrate mixture. During the day the temperature dropped to 99° F. but the pulse-rate remained rapid. Other purpuric rashes appeared on the right knee and on the whole of the right thigh; both feet and ankles were swollen and dark purple in colour with

Temperature chart. Alb. sl. trace = albumin slight trace. S.F. antitox. = scarlet fever antitoxin. Calc. = Calcium Sandoz.

petechial spots showing through, causing the girl to cry with pain.

At 10.30 P.M. 10 c.cm. of the father's blood was withdrawn and injected into the child's buttock, and a draught of bromide and chloral was given to induce sleep and relieve pain. Next morning the child was obviously anæmic and there were hæmorrhages from the gums and nose. Both feet were now almost black and anæsthetic, but there seemed to be a ring of reaction around the edges of the smaller patches. Albumin had appeared in large quantities in the urine. The heart had a definite tic-tac rhythm; pulse-rate 160, temperature 100° F. She complained of abdominal pain, probably due to intestinal hæmorrhages; palpation was difficult, however, owing to rigidity, but no enlargement of the spleen could be felt.

Another 10 c.cm. of calcium sandoz was given intramuscularly. Dr. Robert Hutchison advised the further injection of serum into the buttock, as the veins were so collapsed that it was impossible to get into them. An enema was given late that night and grs. 10 of chloral was left in the rectum, following a bout of violent abdominal pain and sickness. The temperature dropped to 99.8° F. and she died at 3.45 A.M. From the onset of the purpura to death occupied about 48 hours.

I think I am right in saying that this case is unusual. Most authorities, with a few exceptions, describe these fatal cases attended with hæmorrhage as occurring in the first few days of scarlet fever, and not as late as the fourteenth day. The complete failure of treatment, even after two injections of serum, is noteworthy. Could it be that the serum activated the symptoms rather than controlled them?

## MEDICAL SOCIETIES

MEDICAL OFFICERS OF SCHOOLS  
ASSOCIATION

At the annual meeting of this association, held at the rooms of the Medical Society of London on April 17th, with Dr. J. LAMBERT (Wellington College), the president, in the chair, a discussion took place on

**Administrative Difficulties in the Construction of a School Sanatorium**

Dr. R. E. SMITH (Rugby School) said in building a new sanatorium the governing body had to consider not only the site and the cost, but also problems which arose in consultation with the selected architect. The latter should have had a wide experience of hospital construction, and this of itself was some guarantee that money would not be wasted. The Royal Institute of British Architects, in regard to competitive buildings, discouraged the award of the work automatically to the one whose tender was lowest, and a Fellow of that body would listen to constructive suggestions. Rugby School had a population of 600, and the number of days spent by boys in the sanatorium in three successive years was as follows:—

	Spring term.	Summer term.	Winter term.
1933 .. ..	2762 .....	897 .....	858
1934 .. ..	2340 .....	925 .....	1421
1935 .. ..	1486 .....	1508 .....	884

The average population in the sanatorium was 30, 12, and 12 respectively in the three terms.

The position of the site depended to some extent on whether all cases were to be dealt with in one building. In some schools infectious cases were housed in a separate building, but the modern tendency was to have all departments under one roof, when medical and nursing attention was more efficient. Dr. Smith had never seen an infection transmitted from an in-patient to an out-patient. A sanatorium in a central situation was visited more readily by boys than one at a distance, and also more convenient for housemasters. The number of beds in a sanatorium depended on many factors, discussed by Sir Weldon Dalrymple-Champneys in 1928. Less than the proportion formerly recommended (10 to 20 beds for each hundred boys) was now being advised by medical experts. Preparatory schools, where the number rendered immune by a previous attack of acute infectious diseases was relatively low, would need a higher proportion of beds than schools for older boys. Measles could now be controlled by convalescent serum therapy; at boarding schools this disease showed a biennial periodicity if attempts were not made to prevent contacts from returning. Diphtheria was the one disease against which prophylaxis was almost perfect; it had a low incidence in residential schools. Scarlet fever was troublesome, as patients had to be subjected to a long quarantine. Four weeks had been shown to be a better quarantine period than six weeks. The best policy, however, was active immunisation. Dr. Smith's view was that 10 beds for each 100 boys sufficed for a school sanatorium, provided each house in the school had in addition one sick room for every 30 boys. He was strongly in favour of a number of single-bed wards; two-bed wards he regarded as useless. Moreover, cases of measles were far better

nursed in single rooms than in large wards, though they should be transferred during convalescence. Only in this way could droplet infection be reduced to a minimum, and such serious complications as pneumonia, otitis media, and mastoiditis be avoided. The cubic capacity of the single-bed wards need not exceed 1500 ft., especially in the presence of adequate cross-ventilation. Possibly school sanatoria erected in the future would be equipped with air-conditioning plants. As to windows, his own preference was the double-sash window with metal chain sash cords. A fanlight above the door facilitated cross-ventilation. The public at large still needed convincing of the great value of the open window in pyrexial illnesses so long as the patient was kept warm.

The provision of facilities for operating in public schools was useful and might assist schools to secure the right type of men as health officers, though admittedly some conditions were best dealt with in a general hospital. For sterilising purposes Dr. Smith preferred electricity. The provision of sufficient recreation rooms was most important, as the management of boys during convalescence taxed the medical resources of the doctor as much as did the acute phase of their illness. Large wards should have coal fires in them and a varied library. Every effort should be made to reduce noise to a minimum.

Mr. LIONEL PEARSON, F.R.I.B.A., showed pictures of the new Masonic sanatorium for girls at Rickmansworth, designed by Mr. Denman, which was held to be one of the best sanatoriums in the country. Many of the points made by Dr. Smith were insisted upon in the Ministry of Health memorandum, but the school sanatorium presented rather a different problem when infectious disease and cases of ordinary illness were treated in the same building. Mr. Pearson had reason to believe that there was a strong desire among medical men for the provision of cubicles for cases of infectious diseases, one reason for this being that the length of stay of the patient was thereby shortened. It had been said on good authority that there were only two ways of dealing with children in hospitals: to segregate them into cubicles, or to insist on their wearing masks to prevent the spread of infection. He shared Dr. Smith's disapproval of two-bedded wards, though something could be said for them from the social standpoint of avoiding tedium. His own view was that the difficulty was best overcome by having cubicles with glass divisions, as supervision was very important. As to cubic capacity, it was no longer considered essential to provide 1500 cubic feet space for each acute case. The important point was floor space; for a single patient in a cubicle the floor space should be 12 by 10 ft., and in open wards 10 by 10 ft. per patient. Similarly a height of 15 ft. was no longer demanded, as nothing over 10 ft. from the floor apparently made any difference. A distance of at least 8 ft. between the centres of adjacent beds was important in order that infection should not be conveyed by coughing. A schoolmaster told him he had materially reduced the incidence of illness by forbidding coughing in class-rooms; boys with the urge to cough had to leave the class. If screens were objected to, the barrier system of preventing spread of infection could be adopted. As to fittings, sash windows tended to rattle in a wind and disturb sleep; casement windows were much more popular with matrons and nurses. He asked whether cross-ventilation was essential if plenty of air was entering the ward. In

side-lighted rooms fanlights over the doors would provide sufficient air currents. Air-conditioning he did not particularly favour; it must include filtering and washing the air, and unless the school was situated in a slum area there would be ample direct contact with the outside air. For heating he preferred radiators under the windows, but, despite the trouble of stoking and cleaning, open fires were good and cheering in a ward.

Dr. G. E. FRIEND (Christ's Hospital) said that occasionally he had to cope with a considerable number of sick boys, and in the presence of mixed epidemics it was necessary to convert one of the school houses into a hospital. Hopper windows were put in and proved satisfactory; the time of convalescence was reduced by 25 per cent. in the improvised building thus fitted, compared with the infirmary building. He thought the variations of hospital design in different countries might be largely dictated by the average amount of sunshine.

Dr. W. G. WILLOUGHBY (Eastbourne) said that in the infectious diseases hospital with separate blocks there was no difficulty about having the windows open in summer; the difficulty arose in winter, especially when cross-ventilation existed. In blocks built in 1902 open fires were provided; air coming in was heated by the fire and distributed throughout the ward without draughts. He referred to the grave illness and mortality statistics in inhabitants of back-to-back houses, due mainly to the lack of through ventilation. It was important to employ an architect with special experience.

Dr. L. R. LEMPRIERE (Haileybury) endorsed the praise given to the design of the Rickmansworth Hospital. He was opposed to the provision of an operating theatre in school sanatoria. Most public schools were conveniently near a well-equipped and well-staffed provincial hospital, and it was very much better, in his opinion, that operation cases should be dealt with there. He did not think that any school medical officer could be expected to be operating surgeon to the school, since his hand could easily lose its cunning when few operations were required. He was against coal fires in wards, quite apart from the dirt and the trouble of keeping them going. They failed to maintain an equable temperature, and schools catered not only for infectious cases, but for acute cases and convalescents. As soon as he was fit, the boy should be put down in the recreation room, a provision which most school architects ignored. An objection to large windows was that the blinding sun on a hot day could not be properly shut out. The amount of sunlight reaching patients in the summer could be overdone; it might interfere with sleep. The perfect flooring for a sanatorium had not yet been achieved, but the nearest approach, he thought, was cork. He agreed with the objection to two-bedded wards; a public school sick house could possibly be a starting-point of immorality. A vital necessity was the provision of a detention room. Sick boys who might be incubating an infectious disease must not be mixed with convalescents. He would like to see every sanatorium equipped with a dark room, for transillumination aids to diagnosis. The provision of a parents' room was desirable.

Mr. DENMAN, F.R.I.B.A., spoke of the modifications made from reasons of economy of his original design for the Rickmansworth sanatorium.

Mr. H. M. FAIRWEATHER, F.R.I.B.A., did not think there would be agreement as to the best kind of window; he would be sorry to feel that metal windows

only were to be used for hospitals and sanatoria. The chief inquiry made by parents concerning a school was about the provision made for caring for them when sick.

The PRESIDENT expressed his leaning towards single cubicles and separate rooms for school sanatoria. At the beginning of a school term a number of boys had a temperature and the uncertainty as to what would develop made a particular need for single cubicles. School sanatoria should have sufficient single cubicles, and sufficient three- or four-bedded rooms.

## NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

A MEETING of this society was held in Liverpool on March 20th, with Dr. RUTH NICHOLSON, the president, in the chair. Two cases of

### Simmonds's Disease

were reported by Mr. J. ST. GEORGE WILSON. He said that this syndrome, which is commoner in women, was first described in 1914, and is typified by progressive loss of weight and senile changes—such as loss of hair, an aged appearance, inhibition of genital function, and amenorrhœa. Lassitude and weakness are conspicuous. The basal metabolism is much lowered and the pulse is slow. There is anæmia and there may be hypoglycæmia. Radiologically there may be enlargement of the sella turcica if the lesion is a neoplastic destruction of the pituitary.

The first patient, aged 29, had complained of loss of weight, following a normal confinement; her weight, previously 11 st. 7 lb., had been reduced to 5 st. 11 lb. within four years. There had been daily vomiting, dizziness, and loss of power in the left hand. She had, however, no loss of hair and did not look prematurely aged. She had complained of amenorrhœa for the last 12 months, her periods having previously been irregular. On examination she was found to be poorly nourished. The blood pressure was 114/72 mm. Hg and the pulse-rate 44. The cervix was multiparous and the body of the uterus small. X ray photographs of the skull revealed no abnormality. The blood-sugar was 81 mg. per 100 c.cm., non-protein nitrogen 33 mg., Wassermann negative. She was treated with injections of insulin and Pregnyl and with extra salt in the diet.

The second patient, aged 37, also dated her symptoms to a confinement. She had complained of loss of weight for 21 months, nausea for 20 months, and weakness for 6 months. She was stated to be looking much older than previously, and had had amenorrhœa for 28 months. On examination her weight was found to be 4 st. 10 lb. She had hair on the face, pigmentation of the abdomen, a blood pressure of 98 mm. Hg, and a pulse-rate of 42. The urine was normal and a radiogram of the skull revealed no abnormality. She had complained of amenorrhœa constantly for the last 12 months, having previously had scanty periods at intervals of 5-6 months. On pelvic examination the uterus was found to be senile. She was treated by injections of Antuitrin S and Œstroform and was given olive oil. Eight months later she had gained 3 st. in weight.

In the discussion, Mr. S. B. HERD commented on the fact that in each patient the condition had closely followed pregnancy. He wondered if in the past these cases had merely been considered as instances of superinvolution.—Mr. T. N. A. JEFFCOATE said he considered superinvolution of the uterus always to be due to pituitary disease. He also questioned whether there was not in Simmonds's disease an element of suprarenal dysfunction as well.—Dr. E. A.

GERRARD referred to the relationship between super-involution and prolonged suckling. He did not agree that it necessarily meant a diseased pituitary.—Mr. F. E. STABLER asked if an Aschheim-Zondek test had been performed: he had seen a case of the condition in which it was slightly positive.—Mr. ST. GEORGE WILSON said that such a test had not been done, but he would certainly have one carried out.

Mr. C. MCINTOSH MARSHALL described two cases of  
**Uterine Rupture Associated with Placenta  
Prævia**

In the first the rupture was spontaneous and in the second it was traumatic.

The first patient was a 4-para aged 29. She was admitted to hospital, believing herself in labour, but the pains passed off. The pregnancy, according to the usual calculations, was at the forty-second week, the presentation was right occipito-posterior and the head high above the brim. Vaginal examination a week later revealed a lateral placenta prævia, the os admitting one finger. After a further week, pains began spontaneously and after nine hours in labour some blood and clots were suddenly passed from the vagina. Vaginal examination showed that the cervix, though not too well taken up, admitted two fingers and that the membranes were ruptured. The os was partially covered by the placenta which was on the posterior wall of the lower segment. The child's head was macerated and there was much overlapping of the parietal bones, the anterior over the posterior. Willett's forceps was applied to the scalp and a weight of 1 lb. attached. No further bleeding occurred. Four hours later the child, which weighed 5 lb. 11 oz., was delivered. It was macerated and had an offensive odour. No bleeding followed the birth of the child, but an hour later the patient's condition had deteriorated, she was pale, and her pulse was rapid and soft. The placenta had not been delivered. Morphia and a saline were given and the foot of the bed was raised. During the next few hours her condition improved a little and four hours after delivery it was decided to remove the placenta. As soon as anæsthesia had been induced a blood transfusion was commenced, and on passing the hand into the uterus a laceration was discovered in the lower segment. The abdomen was rapidly prepared and a laparotomy carried out on the labour bed. A large amount of free blood was found in the peritoneal cavity, also the placenta. There was a vertical tear 3-4 inches in length in the posterior wall of the lower segment and cervix. Subtotal hysterectomy was performed and a drainage-tube inserted. Convalescence was stormy, but eventually the patient made an excellent recovery.

Mr. Marshall referred to a case reported by H. D. de Sa in which spontaneous rupture of the uterus had also occurred through the placental site.

The second case was a primipara, aged 22, who was six days over her expected date, the head being still above the brim. A stomach-tube induction was carried out by an experienced house surgeon. A general anæsthetic was not employed, but the tube was passed under direct vision, a speculum being used and the anterior lip of the cervix grasped with a sponge forceps. When about 2 inches of the tube had been inserted some resistance was met with, but was easily overcome and the rest of the tube was inserted without difficulty. Pains commenced 5 hours later, and after a further 10 hours the cervix was almost fully dilated, the head however being still above the brim. The stomach-tube had not been extruded. A catheter being passed, the urine was found to be heavily stained with blood: Mr. Marshall was then called to see the case and on cystoscopy the stomach-tube, which had been palpated through the anterior vaginal wall, was clearly seen in the bladder. Delivery of a living child was effected by version and extraction, and the placenta, which was inserted low on the anterior uterine wall, was removed manually. It was noted that its lower edge was about 1 inch from the cervical lip. A median suprapubic incision was made,

and the uterovesical pouch of peritoneum was inspected. No injury was seen. The peritoneum was then closed and suprapubic cystotomy was carried out and the tube removed. The bladder was drained. Cystoscopic examination a month later revealed a small slightly raised puckered area lying behind the base of the bladder. This had a similar appearance to the cystotomy scar in the fundus.

Mr. ST. GEORGE WILSON expressed a doubt whether, in the second case, the stomach-tube had passed through the placental site. He was inclined to think that it had been forced through the wall of the cervix.—Mr. STABLER held that the first case could hardly be considered as one of spontaneous rupture, since Willett's forceps had been applied. Regarding the second case, he felt that a tube should never be passed without general anæsthesia. Apart from the difficulty which might be experienced, it was impossible otherwise to ensure an adequate aseptic technique.—Dr. GERRARD supported the latter observation and spoke of the morbidity associated with bougie induction.—Mr. C. H. WALSH questioned whether true spontaneous rupture of the uterus ever occurred. It was interesting to note that all cases reported had been in multiparæ, and the suggestion was that trauma at a previous confinement was really the ætiological factor.

In reply, Mr. MARSHALL said that he felt sure that the tube had not perforated the cervix but had been deflected by the edge of the placenta and had passed through the placental site. He also referred to blood transfusion as a most valuable and life-saving measure in cases of placenta prævia.

**Renal Calculi in Pregnancy**

Mr. WALSH said it had been noted that kidney stones were rare in pregnancy, this being accounted for by the fact that renal lithiasis occurs as a rule in women between the ages of 30 and 50, and most pregnancies before 35. The condition presented many interesting features regarding diagnosis, the value of biochemical tests as a guide to treatment and prognosis, and the particular line of treatment to be decided upon. A further point of interest was the ureteric dilatation normal in pregnancy.

He had seen three cases of renal lithiasis in pregnancy during the latter half of 1935.

The first patient, a 3-gravida aged 36, was seen at the fourteenth week. She had complained of pain in the left loin for two years, worse recently. The urine contained blood and *Bacillus coli*, but no casts were present. The blood pressure was 120/75 and the blood non-protein nitrogen 33 mg. per 100 c.cm. Radiography revealed two stones in the left kidney. Nephrolithotomy was decided upon in consultation with Mr. J. C. Ross, who removed the calculi. Convalescence was uneventful and the patient, whose urine became clear ten weeks after the operation and remained so, was delivered at term of a child weighing 7 lb. 12 oz.

The second patient, a 3-gravida aged 30, was first seen at the twentieth week of pregnancy. She then had albuminuria but the blood pressure was 120/75 mm. Hg. She was regarded as a mild case of toxic albuminuria and treated as such, but the albumin increased in amount, and she was admitted for investigation. The output of urine was up to 67 oz. per day and a trace of blood and pus was found, also *B. coli* in moderate amount. The blood non-protein nitrogen was 45 mg. per 100 c.cm., the urea concentration 1.85 per cent. at the third hour. She improved with rest and dieting, and was discharged two weeks later, the urine containing a trace of albumin only. She was readmitted at the thirty-sixth week with severe œdema and albuminuria, and, having slight hydramnios, she was radiographed. A large branched calculus was apparent in the right kidney. Mainly on account of the

hydramnios and oedema it was decided to induce labour at the thirty-eighth week. The labour and puerperium were normal. Three months later, after further renal investigation had revealed a functionless right kidney, nephrectomy was performed.

The third patient, a primigravida aged 20, was admitted at the twentieth week. She was acutely ill and had symptoms simulating acute appendicitis, though the urine contained some albumin and pus. An incision was made in the right iliac fossa, and an extraperitoneal abscess was found. Because the condition might have been a retro-cæcal appendix, it was felt necessary to open the peritoneal cavity. This was done after careful packing off but the appendix was found to be normal. The extraperitoneal tissues were drained and the wound partially closed. The wound drained freely and the acute symptoms settled at once. The pus contained *B. coli* and non-hæmolytic streptococci. Radiography ten days later revealed a large calculus in the right kidney. Blood non-protein nitrogen was 32 mg. per 100 c.cm., the urea concentration 1.95 per cent. at the end of three hours. The wound had completely healed in six weeks, and though the surgeon was anxious for the pregnancy to be terminated so that the kidney condition could be treated, Mr. Walsh decided not to interfere. She was kept under observation week by week, during which time her general health remained extremely good, went into labour at the thirty-eighth week, and was delivered by natural forces of a child weighing 5 lb. 4 oz. The puerperium was uneventful and she was discharged on the twelfth day.

Mr. Walsh remarked that only in the first case was it possible to suspect a renal calculus on the history, and in view of this, it seemed likely that renal stones were not infrequently missed. The second patient had been operated upon for chronic appendicitis and had been treated for toxic albuminuria before radiography on account of hydramnios revealed the true state of affairs. Regarding the investigations which are usually undertaken, he inquired if there was any biochemical test which would serve as a guide to prognosis and treatment in renal pathological conditions during pregnancy. After an investigation of the blood pressure, blood-urea, and urea concentration of a number of cases of toxic albuminuria, and a correlation with clinical results, he was of the opinion that only the blood-pressure reading was a reliable guide. The urea concentration and blood-urea were much too erratic to give any guide to prognosis. This applied particularly to toxic albuminuria, but it was not out of place in discussing renal calculi.

Ureteric dilatation during pregnancy was evident on the sound side in each of the three cases, and was demonstrated by injection of Uroselectan and radiograms. This was a normal state of affairs during pregnancy, and had originally been attributed to pressure on the ureters at the pelvic brim by the pregnant uterus. There seemed little doubt in view of recent work that this theory was quite wrong and that the true explanation lay in an altered endocrine function present in pregnancy and affecting all involuntary muscle, acting either directly or in conjunction with the sympathetic nervous system.

On the question of treatment of diseased organs complicating pregnancy, Mr. Walsh thought there was a widespread tendency towards terminating the pregnancy as a preliminary to surgical treatment. He considered this attitude to be entirely wrong and felt that, speaking generally, even severe surgical conditions could be treated with little risk of interrupting the pregnancy. Applying these principles to the three cases under review, he considered that the first case was correctly treated by nephrolithotomy at the fourteenth week. In the second the renal lithiasis was not diagnosed until the thirty-sixth week,

and there was thus little to be gained and much to lose by operation at that time; in the circumstances induction of labour at the thirty-eighth week appeared to be rational. Looking back on the third case, he felt that nephrectomy at the twenty-fourth week was the method of choice, despite the fact that, as things turned out, conservative treatment resulted in a live birth, leaving a diseased infected kidney to be removed later.

He summarised his conclusions as follows: (1) the diagnosis of kidney stone is difficult and liable to be mistaken for conditions peculiar to pregnancy; (2) in reading radiograms during pregnancy after intravenous injection of uroselectan, it should be remembered that there is normally a state of ureteric dilatation; (3) urinary and blood biochemical tests are of no help in prognosis or as a guide to treatment; and (4) the guiding principle to treatment should be to remove the stones or kidney and ignore the pregnancy.

Mr. J. W. BURNS agreed that the biochemical tests were of no value, and was pleased to hear that Mr. Walsh had the courage of his convictions. He felt that the blood pressure was more useful as a guide to treatment in albuminuria.

Mr. P. MALPAS could not agree with the previous speakers, and thought that the non-protein nitrogen index had a certain value in eclampsia, especially if taken together with other findings and the clinical condition of the patient. If there was gross liver damage, the index might not be grossly increased, although the patient was gravely ill. He referred to six patients whom he had recently come across suffering from renal calculi.

Mr. A. A. GEMMELL supported Mr. Malpas and attached some value to renal efficiency tests during pregnancy. These were useful if fitted in with the clinical condition. He had found the blood-urea and the urea-concentration tests improved in cases where the foetus died in utero.

Mr. C. J. K. HAMILTON referred to a patient of his own with renal calculi who gave an 8-year history of hæmaturia. There was a large branched calculus in the left kidney. Pregnancy was allowed to continue until the thirty-eighth week when induction was carried out for disproportion. The hæmaturia disappeared after delivery.

Mr. MARSHALL thought that the liver damage vitiated the blood non-protein nitrogen index and referred to a case in which he decapsulated the kidneys because of the clinical condition of the patient, although the index was under 40 mg. per 100 c.cm.

Mr. JEFFCOATE gave a demonstration of a suction curette which could be used as a diagnostic aid, particularly in cases of endocrine dysfunction; an important feature was that an anaesthetic was not required.—Mr. C. HENDERSON showed a specimen of a pregnant uterus and vesical calculi with bilateral pyonephrosis.

OPHTHALMIA NEONATORUM: TECHNIQUE OF IRRIGATION.—Mr. J. D. Magor Cardell, whose opening paper in a discussion at the Ophthalmological Society of the United Kingdom was reported on p. 842 of our issue of April 11th, writes to correct the impression given that the cornea should deliberately be massaged during irrigation. The actual words he used are these: "While the irrigating stream is still flowing, one finger of each nurse is gently drawing the lids apart without pressure on the globe, and at the same time travelling to and fro across the lid. This delicate massage avoids the cornea and coaxes pus out of the fornices."

## REVIEWS AND NOTICES OF BOOKS

**Recent Advances in Dermatology**

By W. NOEL GOLDSMITH, M.D. Camb., M.R.C.P. Lond., Physician to St. John's Hospital for Diseases of the Skin; Assistant Physician to the Skin Department, University College Hospital. London: J. and A. Churchill Ltd. 1936. Pp. 522. 18s.

THIS book is not merely a catalogue of advances in post-war dermatology. It is a notable attempt to tell a connected story, and although largely academic in substance and style, contains much that is practical and explanatory of the trend of thought in a subject that has become complex in the field of medicine. One must admire Dr. Goldsmith's acquaintance with the literature, and the discrimination that marks his selections from the immense amount of published matter he has obviously had to study. Dermatology is no longer a closed circuit. Its practitioners to-day must have at least a nodding acquaintance with the problems of immunology, biochemistry, psychology, and the interactions of the endocrine and sympathetic systems. These are all considered in this work. The author's recommendation to "plough bravely through the chapters in their proper order" will not, we think, be generally followed. For our part we would prefer to take the work in small doses, for it is concentrated stuff. It is satisfactory to note that Lewis's classical studies on the so-called "triple response" have at last achieved a place in dermatology. The chapter on allergy is the least clear, even though a brief glossary of definitions is supplied. To many of us it may appear that the problem of eczema, considered in the light of the allergic response, has not yet been finally solved, and it seems doubtful whether the issue is really as clouded as current theories would suggest.

In other sections of this work Dr. Goldsmith is more practical. That dealing with lupus erythematosus provides sound reasoning and a most useful summary of therapeutic experiences. It is impossible here to comment on more than a few sections of a work which, if rumour is correct, has occupied the author's leisure hours for a period of three years. It seems likely that serious students of dermatology in every country will find this book indispensable.

**A Glasgow Manual of Obstetrics**

Second edition. By SAMUEL J. CAMERON, M.B., F.R.F.P.S., F.C.O.G., Regius Professor of Midwifery, University of Glasgow; JOHN HEWITT, M.B., Ch.B., F.C.O.G., Hon. Lecturer in Clinical Surgery at the University; ROBERT A. LENNIE, M.D., F.R.F.P.S., F.C.O.G., Obstetric Surgeon to the Royal Maternity and Women's Hospital, Glasgow; and ELLEN D. MORTON, M.B., Ch.B., M.C.O.G., Hull Tutor in Obstetrics at the University. London: Edward Arnold and Co. 1936. Pp. 611. 21s.

GLASGOW and its surroundings appear to differ from any other part of the British Isles in the incidence and degree of cases of contraction of the pelvis. One result of this peculiarity is that this book, which provides an account of the teaching of the Glasgow school of obstetrics, devotes far more space to descriptions of varieties of bony deformities and to the management of such cases when pregnancy occurs than do corresponding productions emanating from other centres. The investigation, diagnosis, and

treatment of minor degrees of disproportion is described clearly and in great detail. Other chapters which deserve special mention are those on the treatment of antepartum hæmorrhage, on shock, and on puerperal infection. It is interesting to note that in Glasgow the condition of hyperemesis gravidarum is regarded primarily as toxic in origin, whereas in many English schools this variety is believed to be extremely rare. Narcosis in labour is obtained by the use of morphia, scopolamine, and paraldehyde rather than by the barbiturates. We would suggest that half a page is hardly sufficient space to allot to delay in the first stage, one of the most common difficulties experienced in labour. Under the same heading, and presumably considered as a cause, is placed carcinoma of the cervix uteri; nearly three pages are devoted to the treatment of this condition, which must be a rare complication of labour. Cæsarean section (the classical operation) is the method of choice in the treatment of placenta prævia, Willett's forceps being given a mere mention.

Apart from the differences to which we have drawn attention and a few others of minor importance, most English obstetricians would agree with the teaching here set out. The book is easy to read, and the illustrations, especially the photomicrographs, are extremely clear.

**Bacterial Endocarditis**

By C. BRUCE PERRY, M.D. Brist., M.R.C.P. Lond., Professor of Medicine in the University of Bristol. Bristol: John Wright and Sons Ltd.; London: Simpkin Marshall Ltd. 1936. Pp. 137. 10s. 6d.

ALTHOUGH there are maladies more consistently fatal than bacterial endocarditis, this disease is generally regarded as one of the most hopeless which affect mankind. So pessimistic is the outlook that interest in this condition centres on its relation to rheumatic endocarditis, and in bacteriological and diagnostic problems, rather than on therapeutics. Prof. Bruce Perry, who has conducted investigations on bacterial endocarditis under the R. L. St. John Harmsworth Memorial Research Fund, has now issued a monograph incorporating this work. The opening chapters are concerned with an exceptionally interesting historical survey in which the evolution of modern knowledge of these diseases is traced from the earliest records over 200 years ago to the present time. In the following section, on bacteriology, Dr. Perry has collected together 1000 cases from various sources in the literature. These show the following ætiological distribution: streptococci (all varieties) 68.1 per cent., staphylococci 10.3 per cent., pneumococci 11.2 per cent., gonococci 4.6 per cent., *B. influenza* 2.6 per cent., meningococci and *B. coli* each less than 1 per cent. The relation between rheumatic carditis and bacterial endocarditis is discussed in terms of morbid anatomy and ætiology; Dr. Perry finds that the weight of evidence is in favour of the hypothesis of Von Glahn and Pappenheimer that "the infection of cardiac valves with non-hæmolytic streptococci in rheumatic patients is due to the implantation of bacteria on unhealed rheumatic vegetations." It appears unlikely that the two diseases represent responses of different intensity to the same infective agent, since organisms other than non-hæmolytic streptococci may be implanted on active rheumatic vegetations, and since it is only in some cases of bacterial endocarditis

that evidences of active "rheumatic" changes in the valve are also found. Sections on clinical features, diagnosis, and hæmatology are, like the rest of the work, based upon an extensive bibliography and supplemented by personal observations and studies.

Dr. Perry's monograph brings up to date and endows with new interest a group of morbid conditions that have of late years received scant attention. It must not be forgotten that close scrutiny of clinical features may in the end yield the clue to successful therapy.

### Ideal Birth

By TH. VAN DE VELDE, M.D. London: William Heinemann Ltd. 1936. Pp. 269. 10s. 6d.

READERS of Dr. Van de Velde's books are familiar with his literary habits. He likes to interpolate aphorisms, and even intermezzos of aphorisms, throughout his text, to quote turgid German poetry, to exalt the subjects about which he writes to mystical levels. These habits have apparently been responsible for the large sale of his books, of which the best known is "Ideal Marriage" (1928). In the five books issued since then these characteristics have been becoming more conspicuous. This one has all the faults of its predecessors—long windedness, sentimentality, inaccuracy—with a new one added; it is badly translated. The book, we are told, is written for future fathers and mothers, for midwives and nurses, and the dust cover says that it can confidently be recommended to doctors. We do not endorse this recommendation.

### The Tuberculin Handbook

By HALLIDAY SUTHERLAND, M.D. London: Humphrey Milford, Oxford University Press. 1936. Pp. 96. 7s. 6d.

THE author of this handbook believes that, apart from the discovery of the tubercle bacillus, Koch's greatest gift to mankind was the introduction of tuberculin for the diagnosis and treatment of tuberculosis. He sets out in non-technical language the most important varieties of tuberculin, exotoxic and endotoxic, the standardisation of old tuberculin, and the recent work of American biochemists on tuberculin split products. Hypersensitiveness to tuberculin in tuberculous subjects is regarded as a specific phenomenon. In a chapter on the use of tuberculin the author describes the early symptoms, physical signs, and radiological appearances of pulmonary tuberculosis; in a subsequent chapter the percutaneous test of Moro, the cutaneous test of Pirquet, and the intracutaneous test of Mantoux. In practice he begins with a series of intracutaneous tests and when a reaction occurs he uses the subcutaneous test to determine whether the infection is latent or active. He does not aim at focal reactions—indeed he seeks to avoid them—but he has seen no harm follow them. A positive diagnosis of active tuberculosis having been thus established a course of tuberculin treatment is begun without delay. But Dr. Sutherland does not think that the diagnosis of pulmonary tuberculosis can always be made with certainty either by tuberculin testing or by radiograms alone; regard must be taken to history, symptoms, and physical signs. A tuberculin test may, however, help to correct interpretation of radiological evidence and vice versa. Of the essential value of tuberculin treatment the author has no doubt, whether for pulmonary tuberculosis, tuber-

culous adenitis prior to caseation, tabes mesenterica, or tuberculosis of eye and kidney. "Let it be noted," he writes, "that tuberculin gives the best results, and at a fraction of the cost, in those very cases which most sanatoriums are desirous of admitting. If tuberculin treatment can do as much or more than sanatorium treatment, then obviously it would be better that the febrile cases, needing rest and then graduated activity, should be sent to sanatoriums until they have become suitable cases for tuberculin treatment at home. In that way existing organizations could cope with the disease."

### Emergency Surgery

Second edition. By HAMILTON BAILEY, F.R.C.S., Surgeon, Royal Northern Hospital, London; Surgeon and Urologist, Essex County Council. Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall Ltd. 1936. Pp. 842. 50s.

THIS popular text-book of surgery, which has been thoroughly revised and in part rewritten, now appears very conveniently in one volume instead of in two. Here emergency treatment in every branch of surgery is described in simple and sometimes even colloquial language. It is evident that the author has had an extensive and varied experience in this kind of work. His recommendations are essentially practical and his judgment is sound. We like particularly his advice to open, if possible, a subphrenic abscess in two stages when it must be done transpleurally; and, should a pelvic abscess after appendicectomy be discovered by laparotomy, to close the wound and to open the abscess by the rectal route. The method of opening the abscess by the forcible use of a blunt instrument (a procedure also advocated for evacuating a collection of blood in Douglas's pouch) does not however appeal to us. It is doubtful also whether the ligation of the ileocolic vein in appendicitis is so often necessary as the author seems to have found it in his practice. Nor is it generally accepted that intravenous mercurochrome is effective in appendicitis and osteomyelitis. The lower approach to a strangulated femoral hernia is held by Mr. Hamilton Bailey to be so objectionable that no description of it is included. There is other debatable matter, but for the most part surgeons in the earlier stages of their emergency experiences will find the book an excellent guide.

### Medical Guide for India and Index of Treatment

Fourth edition. By Lieut.-Colonel E. J. O'MEARA, I.M.S. (Retd.), O.B.E., F.R.C.S. Eng., D.P.H. Cantab., late Civil Surgeon and Principal of the Medical School, Agra. London and Calcutta: Butterworth and Co., Ltd. 1935. Pp. 1234. 25s.

THE author of this book set himself 16 years ago to provide practitioners in India with a compact medical guide to help them in dealing with their very varied daily work. The book has now reached a fourth edition in which all the more important sections have been recast and more articles by specialists have been included. The fact that some of these—notably those by Lord Horder and Lord Moynihan, Dr. E. P. Cumberbatch, and Prof. J. A. Ryle—are reprinted by permission from issues of medical journals published between 1930 and 1933 would diminish their value for workers who have easy access to current literature, but is probably of less moment to Indian practitioners. The work

consists of twelve sections of which the largest (312 pages) is an Index of Treatment, brought up to date and remodelled in this edition so as to provide more convenient facilities for reference. Therapeutic measures are considered in the next section; the subjects are discussed for the most part under such general headings as exercise, radium therapy, organotherapy, so that it is surprising to find a chapter devoted to such a subdivision of drug therapy as "organic arsenic compounds." Food and the principles of dietetics provide the material for the third section. Useful chapters here are those on articles of Indian diet and methods of their preparation, and on scales of diet for European and for Indian patients in general and in mental hospitals. The fourth section on surgery takes up 100 pages, with chapters on acute abdominal disease, general anæsthesia, anti-septics, dental surgery, ear and eye diseases, errors of refraction, colour-blindness, instruments, dressings

and accessories, manipulative surgery, preparation for operations, after-treatment and complications, and throat and nose diseases; whereas medicine gets only 50 pages, the three chapters being entitled Medical Notes, Recent Advances in Medicine, Examination for Life Insurance. Section VI. is devoted to obstetrics and gynecology, section VII. to surgical, medical, and obstetrical nursing, section VIII. to preventive medicine and sanitation, and section IX. to medico-legal questions and lunacy. Diagnostic methods and pharmacology (including a pharmacopœia) fill up the remainder of the book except for a miscellaneous section which sets out standard equipment for a model branch dispensary, a medical trades directory, a list of manufacturers of surgical instruments and appliances, and calendars for all the years from 1935 to 1938.

We have no doubt that doctors working in India will continue to find this book useful.

## NEW INVENTIONS

### AN ASEPTIC FACE MASK

THE examination of chest cases entails a certain amount of risk from contamination by particles or droplets of infected saliva when patients speak or are asked to cough. When patients do not cover the mouth whilst coughing, infected material is expelled into the consulting-room, and not infrequently into the face of the examining doctor. The simple face mask, here illustrated, consists of a nose-

and ear-piece fitting in a similar manner to an ordinary spectacle frame, with a detachable mouth shield carrying a slip of filter paper. The patient is asked to put on the nose-piece which, with the light springs behind the ears, adjusts itself; the mouth-piece with its protective filter paper can then be slipped on, and this is effective in catching infected matter. Pieces of filter paper about 5×3 in. are prepared before a clinic; these can be easily slipped into the frame, and are as easily removed with forceps without soiling the fingers. If the ends of the paper are folded there will be no possibility of it slipping out sideways. The advantages claimed for this contrivance are: 1. It is simple and light (weight 1 oz. complete). 2. Easy to clean, being made entirely of silver-plated steel wire. 3. Easy to adjust without tying or stretching elastic bands, and does not interfere with patient's vision, talking, or breathing. 4. Can also be used for inhalant; a drop of Gutt. Cinnam. Co. (Brompton Hospital) is very soothing whilst mask is being worn.

The face mask has been made to my design by Messrs. Allen and Hanburys Ltd.

P. L. T. BENNETT, M.C., M.R.C.S., D.P.H.  
Tuberculosis Officer, Fulham.

### A FASCIA INTRODUCER FOR HERNIA REPAIR

THE necessity, in hernia operations, for an instrument of this type has arisen with the increasing use of fascial repair introduced by Gallie and LeMesurier. The operation formerly required between 40 and 60 minutes' work. The instrument which is described below will accelerate the operation 5 to 10 minutes for those surgeons who use and personally thread the Gallie needles. In practice it has two further advantages: (a) It diminishes tissue trauma in so far as it avoids the passage through the tissues of the mass formed by reduplicated fascia, suture material,

and the eye-end of the Gallie needle. (b) It enables the fascia during introduction to be touched by instruments only.

These two factors decrease the tendency to hæmatoma formation and sepsis. The principle is not entirely new in that a forceps, with the sharp ends curved in the long axis, has been used for this work by Keenan of Montreal. The arrangement of the blades at a right angle to the shaft, however, will be found more convenient in use. The closed blades are passed through the tissues, opened and the end of fascia grasped and drawn through in the desired situation. With practice this will be found a rapid method of introduction and will require little further time than that taken for the Bassini repair. I also use the introducer for inserting the non-fascial sutures for repair of femoral hernia by Lotheissen's method.

The instrument has been made for me by Messrs. Allen and Hanburys Ltd.

H. F. MOSELEY, M.Ch. Oxon., F.R.C.S. Eng.

LONDON: SATURDAY, APRIL 25, 1936

## STUDENTS AND TEACHERS

THE report<sup>1</sup> to the Treasury by the University Grants Committee, covering the six years since the last report was made, was published this week. It makes encouraging reading, and should inspire national pride in our university system, where the example of the old institutions has been wisely followed, where the lessons derived from the work of the newer bodies have been gratefully utilised, and where the State and individual donors have been open-handed in support. Considering that the period under review covers the unexpected prolongation of a grave financial depression which still exists, if with diminished force, it is a splendid omen for the intellectual, physical, and moral developments of the country that the Committee should be able to record, with full proof of their words, the substantial measure of progress which marks the present situation. There are on the grant list 16 universities and 3 independent colleges in Great Britain, while there may be added to the list the 2 technical colleges of Manchester and Glasgow. But certain of the universities, notably London, include a large number of separate units; under the heading of the University of London no less than 25 such bodies may be found, in which number is included the 13 medical schools, and it will be noted that medical education is here referred to only from a university standpoint. The Committee have inspected the buildings and equipment in connexion with all these centres, have interviewed representatives of the staffs, professorial and unprofessorial, and of the students, and with each and all have discussed the existing position informally. Such investigations lend a practical value to their words; these have no doubt been supplemented by returns submitted by the institutions, but however lucid and comprehensive such documents may be they must fail to give the accurate story in proper perspective which is derived from personal contact. Throughout the report the result of this interest in individual activities can be seen in the practical quality of the comments.

An increase in the total number of students has taken place wholly in England and Wales; the number of full-time students now stands at about 50,000, or 4500 more than six years ago, but while the figures for England and Wales show a rise in numbers there is a slight fall in the figures from Scotland, attributed mainly to the

abstention of women students. The allocation of the students over the main faculty groups is detailed in an appendix, and we see that numerous changes of their distribution in the various groups is marked by a sharp rise in medicine and a notable one in pure science. Six years ago in their last report the Committee recorded a substantial fall in the number of medical students, but the loss has now been more than made good. As a consequence the question of their residence is becoming a particularly vital one, and although it could hardly be expected that any special point should be made of the fact by the Committee, it will be gathered from the report that young men in training for medicine are benefiting from lavish expenditure which has taken place recently, not only on laboratories, libraries, research institutes, students' unions, but also on halls of residence and medical school buildings. Of the total number of all students at the universities and colleges under consideration (excluding of course the students at Oxford and Cambridge) the number living at home totals 22,000, of whom some 6300 are accommodated in halls of residence, but it is good to learn that, in spite of bad times and the severe competition of cheap lodgings, new residential halls are being opened, so that nearly 1000 more students now have residential provision than five or six years ago. To medical students this is of real significance. Where the medical students, either in London or elsewhere, are able to live at home in suitable circumstances, the need for the provision of hostels is not manifest, and it is arguable whether such students lose anything from pursuing their studies in the usual domestic circle. All to-day, however, regard university training as not only a means of acquiring knowledge, but as a medium for general culture and for the exchange of views, ideas, and aspirations leading to a philosophy of life. Many will think that the inestimable advantages of the community life are lost to the medical student who lives at home, and that for all medical students the provision of a hostel near the focus of their work would be an advantage. But life in the medical school must always be bringing all sorts of students in contact with each other in the course of the day's work, wherefore too much stress need not be laid upon the happy influence of the hostel. Looking at the whole question, we believe that there will be a predominant feeling that multiplication of hostels in connexion with the medical schools marks a step forward. And while it may be possible to obtain accommodation in lodgings at a lower figure than at many hostels, we have to remember that the number of students financially assisted in one way or another has now greatly increased. The Committee emphasise the extent to which an approach to the university institutions of this country is now made possible by scholarship allowances or eleemosynary grants.

Has the number of teachers increased in proportion to the increase of students? It would seem from the figures in an appendix that there has been an increase of 13 per cent. in the total numbers of the staff employed in the university institutions

<sup>1</sup> University Grants Committee. Report for the period 1929-30 to 1934-35. London: H.M. Stationery Office. Pp. 84. 4s.

of the country, a percentage which is rather larger than the percentage increase in the total number of students, though not when only the medical students are taken into consideration. But we are glad to learn that there has been a definite though modest improvement in the average salaries of the five grades of university teacher. How far the salaries of those concerned with the medical schools will benefit under average advancement is doubtful, but their work remains by no means overpaid while the responsibilities have greatly grown. Many a teacher in a medical school, when he thinks over his day's work, will envy the time, not so long gone by, when, save as a demonstrator, his routine duty could have been discharged by the delivery of set lectures and his fame as an educationist might have been established by his punctuality and his eloquence. He may also feel that the estimate now held as to the value of such discourses is unfairly low, knowing that he could communicate sound learning in this way. Undoubtedly many lecturers could thus prove of the greatest assistance to students, but the report indicates shrewdly why the lecture system has fallen into disrepute. Unless compulsory attendances will not be such as to maintain for the teacher an interest in fruitful labour; but if compulsory a spirit is introduced which is inimical to modern university training.

In reviewing a long and detailed report, while noting mainly certain of its medical messages, it is impossible to refer to much that has medical as well as general importance. But an expression of admiration is due for the wealth of information imparted, while the evidence of national progress in the greatest sphere of civilisation is heartening in the times we live in.

### VOLUNTARY HYPERTENSION

No simple explanation of "essential" hypertension is likely to be forthcoming. A promising approach has been through study of suprarenal secretion and attempts to correlate hypertension with an excess of pressor substances in the blood. Not only, however, has this line of inquiry proved disappointing, but it has revealed new difficulties regarding the relationship of the adrenal cortex to blood pressure. Thus it has been established that neuroblastomas of the suprarenal medulla do not result in hypertension, whereas chromaffinomas do so whether situated in medulla or cortex. Nevertheless, though no actual excess of pressor substances can be recognised in the blood of patients suffering from essential hypertension, it is not impossible that a relative excess may be brought about by deficiency of the hypotensive bodies, such as choline, acetylcholine, histamine, and vagotonine. This last substance, isolated from the pancreas, has a slow action compared with the better known parasympathetic stimulants, and is said to have given encouraging results in the treatment of hypertension.

The importance of psychical factors in the pathogenesis of hypertension has had much con-

sideration since ALLBUTT's pronouncement on the relation between mental anxiety and the development of granular kidney. AYMAN has described a "hypertensive personality," which is "dynamic" and "quick-tempered," and it is well known that emotional tension may be associated with a temporary increase in blood pressure just as it may affect visceral activity. ABRAMI, WALLICH, and BERNAL<sup>1</sup> now report that a number of subjects have been trained to raise their blood pressure (by as much as 100 per cent.) *voluntarily*. The rise is rapid and transient—lasting about a minute. The venous pressure, the intra-ocular tension, and the pressure of the cerebro-spinal fluid increase simultaneously, and it is also noticed that the internal temperature rises and the pupils are dilated. Curiously enough, the heart-rate is increased, despite the big rise in blood pressure. As an example of these remarkable observations the following figures may be quoted: a systolic pressure of 120 mm. Hg rose to 270–280, while in a few seconds the diastolic reading changed from 50 to 100 mm. Hg. The authors describe in addition changes occurring at the same time in other systems of the body, and mention that neither atropine, adrenaline, nor vagotonine affected the phenomena of "voluntary hypertension." Ergotamine seemed to delay the onset, and with strychnine the effect was obtained more easily and was of longer duration. The first to discover that he could raise his blood pressure at will was, it is stated, Mr. DINO GALARDI, aged 38; and he has been able to teach others to do it for themselves. Unfortunately, from the facts given, it cannot be understood just how the feat is performed, but it is emphasised that there is no question of straining or of generalised contraction of the body muscles.

It is to be hoped that Dr. ABRAMI and his colleagues will be invited to demonstrate their cases in this country.

### SCARLET FEVER IN HOSPITAL AND HOME

DURING the last few years our views about scarlet fever, from the epidemiological and clinical standpoint, have substantially changed, largely as the result of the work of the DICKS. SYDENHAM named the disease from the appearance of the rash, and from his time onwards the occurrence of a more or less characteristic erythema has been regarded as an essential element in the clinical picture. The rash is the visible result of the dilatation of skin capillaries by an erythrotoxic toxin produced by strains of a hæmolytic streptococcus implanted and growing upon the fauces. Since not all infections with causal strains result in the release of sufficient toxin to produce a clinically recognisable rash, this must be regarded as a by no means constant epiphenomenon. "Scarlet fever" is essentially an infective nasopharyngitis, and although there may not be agreement with all the views recently expressed in our columns by Dr. F. G. HOBSON,<sup>2</sup> it cannot be refuted—indeed,

<sup>1</sup> Abrami, P., Wallich, R., and Bernal, P.: *Presse méd.*, Feb. 26th, 1936, p. 321.

<sup>2</sup> THE LANCET, Feb. 22nd, 1936, p. 417.

it is admitted on all sides—that the hospitalisation upon a large scale of patients suffering from “streptococcal fever with a rash” has quite failed to control the incidence of the disease whether in its endemic or epidemic phase. The reasons are familiar to epidemiologists. With few exceptions, patients are not removed to hospital, or even isolated at home, unless the rash appears to clinch the diagnosis; the much more numerous and, because unrecognised, much more dangerous sufferers from sore-throats caused by the same organism, and the carriers, remain at large. Nevertheless, in spite of the prevailing mildness of the disease as generally conceived, the public insists, as a social service mainly, upon its hospitalisation.

After the patient's return home from hospital scarlet fever occurs in some other member of the household in 2 to 4 per cent. of cases. This has long been recognised, although in these “return” cases the source of infection is not necessarily the discharged patient. Genuine or not, return cases have led in the past, and on occasion still lead, to allegations of premature or improper release from isolation. We learn from the *Northern Despatch* that in a village in the north of England “widespread distress and something like a state of panic” exist among parents who are refusing to send their children to school “for fear of contact with cases recently discharged” from an isolation hospital in a neighbouring town. The main cause of complaint is that whereas the school managers are under the impression that the period of isolation for scarlet fever is at least six weeks, there is definite evidence of four children being discharged from hospital after not more than three weeks' stay. A counter-allegation of the “dirty condition” of the school as contributory to the outbreak, although illuminating, may be regarded as irrelevant for the present purpose, and the point at issue is whether the shortened period of detention resulted in return cases. It is the general experience of the medical superintendents of the large London fever hospitals who may admit and discharge during the year from one to two thousand scarlet-fever patients alone that a shortened period of detention of patients does not increase the return-case rate. It is an axiom of fever hospital practice that the scarlet-fever patient who is most likely to give rise to return cases is one who has been detained not for four weeks or less but, on account of some complication, for possibly fourteen weeks or more. Nearly ten years ago, as the result of evidence obtained from all over the country, the opinion was expressed<sup>3</sup> “that there is no good reason for prescribing a routine period of detention in hospital of more than four weeks in uncomplicated cases,” and the old six-week period which was based upon the now exploded belief in the infectivity of desquamation has long been abandoned by most fever authorities. There is no evidence that the adoption for the uncomplicated case, as a deliberate policy in properly spaced wards and not as a measure of exigency, of a period of detention of four weeks has had anything but a favourable

effect upon the return-case rate. Dr. H. STANLEY BANKS indeed advocates,<sup>4</sup> in conjunction with the intravenous injection of scarlet fever anti-toxin, a much shorter period. In a series of 1010 cases of scarlet fever thus treated the average duration of stay in hospital was 17.4 days and the return-case rate for the series 2.7 per cent.

The clues to the particular complaint of which we have spoken are to be found perhaps in a statement by the local medical officer of health. On the one hand, the isolation hospital was stated to be absolutely full and its medical superintendent therefore contended “that the mild cases, after three weeks, would do much better at home, owing to the congestion of the wards and the atmosphere being, naturally, full of virulent germs. . . .” On the other hand, it appears that most of the patients came from small two-bed-roomed cottages, and thus any measure of isolation after discharge was held to be impossible. Here then is a vicious circle—the demand not only for hospitalisation but for a fixed (and obsolete) period of detention; the packing of wards with patients who, under the circumstances, were better left at home since they would at least have been recognised as infectious and such precautions as were possible enforced; the efforts to make yet more accommodation in hospital by the early discharge, based upon necessity, of patients almost certainly reinfected by the hæmolytic streptococcus in the overcrowded wards; and thus the further dissemination of infection either in the inadequate homes or at school and the provision of fresh cases for the hospital. The time has surely come for local authorities to appreciate that adequate bed-spacing is the right of every fever patient; that overcrowding of wards in an attempt to cope with an impossible situation merely makes matters worse; and that under such conditions—be the stay long or short, six weeks or three—return cases, which can never be eliminated entirely, inevitably become more numerous. Outside London and other large cities and some smaller progressive towns, in how many fever hospitals in normal times, to say nothing of epidemic periods, is the minimum spacing of the Ministry of Health (12 feet between bed centres) adopted and adhered to?

WHEN, four months before his death last December, Dr. Griffith Evans celebrated his hundredth birthday, he was acknowledged as the father of the veterinary profession in this country. The University College of North Wales has decided to build an extension of the veterinary department in the school of agriculture at Bangor and to name it the “Dr. Griffith Evans memorial wing.” This will be an appropriate tribute to his memory, for he was the first lecturer in veterinary hygiene at the College, though the value of his contributions to science was not fully recognised until long after he made them. An appeal is being made to members of both medical and veterinary professions to subscribe to the memorial. Of the £4000 needed over £1000 has already been received, and the Ministry of Agriculture has promised to grant a pound for each pound of the first £2000 collected.

## ANNOTATIONS

### ESSENTIALS OF FRACTURE TREATMENT

THE treatment of fractures is not new. A recent writer has pointed out<sup>1</sup> that we have evidence of quite efficient treatment of fractures of the forearm at least 4500 years ago, though at this early date the management of fractures of the femur was not so good as it is to-day. But the principles were well recognised and established. Hippocrates used traction and countertraction for reduction and the modern plaster-of-Paris casts were represented by splints made of strips of cloth passed through molten wax. The necessity for padding bony points was recognised, and orthopaedic tables and pulleys were in use. Hippocrates insisted upon the necessity for prompt reduction, advice which is too often disregarded, saying "extension of fractured or dislocated bones is not to be delayed to the third day, but is to be carried out on the first day." All that we have really gained since his time is the power of safe open reduction and of skeletal traction. Hippocrates insisted that broken bone-ends should be brought into apposition and that no movement should be allowed until the fracture became solid. If we add to this that all movements which do not endanger this fixity should be encouraged we have the three great principles in the modern treatment of fractures. These principles can be carried out if the practitioner has the common sense of everyday mechanics, a knowledge of anatomy, especially the anatomy of muscular action, a smattering of physiology which informs him of the advantages of elevation and the drawbacks of pressure upon bony points, and an acquaintance with the use of a few standard splints, particularly with the management of plaster-of-Paris. That there is no best way for treating any particular fracture is abundantly evident to anyone who visits different fracture centres of note. In each he will find excellent results obtained, but by very different methods. The factor common to all of them is a personnel which adheres strictly to the principles laid down above and is endowed with the necessary qualifications for carrying them out. Fractures must receive as much attention as any abdominal operation; a daily, or more than daily, inspection and control alone will ensure a uniformity of good results. In general surgical clinics, where such conditions prevail, the fracture work is fully of the standard of that in special clinics; indeed, it is likely to be of a higher standard, because of the greater breadth of outlook of general surgery. It is certainly true that the efficient treatment of fractures depends far more upon the quality and temperament of the surgeons who undertake the work than upon the possession of any special knowledge or indeed of any special skill. Effective methods of treating fractures have been worked out years ago, but not everyone can put them into practice.

### THE ACTION OF CYCLOPROPANE

WRITING on the use of cyclopropane in obstetrics, R. T. Knight<sup>2</sup> brings out the difference between its action and those of the other general anaesthetics. Cyclopropane, he maintains, has as its chief characteristic that the vital centres and the parasympathetic system are left unaffected long after the desired effects have been produced. It is well known by all who have used the agent that the slowing down and actual stoppage of breathing under cyclopropane

have not the sinister significance they usually bear during general anaesthesia. The quietness, and even absence, of respiratory movements of a patient under cyclopropane are not associated with the dilatation of the pupil or duskiess of complexion which are seen in respiratory depression caused by other agents. This is because the respiratory arrest is not due to any central action but is merely the result of inhibition of motor neurons in the cord and of relaxation of muscles of respiration. In accordance with this paralysis of reflex arcs brought about by cyclopropane the intestine lies small and contracted in the abdomen, just as when an endothelial injection of an analgesic has been made. Knight also shows that, so far as his comparatively small series is evidence, the blood loss during childbirth is less under cyclopropane than under other anaesthetics.

### EFFECTS OF RADIUM ON THE EYE

THE radiation treatment of malignant disease in the neighbourhood of the eye presents certain special difficulties. In a communication to the Ophthalmological Congress on April 3rd Mrs. Philippa Martin, F.R.C.S., described the investigation into the effects of irradiating the eye carried out by her while holding the Percival Alleyn scholarship at University College Hospital. She has previously<sup>1</sup> described the early and late effects. First a conjunctival reaction appears with chemosis, usually at the lower fornix, accompanied by a watery discharge which may become muco-purulent; pain is not a pronounced feature. Late effects include scarring of the conjunctiva, obliteration of the puncta, chemosis, and corneal ulceration. Iritis is an early complication which suggests severe injury, and may be followed by necrosis of the cornea or cataract. Mrs. Martin now gives a more detailed description of radium necrosis as seen in the eye, particularly the effects of radium on the cornea, and makes valuable suggestions as to treatment. Radium necrosis of the cornea may occur, she says, in any case in which intensive irradiation is used in the treatment of adjacent malignant disease. The time of onset varies with the intensity of irradiation. The reaction is much more severe and early after repeated irradiation or in the presence of sepsis, particularly when the infection has been intensified by surgical intervention. The earliest sign of damage to the cornea is a diminution of sensation—the response to light cotton-wool touch being slower than in the normal eye. After a few weeks or months the cornea may lose its polish, and in a few hours a small superficial ulcer may appear and spread slowly. The condition may be arrested at this stage or it may progress even to perforation, but even in these cases infection of the whole eye is slow to develop. The process of repair may not begin for months and in any case will be slow. It can be expedited or at least encouraged by methods which Mrs. Martin outlines. As soon as the first signs of ulceration appear a mydriatic should be used and the eye bandaged. This should not be a routine procedure in the early weeks following radiation even if pain is present, because the swelling of lids and conjunctiva makes the estimation of tension impossible. Where intense radiation is planned a mydriatic should be used to dilate the pupil beforehand and the exact size noted for purposes of comparison. In these cases it is often advisable to stitch the lids together during

<sup>1</sup> Magnuson, P. B.: *Surg., Gyn., and Obst.*, Feb. 15th, 1936, p. 276.

<sup>2</sup> *Anaesth. and Analges.*, March-April, 1936, p. 63.

<sup>1</sup> *Transactions of the Ophthalmological Society*, 1933, *liii.*, 246.

radiation. When radium necrosis appears to be spreading a tarsorrhaphy should be done, with special care in view of the delayed healing of irradiated tissues. Even when the ulcer perforates it is not always necessary to remove the eye; the infection is usually mild and healing may occur. The cases recorded were mostly treated some years ago with interstitial radium needles and the dosage is given in milligramme hours. It is encouraging to find that the damage to the eye was not as a rule very severe, though the dosage given was necessarily high.

During the last three years several patients have been irradiated by the 1-gramme unit without severe reaction. In this connexion Mrs. Martin points out that any attempt to protect the eye from the deleterious effects of irradiation by the use of a metallic screen is dangerous; the screen acts as a source of secondary radiation and increases the damage to the eye. It would seem that we have here a possible method of treating malignant neoplasms near the eye without necessarily destroying function. In the past many such neoplasms have been allowed to advance to an extent where both sight and life were lost in the attempt to save the eye.

#### A NEW CLASSIFICATION FOR MEDICAL LIBRARIES

Books on special library classification are rare, yet the subject concerns not only librarians but also the many who have occasion to visit libraries and wish to make the best possible use of them. Mr. Barnard has set out in a handy volume<sup>1</sup> the result of the experience he has gained in building up a fine collection of medical literature at the London School of Hygiene and Tropical Medicine. In a short explanatory introduction Mr. Barnard points out that he has devised his scheme of classification on an essentially practical basis, and in this respect he has undoubtedly made improvements on the Universal Decimal Classification (U.D.C.). The adoption (following Cutter) of an almost pure alphabetical notation, instead of a numerical one, certainly shortens the symbols for the same minuteness of subdivision, but at the same time some of the mnemonic value of the latter is lost. Another difference is that Mr. Barnard had adopted (independently) the method of specific entry in use in the Boston medical library—that is to say, all works are entered under one subject heading no matter what the aspect. The anatomy of the thyroid, for instance, is entered with physiology, pathology, and surgery of this organ under U Q O, whereas in the U.D.C. a definite line is drawn between organs in health and in disease, the biochemistry and physiology of thyroid being given the number 612.44, and the pathology and treatment of thyroid disease 616.44. The only real criticism of Mr. Barnard's scheme, from the point of view of a general medical library, is that, out of 26 main alphabetical divisions, he allots as many as 8 letters (H-O) to the sections of Bacteriology, Parasitology, and Medical Zoology, whilst an important division such as Midwifery is put in a subdivision U W. For libraries used chiefly by laboratory research workers this allocation is no doubt justifiable, but in any library intended for clinicians, the division U (Specialities of Medicine) is liable to become hypertrophied. Minor criticisms concern the logical arrangement and the placing of related subjects in the

scheme. Preventive Medicine (S), for instance, might be expected to precede Diagnosis and Therapeutics (Q and R). Apart from such details, however, this new alphabetical classification is certainly practical, and many medical librarians in the future are likely to adopt it; others may even think of exchanging existing classifications for this system. Even ardent and prejudiced "decimalists" are likely to admit that this new classification compares not at all unfavourably with the U.D.C.

#### EXPERIMENTAL MYOCARDIAL ISCHÆMIA

WHILE it is accepted that the essential anatomical lesion of nearly all cases of effort angina and myocardial infarction is atheroma of the larger coronary arteries, aggravation of ischæmia in the former case has been thought to occur as a result of vasoconstriction; which, experimentally, can be brought about by vagal stimulation. Myocardial ischæmia is not generally recognised in man as a result of vasoconstriction alone, but G. E. Hall, G. H. Ettinger, and F. G. Banting have now, by injecting acetylcholine, the chemical agent through which vagal and all other parasympathetic action is effected, produced changes in the myocardium of dogs.<sup>1</sup> Evidence of the temporary effect of the drug at the time of the injection was present in salivation, tachycardia, dyspnœa, and peripheral vasodilatation. After a time systolic murmurs appeared and the electrocardiogram showed changes; terminally there were signs of cardiac failure, the animals dying with extreme dyspnœa or cyanosis, or in some cases unexpectedly. Sections of the heart revealed varying degrees of pathological changes, those in older dogs being more severe; there was hyaline change in the medium and smaller arteries, fibrosis in the media, and in some cases thrombosis in the lumen. The myocardium showed recent infarcts and areas of fibrosis. In the young dogs there were myocardial but no arterial changes. The authors point out that the most severe vascular changes are found in just those areas where vagal action is unopposed by the sympathetic—namely, in the medium and smaller arteries.

Another report concerns the action of Euphyllin in opening up a collateral circulation after experimental coronary occlusion. W. M. Fowler, H. M. Hurewitz, and F. M. Smith found<sup>2</sup> that, after tying the anterior descending branch of the left coronary in the dog, the area of cyanosis which then appeared on the heart wall could be considerably reduced by an injection of this drug, which is a combination of theophylline and ethylene-diamine, the effect persisting for at least one and a half hours. A distinct fall in blood pressure occurred after the injection, but this could be almost eliminated by giving it slowly combined with a hypertonic glucose solution. The late effects of the ligature in dogs which received the drug daily for a period of three weeks were found to be much less extensive than in controls; at autopsy the infarcted area was definitely smaller in the former group. On the clinical side an effective action by euphyllin on symptoms suggesting coronary disease is claimed<sup>3</sup> by F. M. Smith, H. W. Rathe, and W. D. Paul. Of four cases of congestive failure in which it was tried two showed improvement coinciding with the administration of the drug; the control period however was short. The results in 100 cases with paroxysmal dyspnœa, angina of effort, and acute

<sup>1</sup> A Classification for Medical Libraries. By Cyril C. Barnard, B.A. Lond., Univ. Lond. Dipl. Librarianship, F.L.A., Librarian, London School of Hygiene and Tropical Medicine, London: Percy Lund, Humphries and Co., Ltd. 1936. Pp. 142. 10s. 6d.

<sup>2</sup> Canad. Med. Assoc. Jour., January, 1936, p. 9.

<sup>3</sup> Arch. Internal Med., December, 1935, p. 1242.

<sup>4</sup> Ibid., p. 1250.

coronary occlusion were favourable in 72, doubtful in 11, and negative in 17. Assessment of the results of treatment of these symptoms, as with most paroxysmal conditions, is difficult, and while Smith and his co-workers were careful to observe patients when the drug was withheld, no placebo appears to have been given at these times. It may be recalled that in the fully controlled study<sup>4</sup> of Evans and Hoyle on angina of effort the results obtained with a placebo were superior to those with euphyllin.

#### ANORECTAL GONORRHOEA IN WOMEN

THE medical mind is so accustomed to associate gonorrhœa with the genito-urinary tract that the possibility of extragenital infection is apt to be forgotten. It has long been recognised that this type is commonest in the anus and the rectum in the female, involvement of which is, as a rule, secondary to infection of the usual sites. Nevertheless it is an aspect of the disease that has received comparatively little attention and which presents a number of unsolved problems of considerable potential importance. There seem to be two reasons for this neglect. The symptoms of anorectal infection are generally either absent or so slight that the patient's anxiety is not aroused and no complaint is made, and there are seldom any external signs. Secondly, many who treat gonorrhœa in the female believe that the infection in this area is self-limited, and that unless there are serious symptoms and signs no treatment is required. This attitude is not necessarily due to carelessness or lack of interest, but may be due to the difficulty of persuading some women with gonococcal infections to continue with treatment after their symptoms have subsided. If they are subjected to additional annoyance and discomfort from manipulation and instrumentation of the anal canal, some of them will cease to attend. Whatever the reason, it is probable that the majority of women that are treated for gonorrhœa and passed as free from infection never undergo clinical and bacteriological examination of the anal canal and its contents.

Most of the reports on this subject have come from abroad, but Clements and Hughes<sup>5</sup> have shown that the condition is equally common in this country. Among 160 women in whom genito-urinary gonorrhœa was present or suspected, 69 had anorectal involvement as shown by smears or culture, or by both. The latter proved to be more effective in isolating the gonococcus, but the best results were obtained by combining the two methods. Observation without treatment was carried out in 10 of their cases for periods not exceeding seven months and this convinced them that the disease is not self-limited. Brunet and Salberg, of Chicago,<sup>6</sup> have now reviewed the results of their investigations over three years, and their series includes 250 cases of anorectal infection, forming 42 per cent. of all their female patients who were found to have gonorrhœa. Only 25 patients complained of symptoms which were referable to the anal infection, and in most of these the symptoms were not severe. The diagnosis was made by means of smears taken from the anal contents, and the presence of intracellular Gram-negative diplococci, together with 25 or more pus cells per field, was accepted as evidence of a gonococcal infection. As a control, smears were taken from more than 200 women without evidence of past or

present infection, and in these no Gram-negative diplococci were found; pus cells were discovered only occasionally and then not more than 5 to the field. Cultural methods proved to be too involved and inconclusive, and therefore of no practical value as an aid to diagnosis. On proctoscopic examination of 111 of the infected patients, 40 showed no changes in the anal and rectal mucosæ. In the remainder there were varying degrees of inflammatory change but nothing which could be described as characteristic of this infection. Complications were uncommon; there were no cases of rectal stricture, only 4 of perineal abscess, and 3 of rectal fistula. After treatment, mainly with medicated suppositories, hot sitz baths, and mineral oils by mouth, cure was judged to have been obtained in an average time of 19 weeks. It was found possible to re-examine 59 patients, who had defaulted, after intervals varying from 6 months to 2 years; all were symptomless, but in 10 the smears were positive; in the remaining 49 the smears were negative. These investigators adhere to the accepted view that infection occurs from the vagina, probably by the discharge passing over the everted anal mucous membrane during the act of defæcation. They believe with Rosser<sup>7</sup> that the anal crypts (sinuses of Morgagni) form ideal reservoirs for the infection, which may persist in the anal canal long after the urethra and cervix are clear.

The question as to the self-limitation of these infections when they remain untreated does not appear to be settled by the evidence at present available, but it is quite certain that the gonococcus can persist in the anus and rectum for considerable periods. If, as Brunet and Salberg believe, the urethra and cervix may be reinfected from this site, anorectal gonorrhœa must be regarded as one possible cause of the frequent and lamentable cases of "recurrence" and "re-infection" which occur among women who remain under observation after treatment for genital gonorrhœa. There is no evidence to show that infection in this site can act as the initial focus in the metastatic infections of gonorrhœa, but it is important that the possibility should not be overlooked when the origin of infections of this type cannot be traced. The disagreement as to the value of cultural methods for isolating the gonococcus, which is evident in these reports and in many others relating to gonorrhœa, is an example of the extraordinary lack of unanimity of opinion on many fundamental points associated with the study of these infections. There can be no doubt that many pathologists have failed to overcome the inherent difficulties of the artificial cultivation of the gonococcus, and that the quality and value of clinical work in gonococcal infections suffer accordingly.

#### TELEPHONES FOR THE DEAF

DEAFNESS is usually a bar to easy conversation on the telephone, and may deprive the sufferer of many of its benefits in society and in business. We are glad therefore to hear that the Post Office is now prepared to install a new type of instrument in which the volume of sound may be increased, according to the listener's requirements, by turning a control knob. This special telephone, with its speech-amplifying equipment, is said to be effective in all but extreme cases of deafness, and it is equally useful for local and for long-distance calls. A correspondent of the *Times* (April 18th) writes that though she suffers from almost complete deafness,

<sup>7</sup> Rosser, C.: *Texas State Jour. Med.*, 1933, **xxix.**, 390.

<sup>4</sup> *Quart. Jour. Med.*, July, 1933, p. 311.

<sup>5</sup> Clements, P. A., and Hughes, K. E. A.: *THE LANCET*, 1935, **ii.**, 13.

<sup>6</sup> Brunet, W. M., and Salberg, J. B.: *Amer. Jour. Syph.*, January, 1936, p. 37.

she is now able to hear the voices of her friends on the telephone—a pleasure previously denied her for very many years. The amplifying equipment is contained in a small cabinet which can easily be accommodated in any out-of-the-way position near the telephone, and the instrument can be fitted on any installation served by an automatic exchange, or by a manual exchange of the type provided in the more populous areas, at an extra charge of 10s. a quarter.

### MINISTERING TO THE SICK

THERE can be no sharp line drawn across the map of medical treatment which attempts to allot provinces on the one side to exact therapeutics and on the other to the various attentions on physical and moral well-being of patients such as fall under the headings of religious support, mental guidance, sympathy in family troubles, or the provision of diversions. The doctor's work may be assisted by the priest, almoner, and hospital visitor, and the medical profession knows very well the wide influence for good and the favourable impulses towards restoration that follow upon the intelligent aid of sympathetic persons outside the professional rank. And the priest may occupy the honourable and peculiar position of adjutant in the direct medical treatment. In domiciliary medicine this can be well observed where the patient belongs to the priest's flock, but in the hospital where the patient is personally unknown to the priest the value of religious ministrations has been much debated. To many his presence round the bedside appears to be nothing but a nuisance. He is needed, they would say, neither in diagnosis nor treatment, and being no expert in many social difficulties it cannot be expected that his coöperation can be of any practical value. Dr. Richard Cabot and the Rev. Russell Dicks, B.D., have written an interesting book setting out the claims of the minister to be present in the sick-room, paying regard to the limitations of his knowledge, while pointing to the unlimited value which spiritual assistance may be to the patient.<sup>1</sup> The authors believe profoundly in the value of coöperation between the doctor and the minister in hospital work—they only consider in any detail the patient in the institution—and they propose to show that the aims which will call the minister to the bedside are to counteract the evils of specialism, and to give devotion and spiritual care such as only religion can inspire. By the words counteraction of specialism it is implied that medical treatment, however broad, is of a special character, while social and spiritual diagnosis in the presence of disease require qualities which no doctor, unless by accident, can attempt to offer. Criticism of a work written with deep sincerity is made difficult because it is not possible to assess devotional belief as a method of treatment in the same sort of way in which therapeutic procedures and operative methods can be submitted to judgment. One does not know how far such belief is present in any given case of improvement or recovery. The dual treatment, as suggested in the book, comes into play mainly in institutional treatment, where it may be thought to be of less value than in the home, and where the circumstances of environment are so favourable to moral as well as physical change that the actual cause of any alteration for good must always be uncertain. The part allotted by the authors to the minister is magnificent, and brings

about with it the discharge of difficult and ungrateful duties: to discharge them he must be an extraordinarily endowed person, possessing faith, intuition, delicate tact, broad sympathy, scriptural knowledge, familiarity with topical literature. All these qualities are in the examples of religious treatments set out, and as we are apt to endow the ideal doctor in talking of him with many of them, we must not grudge them to the ideal priest. Each may hope to display them, and in their exhibition may find as a result physical and moral betterment of the patient in accordance with the well-known influence of mind on body. But the authors suggest that in institutional life the priest would find a proper rôle in supervising the amenities of the institution in a way that in this country would bring him into collision with the heads of the managerial and nursing departments. Every doctor knows the store that is set by many patients upon the ministrations of the clergyman and knows also their value from the therapeutic point of view in certain cases, even while unable to assess that value in any exact terms or predict its display in any particular case. But it seems highly doubtful if either the medical staff or the lay management would regard the visiting clergyman as a fitting mediator in staff troubles. If the secretary of the hospital and the superintendent of the nurses chose to consult him on points of difficulty no doubt they might benefit by his advice, but to interfere in these departments is not comparable to helping the sick; it is comparable to advising the doctor as to medical treatment, and that we do not commend. But we can commend the book to which we are referring as one dealing with questions that are often before the medical profession in this country, if not in exactly the same form in which they have presented themselves to the able and sincere American writers.

### WILLIAM B. COLEY

THE death in New York on April 16th of William Bradley Coley at the age of 75 years removes a forceful figure from American surgical life. In this country his name is chiefly associated with a fluid for the relief of inoperable cancer. Moved by Paget's observation that malignant tumours occasionally diminish or disappear after an attack of erysipelas Coley worked assiduously on the action of living streptococci in sarcoma and 45 years ago he published an extensive series of cases of inoperable sarcoma which had shown benefit after injection of the combined toxins of *B. prodigiosus* and *Strept. erysipelatis*. Other surgeons had like experience of benefit in 2 to 4 per cent. of such cases, and in 1910 Coley's fluid was included in the list of non-official remedies compiled by the American Council on Pharmacy and Chemistry. Coley never ceased to develop this treatment and ten years ago he and his brother recorded the completed story of 55 cases of sarcoma in which the diagnosis had been confirmed by well-known pathologists. A few months back the Council on Pharmacy in reviewing the whole of the evidence concluded that the combined toxins of erysipelas and prodigiosus may play a significant rôle in preventing or retarding malignant recurrence or metastasis, and on occasion may be curative in hopelessly inoperable neoplasms. But Coley was not a man of one idea. He held the chair of clinical cancer research at Cornell and was always a seeker after truth. His own papers are models of clinical presentation and so fully documented as to command attention from other workers in the same field. He was on the staff of the Hospital for Ruptured

<sup>1</sup>The Art of Ministering to the Sick. By Richard C. Cabot, M.D., and Russell L. Dicks, B.D. London: Macmillan and Co., Ltd. 1936. Pp. 384. 12s. 6d.

and Crippled in New York, and it was in connexion with the operative treatment of hernia that his name first came into prominence. Last month, in the *American Journal of Surgery*, he told the story of the radical cure of hernia during half a century. He had friends in many countries, for he was a man of wide general knowledge, interested in men and affairs. Evidence of this was afforded by his reception last October when the honorary fellowship of the Royal College of Surgeons of England was conferred upon him and he was later entertained by Glasgow surgeons. His country home in Sharon became a meeting-place for his European friends. There was determination and pertinacity in his nature which enabled him to do what he did in spite of the acromegaly from which he was a lifelong sufferer and the ulcer which necessitated gastro-enterostomy—performed under local anaesthesia. For many years he was consultant to one of the large American railway companies.

#### POST-OPERATIVE GANGRENE

Liedberg of Lund reports<sup>1</sup> two further cases of the rare post-operative gangrene of the skin, one following operation for gangrenous appendicitis, and the other complicating suppurative mastitis. The onset was, as usual, gradual and the progress unrelenting, "centimetre by centimetre, week by week." The ulcerating edge just outside the frankly gangrenous margin [gave rise to the same intense pain and tenderness as has been described by other authors, and the extending margin showed the three typical zones, of blackish gangrene, bluish-red, and bright red inflammation. The wound in which gangrene followed appendicectomy was clean-stitched, but the appendix was definitely gangrenous, so that the skin edge may very easily have been infected. In most reported cases the wounds have been drained, and this is of importance because the condition is generally attributed to symbiotic invasion by a streptococcus from the intestine (or at any rate from the peritoneal cavity) and a staphylococcus from the skin. In view of this supposed aetiology, the occurrence of the disease in the breast is somewhat unexpected; and indeed all previous reports have been of gangrene after operations on the serous cavities, either for empyema, or for diseases of the stomach or intestine. In the case of mastitis here reported the patient developed a swelling like a carbuncle, which was incised. The pain was severe and the wound broke down into an ulcer involving the inner and upper part of the left breast and the size of a child's hand. The process spread rapidly in the three weeks following, but was at once arrested by excision of the whole of the altered skin with the diathermy knife. The pain was completely relieved by the operation, and healing began; and though a subcutaneous abscess had to be opened about three weeks later, there was no further gangrene. The temperature was moderate throughout. The other case, in which the gangrene followed appendicectomy, was fatal; but apparently excision of the wound was not so thorough. Complete excision, extending out into the healthy skin, seems to be an almost certain cure, and no other measure is worth considering. Liedberg quotes Meloney as finding very little to choose between excision by the scalpel or the cautery knife. He himself rather prefers the cautery because its use prevents great loss of blood. A mixed growth of staphylococci and streptococci was obtained in the appendix case, but only staphylococci in the

one with mastitis. Liedberg gives a useful résumé of 40 cases recorded before his own.

#### TESTS FOR VITAMIN DEFICIENCY

IN our last issue Dr. L. J. Harris and Mr. P. C. Leong described a new test for vitamin-B<sub>1</sub> deficiency in human beings. As in Harris and Ray's test for vitamin-C deficiency, the patient is given a large dose of the vitamin and the urine is examined to find out how much of it is excreted. If a person has had ample supplies of the vitamin in his diet his tissues will be "saturated" and he will excrete a large proportion of this test dose; on the other hand, if he is suffering from a deficiency his "unsaturated" tissues will retain more and he will excrete less. Dr. Harris believes that these tests provide good objective evidence of specific deficiencies, and in a further article on p. 966 he argues that the methods now available should enable us to arrive at much more satisfactory standards of sound nutrition. To this end he wants to see surveys undertaken to discover the incidence of definite nutritional defects throughout the country; but the question arises how far the tests he enumerates can yet be taken as established. Confirmatory reports on the urinary excretion test for vitamin C are continually appearing, but the similar test for vitamin B<sub>1</sub> is, of course, only in its infancy, and the validity of the Jeans and Zentmire's photometer test for partial vitamin-A deficiency has not been fully accepted. Fortunately its authors have just furnished further confirmation<sup>1</sup> of their first observations, published in 1934, on the use of the photometer for the ascertainment of night-blindness. Failure in adaptation to darkness is regarded as one of the earliest symptoms of vitamin-A deficiency, and though it is not entirely specific its dependence on vitamin-A lack in any given case or series of cases can always be proved by giving this vitamin and noting the results. The photometer test is now placed on a far more satisfactory basis as a criterion of vitamin-A insufficiency by Jeans and Zentmire's study of the incidence of night-blindness in a widely varied group of Iowa school-children, including rural and village children, and also urban ones from various economic levels. The observers were astonished at the high percentage (36), even among rural children, who failed to react normally, while among the poorest urban children only 11 per cent. were regarded as normal, the village and better-off urban children showing intermediate results. Administration of halibut-liver oil or carotene brought back the photometer reaction to normal in all but a tiny fraction. The specificity of the photometer test as a criterion of vitamin-A insufficiency was thus corroborated and the existence of a widespread slight deficiency of this vitamin, at least in the State of Iowa, seemed to be established.

WE regret to announce the death last Tuesday of Dr. Henry Jasper Cardale, chairman from its inception of the London Panel Committee.

ON Thursday, April 30th, Prof. W. W. C. Topley, F.R.S., will give the first of the five William Withering lectures, on the chemical and biological aspects of immunology, which he and Mr. Percival Hartley, D.Sc., are delivering at the University of Birmingham. Prof. Topley will also lecture on May 14th and 28th, and Dr. Hartley on May 7th and 21st. All the lectures will be at 4 p.m., and members of the medical profession and students are invited to attend.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

### XCVIII.

#### PROGNOSIS IN FOOD POISONING

SINCE food poisoning is not a definite entity and hardly a definable conception it is only possible to discuss prognosis in the light of the different types of causation.

##### Poisoning by Chemical Substances

The chief mineral salts which give rise to poisoning are those containing lead, arsenic, antimony, zinc, copper, and tin. As regards symptoms they mostly fall into two groups. In one there is continued absorption of small quantities of the toxic metal, such as may occur with lead poisoning associated with beer or cider contaminated with lead. The prognosis has to take into account the risk of damage to vital organs such as the kidneys, this being more important than risk to life, although deaths have occurred in such outbreaks. The two main considerations are the dosage and whether the substance exerts a cumulative effect.

Poisoning associated with the ingestion of *arsenic* is naturally always serious both from secondary effects and risk to life. In the Manchester outbreak of arsenical poisoning from beer there were at least 6000 persons attacked and over 70 deaths were recorded. When the toxic substance is an acute gastro-intestinal irritant, as occurs for example with lemonade made in vessels treated with a soluble antimony salt, or with an acid fruit acting upon zinc retainers, the dose ingested sets up diarrhoea and vomiting and may be alarming from the prostration caused, but the symptoms are of limited duration and deaths are practically unknown, while no late harmful results are to be anticipated as there is no absorption of the mineral.

Occasionally rare types of widespread chemical poisoning occur. One of the most extensive was that due to the use of adulterated extract of Jamaica ginger, mostly in U.S.A. in 1930, involving some 15,000 cases, the toxic agent being tri-ortho-cresol. The actual case-mortality was not ascertained, but it was high, while the late effects were disastrous, resulting in extensive atrophy of muscles and nerves. Recovery when it did occur took from one to two years.

Alkaloidal poisoning may occur. This may be accidental, as when belladonna plant is mixed in with sage by mistake for stuffing. The prognosis depends on the dose and the rapidity of efficient treatment. Allied is mushroom poisoning, and the most important factor affecting prognosis is the species of mushroom and to a lesser extent the dose. With *Amanita phalloides* the mortality-rate is at least 50 per cent.; with *Amanita muscaria* recovery is usually rapid and complete and deaths are comparatively rare. Poisoning with *Helvella esculenta*, although it gives rise to jaundice and late hæmoglobinuria, has a low mortality-rate.

Another peculiar type of food poisoning with a considerable mortality is from *mussels* which have become poisonous from causes not yet completely understood. The most extensive recent outbreak which has been investigated is that on the Pacific coast of California in 1927 with 102 known cases and 6 deaths. The poisonous substance was a toxin of non-bacterial origin.

In general, prognosis depends upon the nature of the toxic agent, modified by the amount ingested and the promptness and efficiency of treatment.

##### Bacteria which Produce Gastro-intestinal Irritation

The commonest type in this country is due to various members of the salmonella group. Those members which cause food poisoning act as gastro-intestinal irritants and produce toxins which cause severe diarrhoea, vomiting, and prostration. They act, therefore as cleansers of the alimentary tract so that apart from treatment recovery after a few days is usual. The actual mortality-rate is low, only 1.2 to 1.3 per cent.

The interesting point as regards prognosis, even when the living bacillus is introduced, is that the usual course is purely the action of a gastro-intestinal irritant, without any circulation of the bacillus in the blood stream. Direct blood examinations are invariably negative even when the organism is very abundant in the faeces. In this they differ widely from paratyphoid fever (also due to a salmonella strain). On the other hand, in all fatal cases of salmonella food poisoning it is quite easy to recover the bacilli from the spleen, liver, and other internal organs. These facts suggest that the usual course in salmonella food poisoning is for the bacilli to be restricted to the alimentary tract and as such involves a very small risk to life, but should they establish a parenteral infection and set up a septicaemia there is grave risk of the case terminating fatally. Apart from this risk, which mortality figures show is not great, there may be long-continued prostration without permanent ill-effects.

Another group of food-poisoning cases have been shown within the past few years to be due to toxins produced by staphylococci and in rarer instances to streptococci. So far nearly all the recorded outbreaks have been in America. The poison here is an enterotoxin, is effective in filtered sterile cultures, and is only produced under certain conditions, not yet fully understood. The poisons act as gastro-intestinal irritants usually comparatively mild in character so that the symptoms are not severe and complete recovery always occurs.

Another important group, because fairly common, is one in which the poisoning is entirely associated with bacterial toxins without the presence of any living bacilli. There is no unanimity of opinion as to the bacterial source of the toxins, the evidence that they are associated with salmonella strains not being accepted by all workers. Whatever their nature they are a characteristic group of importance from the point of view of prognosis. The toxins being preformed, and all present at once, the symptoms are often very abrupt in origin, very severe in character, and sometimes alarming. The patients think they are going to die, but never do unless at the extremes of life or debilitated from disease. They rapidly and completely recover, apart from anything much in the way of treatment. The actual case-mortality from a large series is about 0.5 per cent.

##### Bacterial Poisons Acting Mainly on the Nervous System

The only food poisoning of this type is botulism. Here the fatality-rate is exceedingly high, between

60 and 70 per cent. In the Loch Maree outbreak all the 8 persons who took out and ate the wild duck paste sandwiches died. With such a high mortality it is of value to consider the factors which make for a lower rate. In man the cases may be caused either by type A or type B *Cl. botulinum*, but the toxins are of equal potency. The condition is one of intoxication not a bacterial infection, so the amount of ingested toxin is the primary factor and dosage is important. Like *B. diphtheria* the organism produces a true toxin outside the bacterial cell and the antitoxin is equally effective. The two types produce different toxins, and the antitoxins are specific and are useful only for the same type. There is not time to type the organism even if it can be

isolated, so a polyvalent antitoxin must be used, preferably injected intravenously. Animal experiments demonstrate its marked efficiency if given at the time or soon after the ingestion of the toxin; it is of little or no value if delayed long after the onset of the first symptoms. It must be available, polyvalent, and given early. Unfortunately these conditions are difficult to meet and this makes the prognosis bad. No other treatment seems to be of any use. The two factors affecting prognosis are the amount of the dose ingested (and this is not important in practice because the poison is so toxic) and the promptness of diagnosis with effective antitoxin treatment.

WILLIAM G. SAVAGE, M.D., B.Sc.  
Medical Officer of Health, Somerset.

## SPECIAL ARTICLES

### A PROGRAMME FOR NUTRITION SURVEYS

BY LESLIE J. HARRIS, Sc.D., D.Sc.

MEMBER OF THE SCIENTIFIC STAFF OF THE MEDICAL RESEARCH COUNCIL

(From the Nutritional Laboratory, University of Cambridge and Medical Research Council)

CONSIDERABLE discussion has taken place recently as to the most suitable formula to be used in the assessment of malnutrition, as based on measurements of physique (that is, on data for weight, height, and/or age).<sup>1</sup> Some workers have urged the desirability of substituting measurements of physical performance for those of physical development.<sup>2</sup> Others again would rely more exclusively on clinical appearance.<sup>3</sup>

It is apparent, however, that all these methods have serious limitations. In the first place they may easily fail to detect the earlier and less obvious stages of undernutrition. Secondly they may give inadequate information about the specific nature of the deficiency or deficiencies in question—more especially when the deficiency is partial or moderate only.

The above criticisms may at first sight seem rather sweeping, but one may illustrate their truth by reference to the results of a number of recent inquiries in which the incidence of undernutrition has been determined by more specific methods.

The observations of Helen Mackay on the prevalence of nutritional anaemia may be chosen as the first example. She observed<sup>4</sup> that 70 per cent. of a group of poor-class bottle-fed babies in London suffered from some degree of nutritional anaemia; the deficiency was associated with an increased morbidity-rate, so that when the anaemia was cured by provision of extra iron the morbidity-rate was duly diminished. A similar high incidence of anaemia has been observed elsewhere—e.g., for mothers at Aberdeen<sup>5</sup> and at London.<sup>6</sup> The important point to realise is that this specific evidence of malnutrition was detected only after laboratory test, and that reliance on the more cursory clinical methods or on "weight ratios" would have failed to reveal unmistakably the presence of undernutrition in most of these individuals.

As a further example, the figures relating to the incidence of rickets may be mentioned. According to official statistics in 1928, 87 per cent. of a group of 1635 five-year-old London school-children<sup>7</sup> were found after special examination to show evidence of "some degree of rickets"; yet in the great majority of cases their nutrition would have been returned as "normal" by the ordinary school medical examination.

Finally the experiments of Corry Mann may be alluded to. Carefully controlled experimental observations by

this worker<sup>8</sup> and by many others subsequently<sup>9</sup> have shown conclusively that for optimum development and health a school child needs not less than one pint of milk per day. Yet, although large sections of the population are unable to receive their daily pint, examination by the school medical service—which under existing conditions must frequently be somewhat cursory—is generally incapable of revealing such degrees of sub-optimum nutrition.

It is considerations such as the foregoing which indeed form the justification for basing estimates of malnutrition (or undernutrition) not so much on existing public health returns as on a knowledge of the amount of money actually available for food for given groups of the population. When the amount of money available is less than that which expert opinion<sup>10</sup> considers to be the minimum necessary for the maintenance of health, then a presumption must be raised that some degree of undernutrition is present. Orr<sup>11</sup> calculated in 1934 that no less than 10,000,000 individuals in this country were unable to afford even the bare minimum figure (at the present time perhaps 20,000,000, representing 40 per cent. of the population, are considered to have diets below the optimum<sup>11a</sup>).

To sum up the foregoing arguments, it may be said that three principal objections can be raised to attempts to assess undernutrition by methods based solely on physique, on physical performance, or on superficial clinical appearance. These objections are: (1) the absence of standards of reference, (2) that such standards as do exist may be debased standards, and (3) that the worst and more obvious of the effects of undernutrition may be delayed.

(1) *Absence of standards.*—The difficulties due to absence of standards are at once apparent from statistics such as the following: In comparable areas in Northumberland (as Dr. J. C. Spence has pointed out<sup>12</sup>) the official returns for malnutrition may vary from 0.5 per cent. to 7.5 per cent. ! At Bootle the malnutrition-rate is given as 12 times that of Liverpool—of which it is a suburb. Or, again a prosperous borough like Twickenham owns to a malnutrition-rate six times that of Wigan.

(2) As to the use of *debased standards*, it is sufficient to say that large numbers of returns are based on *past averages* instead of possible optimal figures, and it is often overlooked that there has been a steady improvement in height and weight values for elementary school-children in many parts of the country during the past decade or two; while in controlled experiments in which children have been allowed more generous dietaries their weights and heights have shown considerable advances over the

old average figures, which are still too often taken as "normal" values. No doubt the ideal standards for weights and heights under conditions of optimum nutrition have still to be determined.

(3) As to the difficulty of recognising the milder or earlier stages of malnutrition enough has already been said to show that disorders such as nutritional anæmia, mild or early rickets, and sub-scurvy, may be the cause of definite ill-health and lead to still more serious defects in later life and may yet escape notice unless special methods are used for their detection.

A consideration of these facts leads me to suggest that the time is ripe to draw up a schedule of the tests which are now available for the determination of specific nutritional deficiencies. It is greatly to be hoped that a series of surveys employing such methods of test should be undertaken (on random specimens of the population) in different areas, so that a conspectus may be obtained of the incidence of definite defects of nutrition throughout the country.

### Tests for Specific Deficiencies

#### VITAMIN A

(a) *Photometer test* (Jeans and Zentmire).—The most sensitive method so far proposed for the detection of vitamin-A subnutrition is based on sensitivity to light following partial dark adaptation. The principle of the technique depends on the well-known fact that visual purple is a compound of vitamin A, and that in the absence of an optimum dietary allowance of the vitamin the rate of regeneration of the visual purple is subnormal. As a check on the accuracy of the method, those subjects showing low values should be given an adequate source of vitamin A for a week or two, and if such treatment is found to be duly followed by a return to a normal visual value, it may be reasonably held to confirm the conclusion that vitamin-A deficiency was the cause of the defect.

Using this method Jeans and Zentmire<sup>13</sup> found that in a group of 213 children from Iowa City, U.S.A., whom they examined, no less than 45 had subnormal dark adaptation. Of the latter, a group of 21 were treated as controls with cod-liver oil, and were then found to return to normal in an average period of 12 days. The subjects chosen for investigation were, it is true, a group of physically afflicted children from the lower economic classes, but it is significant that as many as 21 per cent. were found to have some degree of vitamin-A deficiency.

(b) *Post-mortem determinations of liver reserves.*—Some indication of the variations in the vitamin-A reserves in different sections of the population may be obtained from post-mortem analyses of the liver (carried out by means of a colorimetric test, by the  $SbCl_3$  method). The vitamin-A reserves of the body are known to be stored almost entirely in the liver, and the amount so stored depends on that provided in the diet. For the sake of more accurate comparison, accident or surgical cases are best taken, since in medical cases the possible provision of a diet rich in vitamin A since admission to hospital may sometimes give a figure deceptively higher than that truly representative of the previous home conditions. Absolute standards of "normality" for the liver reserves are not yet known, so that results must be given a general qualitative significance rather than a strict quantitative interpretation. The most comprehensive results so far published are due to Moore,<sup>14</sup> and he gives the provisional finding

that about 16 per cent. of cases show "subnormal" vitamin-A reserves. For purposes of calculation it may be borne in mind that the minimum daily dose of vitamin A needed by a man, woman, or child is thought<sup>15</sup> to be in the region of 1000 "Sherman-Munsell rat units" (= about 1400 international units) per day.

#### VITAMIN B<sub>1</sub>\*

*Urinary excretion test.*—A method has just been described (Harris and Leong)<sup>16</sup> by which the amount of vitamin B<sub>1</sub> excreted in the urine may be used as an index of the dietary intake. Large-scale surveys have still to be undertaken, but as a provisional guide it may be held that subjects excreting less than 12 I.U. (international units) per day (for a ten-stone man) and failing to show a response to a single test dose of (say) 500 I.U. have been receiving a diet unduly low in vitamin B<sub>1</sub>. The significance of a suboptimal intake of vitamin B<sub>1</sub> in nutrition may be seen from the results of various workers who have shown that the weight and height gains of children were considerably improved beyond those of the controls when extra vitamin B<sub>1</sub> (or B) was added to the diet (mainly in the form of cereal preparations).<sup>17</sup>

#### VITAMIN C

(a) *The urinary excretion test* depends on the fact that the amount of vitamin C excreted daily in human urine and the response to a test dose depend on the past intake<sup>18 20</sup>: the measurements are made by a simple chemical titration, depending on reduction of the redox dye, 2 : 6-dichlorophenolindophenol under specified conditions. A considerable amount of quantitative work has already been done. It has been shown<sup>20</sup> that if less than a certain amount of specific reducing substance (expressed as ascorbic acid) is excreted daily (viz., 1.0 to 1.5 mg. per stone of body-weight) and if there is no response to a given test dose (viz., 70 mg. per stone of body-weight), a presumption must be raised that the diet of the subject has contained less than the reputed minimal-optimum dose of vitamin C<sup>21</sup> (e.g., 25 mg. per day for an adult).† A survey of subjects of the voluntary hospital class, recently concluded,<sup>22</sup> indicates that a suboptimal intake of vitamin C is indeed of common occurrence. It has similarly been pointed out that although current teaching recommends the consumption of orange juice daily by all bottle-fed babies, many do in fact receive too little—a conclusion confirmed by tests carried out on the urine.<sup>20</sup>

(b) *Capillary resistance test* (Göthlin).—An alternative method described by Göthlin<sup>23</sup> depends on the fact that with inadequate intake of vitamin C the capillary resistance becomes subnormal. This is apparently the earliest clinical symptom of sub-scurvy. As measured by Göthlin's method, a count

\* *Vitamin-B<sub>1</sub> complex.*—The significance of the various components of the vitamin-B<sub>1</sub> complex in human nutrition is not yet sufficiently well understood to warrant any detailed consideration here. The following points may be worthy of note however:—

*Lactoflavin* is excreted in the urine, and apparently in amounts depending on the dietary consumption, and it may be estimated readily by a fluoroscope test; but until more is known of the physiological rôle of lactoflavin and the effects of its deficiency, such tests are outside the scope of our present discussion.

*Vitamin B<sub>2</sub>*, the so-called rat-pellagra factor,<sup>14</sup> is also of unknown significance for human nutrition, and no methods of test for its deficiency in man are known.

*The pellagra-preventing (PP) factor*, although it has not yet been chemically identified, is of importance in many regions of the globe—e.g., over 7000 deaths per annum from pellagra occurred in the U.S.A. in 1928–30, according to official returns. Unfortunately no tests seem yet available for subclinical degrees of deficiency.

† This is approximately the amount said to be needed to restore to normal a diminished capillary resistance due to hypovitaminosis C: see below.

is made of the number of petechiæ which appear in a given area on the surface of the arm when a stated pressure is applied by means of a tourniquet. The objection which may be raised, that a diminished capillary resistance is not pathognomonic for scurvy but is seen in other conditions also, is largely met by a procedure described by Göthlin, according to which whenever a low value is found a source of vitamin C may be administered and a return to a normal value in the course of a week or two confirms the diagnosis. By this method Göthlin<sup>24</sup> found that in Norrland (in Northern Scandinavia) one child out of every five gave evidence of hypovitaminosis C.

#### VITAMIN D

(a) *Blood phosphatase test for active rickets.*—Probably the most sensitive test for detecting active or current rickets is based on a measurement of the amount of phosphatase in the blood, as described by Smith.<sup>25</sup> With the start of the rachitic process the phosphatase content of the blood rises above normal, and promptly sinks again once the curative action has begun. The laboratory estimation is fairly straightforward, and should be made the subject of surveys on a larger scale.

(b) *Examination for past rickets.*—As it is important to know not only whether the rachitic process is active at the moment when the test is carried out but also whether there is a history of rickets, an examination should be included for the stigmata of past rickets. The methods used (see for example the London inquiry of 1928<sup>7</sup>) are simple and well known; X ray investigation should be combined with examination for enlarged epiphyses and characteristic bony deformities (the Newman Committee of 1931 accepted the following<sup>26</sup> as "rachitic signs": parietal bossing, frontal bossing, radial epiphyses, spinal curvature, knock knees, bow legs, bowing of tibia, beaded ribs, changes in chest wall).

#### IRON (NUTRITIONAL ANEMIA)

The striking results of Mackay and others<sup>27</sup> on the high incidence of nutritional anaemia, and of the damage which it causes to health, have already been alluded to. When the laboratory method for its detection is so relatively simple, there is every reason why it should be included in nutritional surveys of the kind we have in mind.

#### OTHER ESSENTIALS

The above list, while making no claim to completeness, probably does summarise the tests which are most easily carried out.

Evidence of a deficient intake of other important dietary constituents, such as protein, or calcium, or phosphate is more readily determined by a direct study of the budget and of the food actually consumed by the members of the family—rather than by the necessarily complex procedure of estimation of "retention" in "balance" experiments. The latter kind of inquiry has, it is true, given invaluable information in a few well-chosen surveys which have been carried out, mainly in the hands of Sherman and his co-workers in America. Such tests are, however, generally beyond the scope of ordinary routine inquiries. An exception might, perhaps, sometimes be made for blood analysis for calcium and inorganic phosphate, a low phosphate (or low Ca × P product) being nearly always indicative of a rachitic process. Similarly, hypocalcaemia, giving rise to spasmophilia, may be detected by diminished resistance, on test, to electrical stimulus.

#### Summary

Limitations in the method of assessing under-nutrition by means of observations based on the

superficial clinical appearance, on physique, or on physical performance are: (1) the absence of standards of reference, (2) that such standards as are in use may be debased, (3) that the more obvious ill-effects of under-nutrition may be delayed, and (4) that such methods may fail to indicate the specific nature of the deficiencies responsible. The following methods, inter alia, are now available for the determination of specific deficiencies.

- (1) *Vitamin A.*—(a) Photometer test for dark adaptation (visual-purple formation). (b) Post-mortem estimates of vitamin-A reserves in liver.
- (2) *Vitamin B<sub>1</sub>.*—Urinary excretion test.
- (3) *Vitamin C.*—(a) Urinary excretion test. (b) Test for diminished capillary resistance.
- (4) *Vitamin D.*—(a) Phosphatase test for active rickets. (b) X ray and clinical examination (bony deformities) for past rickets.
- (5) *Iron* (nutritional anaemia).—Hæmoglobin estimations.

Surveys are required based on the collection of such data.

CENTRAL JUBILEE FUND.—A grant of 50,000 rupees (about £3500) from this fund is to be spent by the Ludhiana Women's Christian Medical College, a hospital in the Punjab, on radium. The college, which was founded by Dame Edith Brown, M.D., 42 years ago, was the first medical school for training Indian women. It now has in training 150 medical students, 50 nurses, 20 compounders, and 80 dais. It is supported partly by Government grants and partly by British and American missionary organisations.

## MEDICINE AND THE LAW

### Claim for Negligence against Surgeon and County Council

Mr. Justice Finlay has an important judgment to deliver in the present legal sittings in the action brought by Mrs. Dryden against Dr. John Stewart and the Surrey County Council. The plaintiff claims damages for alleged negligent treatment during and after an operation performed at the Epsom Hospital in November, 1934. She alleges that surgical packing was inserted after the operation and that no proper precaution was taken for its removal. It is her case that the packing must have been inserted under an anæsthetic when the doctor was in charge; if inserted by a nurse, it could not have been done without the doctor's knowledge. Against the defendant county council she complains that her symptoms were not properly reported to the doctors in charge: she says she was discharged from the hospital as recovered when she was really a very sick woman, and that in consequence she developed pyelitis and cystitis and suffered pain and that this trouble was likely to recur at any future pregnancy. The case was opened at the Surrey assizes and adjourned to the High Court in London. The defence is a denial of the alleged negligence. Dr. Stewart says he is certain he left no swab at the time of the operation; if any packing or plugging had been used, the fact would have been noted on the patient's bed card. The county council says it is not called upon to explain the presence of the packing: it denies that the hospital nurses were negligent, and it contends that the nurses were not, when taking part in the operation, the servants of the hospital; the hospital and the nurses did not stand in the relative position of master and servant; the hospital could not tell the nurses how to do their duties. On the other hand, the plaintiff's counsel has asserted that this legal rule, whereby a hospital is not liable for the negligence of its skilled staff, is based on the view that the services of the hospital are gratuitous. He says it could not be argued that a nursing-home (where patients are paid for) is not responsible for the negligence of its staff. As 30s. per week were paid for Mrs. Dryden at the Epsom Hospital, it is contended by her counsel that she is in the same position as if she had paid 20 guineas a week in a nursing-home. It will thus be seen that the judgment which Mr. Justice Finlay is to deliver as soon as possible after the Easter vacation promises to be full of interest to the medical profession and to hospitals.

### Poor Prisoners and Their Witnesses

In commenting on the proceedings against Mrs. Harding (*THE LANCET*, April 11th, p. 860) where fresh medical evidence was admitted in the Court of Criminal Appeal with the result that her conviction was quashed, we suggested that it was strange that the evidence was not available at the trial. When this fresh evidence was tendered, her counsel apparently explained its previous absence by stating that she was defended under the Poor Prisoners' Defence Act. A correspondent has written to point out that, if Mrs. Harding's counsel was briefed from the dock, he deserves all possible credit for having ultimately obtained the necessary evidence and for having successfully submitted it to the appellate tribunal. Nobody will wish to belittle the advocate's unselfish work or the intervention of the medical

witness whose official position happily gave him an opportunity to serve the cause of justice. Exactly what happened in the appointment of a barrister to defend Mrs. Harding is not quite clear. A "dock defence" is the name usually given to the direct instruction of counsel by an accused person. There is an ancient forensic convention that anybody who is tried on a criminal charge can produce a guinea and claim to be defended by any barrister who is present in court and is not engaged for the prosecution. This is one of the exceptional cases where a lay client can instruct a barrister directly without the intervention of a solicitor. It naturally follows that there is scant opportunity for obtaining witnesses, since the barrister is acting on the spur of the moment and since it is not the province of a barrister but of a solicitor to seek out and mobilise prospective witnesses. Another method of extempore defence is illustrated when the judge asks some barrister in court to undertake the defence of an undefended prisoner. This the judge will do if he sees a possible line of defence; it is a chance for a young barrister to show his paces, and his services are given gratuitously. These two methods existed long before the Poor Prisoners' Defence Act was passed. The statute has made a twofold difference: in the first place both solicitor and counsel can be assigned and will receive a prescribed fee; secondly, since the solicitor is assigned in advance of the trial, there should be no difficulty in securing the attendance of necessary witnesses.

### Coroner on Medical Errors

Dr. R. L. Guthrie, the East London coroner, recently observed that, if every doctor was to blame for every mistake, medical practice would be impossible. He was completing an adjourned inquest on a patient who had undergone an operation for appendicitis but whose appendix was found to be free from disease. It was clear that the surgeon had examined the patient with all proper care; a medical witness said he considered the operation necessary "even in the light of after events." The surgeon was exonerated from blame and a verdict of "death by misadventure" was recorded. Dr. Guthrie's observation is a useful reminder that medical science makes no pretence to the exactness of the multiplication table and that there is certainly no liability in criminal negligence for a mistaken diagnosis, made after a reasonably careful examination of the conditions, if the resultant treatment should unhappily end fatally.

## UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

### A NEW SURGEON-GENERAL

Dr. H. S. Cumming having recently resigned as surgeon-general of the U.S. Public Health Service on grounds of ill-health, after a long and most distinguished career, President Roosevelt named Dr. Thomas Parran, Jr., to succeed him. A few days later this appointment was ratified by the senate and Dr. Parran was getting ready to leave Albany for Washington. He will be the youngest surgeon-general in the history of the service. He was born at St. Leonard, Maryland, in 1892 in a house built of English bricks; one of his ancestors brought these bricks across the Atlantic as ballast for a tobacco ship. After a successful career in the public health service Dr. Parran was appointed commissioner of health for New York State. That was in 1930 when

Franklin D. Roosevelt was governor. Last autumn in Milwaukee Dr. Parran became president-elect of the American Public Health Association. Dr. Parran holds somewhat advanced views on public health, and especially on what we call "socialised medicine." Members of the medical profession will watch with some anxiety to see what influence these views will have in shaping the policies of the public health service. Science Service news agency announces that Dr. Parran's programme has been summarised by himself as follows:—

1. To finish the job of wiping out tuberculosis.
2. To wipe out . . . syphilis, the end-results of which "crowd our jails, our poor-houses and our insane asylums."
3. To make available to people everywhere facilities for the proper diagnosis and treatment of cancer. . . .
4. To reduce the "disgracefully high" death-rates of mothers in childbirth and babies in the first month of their lives.
5. To correct the conditions resulting from improper diet.
6. To restore crippled children to lives of usefulness.

Dr. Parran visited Sweden last summer and came back deeply impressed with the success of that country's campaign to control syphilis. When he was refused permission to use the word syphilis even in the most general connotation in a radio address he resigned from the committee for education by radio.

## PARIS

(FROM OUR OWN CORRESPONDENT)

### SOME VENEREAL DISEASE STATISTICS

WHEN due allowance is made for the wide gulf between statistics and veracity, it is possible to glean interesting and sometimes instructive information from them. The Union des Caisses d'Assurances Sociales of Paris has recently issued a study of the incidence of, and campaign against, venereal disease in France. It appears that as many as 20 per cent. of men suffering from syphilis are aged 30-40, and only 5 per cent. aged 50-55; in other words, syphilis is pre-eminently a disease of the best working age. The same authority estimates that 10 per cent. of all cases of invalidism can be traced to syphilis. Still more arresting are the figures quoted by Dr. Cavaillon and Dr. Dufour in an appendix to this study. They calculate that, every year in France, syphilis causes 20,000 deaths between the sixth month of intra-uterine life and the third month of infancy. It prevents the birth of 40,000 infants every year, causes 80,000 deaths, and costs 140,000 human lives, even when no account is taken of the degenerate, the blind, the deaf-mutes, the paralytic, the ataxic, &c. What is perhaps the most startling statement of all is that 40 per cent. of the diseases for which treatment is given in hospital are venereal. Insanity costs France more than 200 million francs a year, and a quarter is attributed to syphilis. In 1916 a veritable epidemic of syphilis was a source of grave concern to the French public health authorities. Since then, the defensive reaction has been so effective that, at the beginning of 1936, the country was equipped with 1821 venereal disease services, not including the services attached to hospitals and certain dispensaries. Thanks to the activities of these centres, neurosyphilis has been reduced to such an extent that tabes is ten times less common

than it was before the war. It is a curious and not altogether satisfactory observation that the care of venereal disease patients is shared by well equipped, more or less public, services and unscrupulous quacks. The general practitioner is out of the picture.

### A FRENCH MEDICAL DEFENCE UNION

The Ligue Médicale de Défense Professionnelle, commonly and affectionately known as "Sou Médical," is very much of a going concern. It is affiliated to the weekly journal, *Concours Médical*, in the sense that you wash one hand with the other. Between 1926 and 1933 the average number of new members per year was 394; in 1935 they numbered 739. At the end of 1925 there were 4500 members, and at the present time there are 7273. A list of the cases dealt with shows that the recovery of medical fees is the sphere in which the aid of his defence union is most often invoked, and there is an increasing proportion arising out of accidents—road and occupational. Differences of opinion between doctors and tax collectors also seem to be common. The material resources of Sou Médical amount to more than two million francs; this backing helps it to insure its members, who pay 100 francs a year, for 100,000 francs against the risk of "la responsabilité civile," a term which even courageous linguists shirk translating. When a member pays 150 francs a year, he not only becomes a reader of, or at any rate a subscriber to, *Concours Médical*, but he has his aforementioned risk covered to the tune of 500,000 francs. With its six lawyers and experts in other fields, Sou Médical is in a position to render much useful service at a very moderate charge.

LOUIS HENRI VAQUEZ

The death is announced of Prof. Vaquez on April 15th at his home in Paris. Born in 1860, he had a distinguished medical career and he enjoyed an international reputation as a specialist in diseases of the heart. To many his name will be familiar in connexion with the instruments he devised for measuring the blood pressure. He was a professor of the faculty of medicine of Paris, a member of the Academy of Medicine, and an officer of the Legion of Honour.

## IRELAND

(FROM OUR OWN CORRESPONDENT)

### COMPULSORY RETIREMENT OF OFFICERS OF LOCAL AUTHORITIES

At the last meeting of the joint committee of the Grangegorman and Portrane mental hospitals, a resolution was passed which stated: "That, in compliance with the instructions of the Minister for Local Government and Public Health as set forth therein, all established officers aged 65 years and upwards now eligible for full or partial superannuation under the 1890 or 1909 Superannuation Acts be requested to submit their resignations and applications for superannuation at the next monthly meeting." The action of the committee is an example of the confusion into which local authorities throughout the country have been led by the lack of clarity in the circular issued some weeks ago by the Minister for Local Government and Public Health. Local authorities still persist in regarding the circular as mandatory despite the Minister's repudiation of such an interpretation. On March 12th in the Dáil he

stated that no Order had been made, and on March 24th he repeated this statement explicitly: "The circular letter is by way of recommendation to local authorities; it is not an order." He further stated that the local authorities had powers enabling them to take the action recommended in the circular, but he was silent when questioned for the statutory reference to such powers. The possession of such powers is widely questioned, and it has been stated in the daily press that the Local Government Officials' Association—a body representative of the officers of local authorities—has obtained opinion of senior counsel that no such power resides in the local authorities. The council of the Irish Free State Medical Union has advised its members who might be adversely affected if the recommendations of the circular were carried out to take no step toward resigning at present.

#### MR. HENRY S. MEADE

The French Government has conferred on Mr. Henry S. Meade the rank of Chevalier de la Légion d'Honneur. Mr. Meade, who is one of the surgeons to St. Vincent's Hospital, Dublin, worked as a surgeon for a considerable time in French hospitals during the late war.

## PANEL AND CONTRACT PRACTICE

### Test Prescriptions

A PRACTITIONER in the Home Counties was asked to write a test prescription and did so, under protest, in such a way as to make it clear to any chemist to whom it might be presented that it was a test prescription. Approached in turn by the insurance and the panel committee he relented to the extent of saying he would be prepared to issue an amended prescription, but he was adamant in his intention to inform the local chemists that he was issuing it. His attitude is accordingly being investigated by the medical service subcommittee. During the discussion a medical member of the committee imputed to the sponsor of the Act the statement that the dispensing of medicines by chemists was designed to secure that doctors should not give their patients "bad drugs," but it now appeared that an elaborate intelligence system was necessary to ensure this. If there had to be a system of tests it should, he thought, be an efficient one. He seems to have been unaware that the schemes for testing drugs and appliances supplied to insured persons are designed simply to check the accuracy with which they are dispensed. Under their terms of service the drugs and appliances which chemists supply must be of a grade or quality not lower than that specified in the Drug Tariff, which is almost invariably that of the B.P. or its codex. If not included in it they must be of a grade or quality not lower than that ordinarily used for medical purposes. Inspectors under the Food and Drugs Acts see that drugs are of a proper degree of purity. In the early days of the testing scheme, before the issue of test prescriptions was made part of the practitioner's terms of service, the protestant would prescribe for Mr. B. Ware, Mr. O. B. Careful, or Mr. A. Test.

### Secrecy of Records

There has been some concern about the possible leakage of information on forms of medical record. The instructions to insurance committees lay it down that the obligation laid on them to maintain strict secrecy as to the information in their possession extends generally to all information, of any kind whatever (including names and addresses), about all classes of insured persons and their dependants,

### FOTHERGILL TESTIMONIAL FUND

THE following is the fifth list of subscribers to the testimonial to Dr. E. Rowland Fothergill received in response to the letter published in the *British Medical Journal* and *The Lancet* of Jan. 18th:—

Amount previously acknowledged, £1361 12s.  
R. L. Newell (Manchester), £2 2s.; Carnarvonshire Panel Committee, £5 5s.; E. R. Sweeney (London), 10s. 6d.; J. P. Davie (Chesterfield) and H. Downer (Hove), each £1 1s.; Bedfordshire Local Medical and Panel Committee, £21; Carmarthenshire Panel Committee, £5 5s.; Portsmouth Panel Committee, £13 8s.; Northampton Panel Committee, £2 2s.; Glamorgan Panel Committee, £10 10s.; C. J. Marsh (Yeovil) and A. T. Jones (Mountain Ash), each £1 1s.; J. Macfadyen (Newcastle-on-Tyne), £1; F. A. L'E. Burges (Birmingham), £2 2s.; Sir Thomas Dunhill (London), £3 3s.; F. H. Alexander (Littlehampton), H. Child (Brighton), —, Marshall, F. Hinds (Worthing), N. E. Chadwick (Hove), D. D. Macintosh (Worthing), W. N. Maple (Hove), Nora Crow (Brighton), A. Barnes, Sir Hubert Bond (Brighton), A. E. Cawston (Lewes), J. V. Banner (Brighton), W. A. Wood (Brighton), and Roderick Clapham (Hove), £27 9s. 6d.; W. P. S. Branson (Frimley Green), £2 2s.; B. R. Rygate (London), 10s.; C. F. T. Scott and W. Paterson (Willesden), each £1 1s.; Adam Fulton (Harrogate), £2 10s. Total £1466 17s.

It has been decided that the fund will be closed at the end of May and it is hoped, therefore, that any intending subscribers will forward before that date their contribution to the treasurer, Fothergill Testimonial Fund, British Medical Association, B.M.A. House, Tavistock-square, London, W.C.1.

which may come into the possession of the committee, its members, and officials in their official capacity. Even when application is made by the police for information as to the addresses of insured persons, the foregoing instructions are sufficiently explicit to warrant the refusal of information. In cases where the entries on a record card are likely to be of assistance to the investigation of a question by the medical service subcommittee, it is the practice to secure the consent of the insured person to the production of the medical record before it is even examined by the subcommittee.

### Grubby Envelopes

An insurance doctor had employed a surgery attendant who for many years had been in the habit of taking the medical records from the file as patients arrived so that each patient on passing into the consulting-room could himself hand the F.M.R. to the doctor or his assistant. After surgery hours the attendant would restore the records to the cabinet, but naturally over a period of years some of the envelopes became dirty. Recently the doctor appointed a new surgery attendant who developed pulmonary tuberculosis. The doctor pointed out to the insurance committee that it was difficult effectively to disinfect and clean the envelope records and asked for duplicate envelope records to which he might transfer the notes. The committee consulted the Department, who took the view that, in the special circumstances, if in the case of such records as the doctor considered should be renewed he would enter on the back of a new envelope a brief summary of the essential facts of the medical history, as indicated by the clinical notes on the old envelope, the latter might then be destroyed. No notes other than this summary should be made on the fresh envelope; particulars of further illnesses, for instance, should be recorded on continuation cards. Medical records have now been in existence since January, 1921, and the condition of some of them, especially where handled by the insured persons themselves, is certainly not hygienic. Other practitioners will be considering the desirability of substituting a clean new record where the condition of the existing record is unsatisfactory.

## CORRESPONDENCE

## PLACENTAL EXTRACT IN MEASLES

To the Editor of THE LANCET

SIR,—Several references have appeared in our medical journals, following observations reported in the American literature by McKhann and Chu and others, to the use of a new reagent for passive immunisation in measles. This reagent, known as placental extract or immune globulin (measles), has awakened wide interest, and I have received many inquiries from practitioners and medical officers of health as to its value in prevention and attenuation in measles. Through the foresight and courtesy of my laboratory and administrative colleagues in the London County Council, and Dr. Petrie of the Lister Institute, I have been able to try three samples of this reagent. As will be seen from the following the results have been favourable, and in view of the importance of the subject I have thought it desirable to give some details of these preliminary experiments.

The first step was to demonstrate if possible the fact that placental extract does in fact contain measles antibody, and an attempt was made to produce the immunity reaction of Ravina and Debré. Convalescent measles serum and placental extract were accordingly injected at separate sites intracutaneously in 0.2 c.cm. amounts into the skin of a patient in the early prodromal stage of measles. On the rash appearing three days later it was inhibited over the area of skin infiltrated by the two reagents. The convalescent serum area was however about twice as large as that produced by the placental extract, and the inhibition of the rash was complete, whereas with the placental extract, although the area of inhibition was quite distinct it was not quite complete in that there were faint traces of rash.

Having thus proved that the extract contained measles antibody, comparative passive immunisation experiments were carried out when opportunity arose as a result of measles cross-infection in various wards. In each ward outbreak the exposed susceptibles were divided into two groups of approximately equal number and similar age-distribution. One group received 5 c.cm. convalescent measles serum and the other varying doses of placental extract. The day of exposure varied from one to five days, but in only one outbreak was complete protection obtained with both reagents, whilst in another complete protection was obtained in the convalescent serum group but not with placental extract. Otherwise the occurrence of mild or modified cases was fairly equally distributed according to the numbers in the groups and the type of reagent. In all 69 children received injections, 35 receiving convalescent measles serum and 34 placental extract. In the convalescent serum group 7 contracted modified measles, and in the placental extract group 7 contracted modified measles and 3 mild measles. All cases were uncomplicated with one exception in the placental extract group, a child of two years suffering from severe whooping-cough developing double otitis media ten days after the onset of mild measles. Reactions after injection of placental extract consisted in a flicker of temperature to 99° or 100° F. the day after injection in most cases, whilst one case showed an erythematous rash a week later. The dosage employed with two of the extracts was 10 c.cm. and 3 c.cm. respectively, the dosage recommended by the laboratory of origin, whilst the third extract was employed in double the dose—viz., 4 c.cm. My

results are insufficiently numerous to lend themselves to analysis from this point of view, and in any case the dosage must vary with the degree to which the laboratory worker feels justified in concentrating his product.

From these results it would appear that in placental extract we have a reagent available for passive immunisation in measles, less potent perhaps than convalescent measles serum, but at least equal to adult serum. The importance of this can hardly be over-estimated in view of the difficulty in maintaining an adequate supply of the latter reagents. Obviously the routine commercial distribution of placental extract through the ordinary channels would present no difficulty.

I am, Sir, yours faithfully,

ALEX. JOE.

North Western Hospital, Hampstead, N.W., April 20th.

## HYPERVITAMINOSIS D

To the Editor of THE LANCET

SIR,—Dr. Thatcher's paper and Prof. Tanner Hewlett's letter, in your issues of Jan. 4th and 11th, leave unanswered the question: "What determines the toxicity of cod-liver oil? Does this depend on its vitamin-D content?"

The available evidence, both experimental and clinical, is conflicting. Thus A. F. Hess and Lewis<sup>1</sup> in 1928 found that patients receiving 2.5 mg. of irradiated ergosterol daily lost weight, developed slight fever, and had hypercalcaemia, hyperphosphatemia, and albuminuria. Bamberger and Spranger<sup>2</sup> in the same year observed vomiting, loss of weight, and albuminuria in 10 of 11 tuberculous children receiving varying doses of irradiated ergosterol up to 30 mg. daily (from 0.4–2.5 mg. per kg. of body-weight). Gyorgy<sup>2</sup> (1929) reports the same effects also, in children with tuberculosis, from daily doses of from 3–10 mg. Two deaths clearly attributable to irradiated ergosterol have been reported<sup>2</sup>: in Putscher's (1929) case an infant given six drops of Vigantol daily died at the age of five months; while Thatcher's (1931) patient was a boy aged eighteen months, for whom a quantity of irradiated ergosterol "equal to about twice the recommended curative dose" had been prescribed. Gough<sup>2</sup> (1933) produced lesions in the kidneys of rats by moderate doses of vitamin D combined with large doses of acid and alkaline orthophosphates. On the other hand, J. H. Hess<sup>3</sup> gave infants up to 52 times the prophylactic antirachitic dose for long periods and 250 times that dose for short periods without producing hypercalcaemia or any of the clinical signs of overdosage reported by other writers. Furthermore, I have notes of a case of a three-year-old male child who has been taking vigantol, five drops three times daily, and continuously, since he was two years old for treatment for one of the radiological heresies "hilum tuberculosis." His health, weight, appetite, and urine have all been normal throughout.

Healthy adults taking large quantities of cod-liver oil occasionally develop tachycardia and precordial discomfort, even when there is no question of gastric disturbance to account for this (E. Mellanby, 1924).<sup>4</sup> Agduhr<sup>4</sup> (1926–29) found that cod-liver

<sup>1</sup> Hess, A. F., and Lewis, J. M.: *Jour. Amer. Med. Assoc.*, 928, xci., 783.

<sup>2</sup> Quoted by Hadfield and Garrod: *Recent Advances in Pathology*, London, 2nd ed., p. 145.

<sup>3</sup> Hess, J. H., et al.: *Jour. Amer. Med. Assoc.*, 1930, xcv., 316.

<sup>4</sup> *Vitamins: A Survey of Present Knowledge*. Med. Research Council, Spec. Rep. Ser. No. 167, London, 1932.

oil, given continuously to animals, may produce toxic effects on the heart and the development of pigment and/or fatty degeneration of the heart-muscle, transformation of the muscle-cells into connective tissue, and calcareous incrustations. Norris and Church<sup>4</sup> (1930) have shown that small doses of isoamylamine, as found in cod-liver oil, and also choline, given continuously, may produce paralysis, convulsions, and lack of growth; they suggest that these bases may be the toxic agents in cod-liver oil. As evidence that cod-liver oil in large doses is not necessarily harmful I may mention that a man I know, a police officer 25 years old, who is exposed to the sun of the tropics most of the day, has been in the habit, since 1930, of taking two coffee-cups full of pure cod-liver oil three times daily, because he is thinly built. He has so far remained in perfect health and shows no sign of any toxic effect. It is a pity that, in spite of recent studies, we are still unable to establish for certain the factor or factors which prevent cod-liver oil from being, in Prof. Hewlett's words, "the entirely innocuous substance it is generally supposed to be."

I am, Sir, yours faithfully,

HOSNY AYAD,

P.M.O. Government Hospital, Shanshour, Egypt.  
March 26th.

#### "HYPERGLYCÆMIC COMA"

To the Editor of THE LANCET

SIR,—Perusal of p. 894 of your last issue has stimulated me at length to give voice to a protest against the term "hyperglycæmic coma." This term is inaccurate, coma not being produced by hyperglycæmia. The term is educationally misleading. As an examiner in medicine and in therapeutics, and to nurses, I have been struck by the large number of candidates who have been misled. The individual who first introduced the phrase has well merited a long term of penal servitude for the intellectual crime he has committed. Teachers who persist in using it, and writers who perpetrate it, are accessories after the fact. Why not talk of diabetic coma in contra-distinction to hypoglycæmic or insulin coma?—I am, Sir, yours faithfully,

London, W., April 20th.

GEOFFREY BOURNE.

#### MENTAL HYGIENE IN MENTAL HOSPITALS

To the Editor of THE LANCET

SIR,—Might I suggest, since apparently the pages of THE LANCET are now thrown open to such major issues, that as a further elementary axiom "Four Asylum Psychiatrists" should be compelled to learn that the word "asylum" in this country is by law non-existent, and that such an "hygienic" measure as they propose, and seem to need, can hardly prove effective during such a short compulsory evacuation.

I am, Sir, yours faithfully,

T. J. HENNELLY.

Cardiff City Mental Hospital, April 20th.

#### SEX AND CULTURE

To the Editor of THE LANCET

SIR,—My attention has been drawn to a leading article (in your issue of Feb. 22nd) on Sex and Culture by a pious adaptation in one of our American health periodicals. We puritans love to upholster our prejudices with scientific trimmings and the rather broad generalisations in your editorial give us ample opportunity. Let us suppose that Dr. Unwin has established a correlation between temple building and sexual restraint, and that his fellow anthropologists will agree to his thesis. Let us assume that temple building is evidence of cultural progress

amongst uncivilised people, though why it should be so regarded it is hard for a layman to imagine and your article does not explain. But suppose it is! Surely nobody wants us to believe that temple building and post-funeral attentions to the dead are evidence of culture in a *civilised* community? That would make the Quakers the least cultured of Christian sects and far less cultured than the Hindus. And see in the Old Testament the story of the Jews. Compare their sexual restraint in the days when they worshipped the Arc and built the Temple with their sexual morality when they discovered that "God dwelleth not in temples made with hands." Perhaps Dr. Unwin who lives after all in a civilised community needs to revise his social philosophy all over again.—I am, Sir, yours faithfully,

Santa Fé, N.M., April 4th.

J. ROSSLYN EARP.

## THE SERVICES

### ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. M. Brown to *Frobisher*; and R. W. Nesbitt to *President* for course.

Surg. Lt.-Comdr. F. B. Quinn to rank of Surg. Comdr.

Surg. Lt.-Comdr. T. W. Froggatt to *Pembroke* for R.N. Hospital, Chatham.

Surg. Lt.-Comdrs. (D.) C. J. Finnigan to *Pembroke* for R.M. Infirmary, Deal; R. M. Finlayson to *Rodney*; D. L. Simpson to *Boscawen* for R.N. Hospital, Portland; and H. J. Luck to *Pembroke* for R.N.B.

Surg. Lts. F. W. A. Fosbery to *Lupin*; M. A. Rugg-Gunn to *Repulse*; and W. W. Simkins to *Ganges*.

Surg. Lt. (D.) K. E. J. Fletcher to *Pembroke* for R.N. Infirmary, Deal.

Surg. Lts.—The following have been transferred to the permanent list: W. W. Simkins, W. J. F. Guild, F. W. Chippindale, M. G. Ross, W. A. Ryan, D. D. Steele-Perkins, G. H. C. Southwell-Sander, G. A. Lawson, and C. P. Collins.

### ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdr. A. R. Thomas to *Rodney* and to *Encounter*.

Surg. Lt. G. F. Jones to *Drake* for R.N.B.

Surg. Sub-Lt. R. T. Gaunt promoted to Surg. Lt.

Proby. Surg. Lt. R. R. Prewer to *Victory* for R.N. Hospital, Haslar.

### ARMY MEDICAL SERVICES

Col. N. Low, D.S.O., O.B.E., late R.A.M.C., having attained the age for retirement, is placed on ret. pay.

Lt.-Col. F. R. Coppinger, O.B.E., from R.A.M.C., to be Col.

### ROYAL ARMY MEDICAL CORPS

Lt.-Col. R. Gale, D.S.O., is placed on the half-pay list on account of ill-health.

Majs. C. D. M. Buckley, M.C., and J. C. A. Dowse, M.C., to be Lt.-Cols.

Short Service Commissions: Lt. A. MacLennan to be Capt.

### ARMY DENTAL CORPS

Capt. R. G. Law to be Maj. and retires receiving a gratuity. (Substituted for notification in the *Gazette* of Oct. 15th, 1935, *vide* THE LANCET, Oct. 26th, 1935.)

### TERRITORIAL ARMY

Capt. F. A. Belam (late R.A.M.C., Spec. Res.) to be Capt. Lt. H. Dickie to be Capt.

Lt.-Col. S. J. C. Holden, T.D., retires on account of ill-health and retains his rank, with permission to wear the prescribed uniform.

### ROYAL AIR FORCE

*Dental Branch*.—L. C. Bellsham-Revell is granted a non-permanent commission as Flying Officer and is seconded for duty at Guy's Hospital, London.

### INDIAN MEDICAL SERVICE

Capt. J. W. Richmond forfeits two years' service for purposes of promotion.

Lt.-Col. R. B. Lloyd retires.

## OBITUARY

**SAMUEL OSBORN, F.R.C.S. Eng., L.S.A.**

Mr. Samuel Osborn, who died at his house at Datchet, Buckinghamshire, on April 16th, having attained the great age of 88 the previous day, was well known for his distinguished work in the Red Cross service and on behalf of the aims and efforts of the St. John Ambulance Brigade. He was born at Brixton, the son of Mr. Samuel Osborn, F.R.C.S., and was educated at Epsom and at Wren's famous coaching establishment. He received his medical training at St. Thomas's Hospital, where he qualified

MR. OSBORN

(Photograph by Elliott &amp; Fry)

as M.R.C.S. in 1871 and held the resident appointments of house physician, house surgeon, and accoucheur. He became F.R.C.S. in 1876, and was for a time surgical registrar at St. Thomas's Hospital, and from 1878 onwards held the post of anaesthetist for five years, during which period he was a frequent contributor to the hospital reports, and wrote papers also in *The Lancet* and

the *British Medical Journal* on diseases of the testis. He was elected surgeon to the Hospital for Women in Soho-square, and at one time had a bent towards gynaecological practice, as was manifested in a small book entitled "Sympathetic Affections of the Breast, Bladder and Rectum, with Uterus and Appendages," but he did not long pursue this line of practice.

Osborn's associations with the Order of St. John of Jerusalem began over 40 years ago, and his St. John Ambulance lectures on First Aid to the Injured and on Nursing were fully recognised for their practical value at the time of their issue. They were couched in simple and practical terms, ran through seven editions, and were translated into many languages—Chinese, French, German, Greek, Japanese, Spanish, and Hindustani—making of their author a truly international character in ambulance work. His practical contributions to that work were many and great, and made in situations which were often attended with notable hardship, calling for courage as well as intimate knowledge. In the Greco-Turkish war in 1897 he was surgeon to the Red Cross and was appointed to the Royal Order of the Redeemer of Greece. In the South African war he was surgeon to Lord Methuen's column in the South African Field Force and, acting also as Red Cross surgeon, he was attached to more than one field hospital, was mentioned in dispatches, and was decorated with a medal and clasps in connexion with the campaign. At the cessation of hostilities he was appointed a Knight of Grace of the Order of St. John of Jerusalem, and later became permanent secretary of the International Red Cross Congress. In the Balkan

war of 1912 he was surgeon to the Turkish forces, and two years later at the outbreak of the European war he served as Red Cross surgeon in Belgium. On arrival at the seat of hostilities he found the Germans already in occupation, and his unit gave aid to both sides impartially. Later he was for two years resident surgeon to Lady Dundonald's Hospital in London. He was decorated by the King of the Belgians, and received also the Japanese Royal Red Cross decoration, having previously been an honorary member of the Japanese Red Cross Society.

The public value of Osborn's services was recognised by county and civic authorities, as well as by his own profession. He was a Lieutenant for the City of London and a J.P. for the county of Buckinghamshire. He was consulting surgeon to the Surgical Appliance Society and the Metropolitan Convalescent Institute, and was for many years surgeon to the Royal Naval Artillery Volunteers; for a period he sat upon the General Medical Council as a representative of the Society of Apothecaries, and he was Master of the Society in 1919-20. He was a traveller and a keen horticulturist. In all his public and professional work and as a frequent collaborator at *THE LANCET* Osborn showed himself a sympathetic colleague. He was able, kindly, and courteous, and many will feel his death as a personal loss.

**MAURICE HAMBLIN SMITH, M.A. Camb., M.D. Durh.**

Dr. Hamblin Smith, who died in Oxford on April 15th, was a great public servant, although the extent of his greatness was realised only by those who worked closely with him. As the son of his father he naturally took a Cambridge degree in mathematics, afterwards entering as a medical student at Guy's Hospital, from which he qualified in 1896. Following some experience of private practice at Silverdale, Staffs, he joined the prison medical service. After serving as deputy in several prisons he was in medical charge in succession of Stafford, Portland, and finally Birmingham, where he remained until his retirement. At Birmingham he adhered closely to the one principle in penology which James Devon stated to be worthy of attention: "to find out why a man does wrong and make it not worth his while." His book on the "Psychology of the Criminal" (1922) showed a rare combination of long experience in prison work, knowledge of modern psychology, and courage in the expression of opinion. It was his experience in Birmingham that a court of law, when it trusts its examiner, is ready to accept his statement either that he has discovered a repressed complex which he believes to be the cause of delinquency, or that he is of opinion that further analysis would be of advantage in throwing more light upon the case or in benefiting the patient by freeing him from the impulse to commit similar offences. The human beings unfortunate or unhappy enough to become criminals owe a great debt to Dr. Hamblin Smith, for his life's work was the study of wrong-doers and the cause of their misdoing. He found in his investigations that some of the worst wrong-doing was due to inherent disabilities. During his long tenure of office he made such use of his opportunities for studying both mental defect and mental disorder that scarcely a case of either passed through the Birmingham courts without being recognised by him. He rendered equal service in his addresses on the

psychology of the criminal, given at Birmingham University and Bethlem Hospital, which he continued after his retirement from the prison medical service. He was an impressive, sometimes even poetical speaker, and a lucid writer. After his retirement three years ago to Oxford Dr. Hamblin Smith became honorary physician to the education clinic there, but his closing years were saddened by the death of his wife and his only son.

**SIR HAMILTON BALLANCE, K.B.E., C.B.,  
M.D. Lond., F.R.C.S. Eng.**

We regret to announce the death of Sir Hamilton Ballance, consulting surgeon to the Norfolk and Norwich Hospital, which occurred in Norwich on Monday last.

Hamilton Ashley Ballance was the son of the late Charles Ballance of Stanley House, Clapton, the brother of Sir Charles Ballance, whose death occurred in February last, and the youngest and only survivor of four brothers who entered the medical profession. He received his preliminary education

at Mill Hill School and his medical education at University College Hospital, where he early distinguished himself by his success in examinations. He graduated as M.B., B.S. Lond. in 1892 with first-class honours in medicine and obstetric medicine and gained the gold medal in surgery. In the same year he took the diploma of F.R.C.S. Eng. later proceeding to the degrees of M.D. and M.S. Lond. He served the resident

posts at his hospital, became senior obstetric assistant at the hospital, and assistant demonstrator of anatomy in University College. With a view to gaining all-round experience, he then held for a time the appointments of resident medical officer to the Victoria Hospital for Children and the General Lying-in Hospital, Lambeth, after which he entered general practice in Norwich. In 1898 he was elected assistant surgeon to the Norfolk and Norwich Hospital, but obtained leave of absence to serve as surgeon to the Imperial Yeomanry Hospital during the South African War. On his return he rapidly acquired a large surgical practice. At the outbreak of the European war, Ballance, who held already military rank in the Territorials, became at once attached to the 1st Eastern General Hospital at Cambridge, and in 1915 he went to France as a consulting surgeon with the British Expeditionary Force. His services in France were recognised by repeated mention in dispatches, he became Colonel A.M.S., and at the close of hostilities was made a C.B. and later a K.B.E. On taking up his career in Norwich he continued to carry on and develop a fine surgical connexion, but his work was brought to a sad close a year ago by incurable illness. To a surgeon of Ballance's experience and accomplishment the issue was clear;

he retired from practice to face the inevitable with the greatest fortitude. He possessed in high degree the poise and sound judgment about men and affairs that was characteristic of his family. He took a leading but unobtrusive part in local medical politics, and for 14 years he represented the Eastern Counties on the Council of the Medical Defence Union. Always a man of few words, his words here became more infrequent as time went on, but whenever uttered they carried weight and were apt to determine the issue of a difficult problem.

A colleague at the Norfolk and Norwich Hospital sends the following tribute: "Ballance worked untiringly for the welfare of the hospital both as administrator and surgeon. In all directions he performed his duties pleasantly, courteously, and with dignity. He was a careful and skilful operator over a wide range of surgery, his work being based on an accurate knowledge of anatomy and pathology. He was a loyal and trusted colleague with whom it was a privilege and pleasure to work. His life and personality will be held in affectionate memory by a wide circle of friends and patients, and his colleagues at the Norfolk and Norwich Hospital will treasure his example. It is fitting that a surgical ward of the hospital should bear his name."

Sir Hamilton Ballance married the daughter of the late Rev. G. S. Barrett, D.D., of Norwich, by whom he had two sons and one daughter. He leaves behind him a fine record of accomplished work, and very many friends, private and professional, to regret the tragic abbreviation of his valuable career.

**JOHN GORDON HARROWER, Ch.M. Glasg.,  
D.Sc., F.R.C.S., F.R.S. Edtn.**

It is with deep regret that we have received news of the sudden death, following a surgical operation, of Prof. J. G. Harrower, of Singapore, at the early age of 46 years. We owe to Sir Grafton Elliot-Smith the tribute which follows:—

"Prof. Harrower received his primary education at Shields-road School, Glasgow, and at 11 years of age was awarded two bursaries which enabled him to continue his education at Allan Glen's Higher Grade School, where he became an apprentice in an engineering shop. Then he joined the electrical power station of the Glasgow Corporation Tramways as a shift engineer. During his apprenticeship he attended the classes of the Royal Technical College, Glasgow, and incidentally acquired that mathematical skill which is revealed in his biometrical researches in craniology. He became so interested in electrical engineering, theory and practice, that he had the idea of devoting his medical career to practice in X ray work and radiology, but soon abandoned this intention.

"After a brilliant career as student and junior teacher in the University of Glasgow, which afforded him the opportunity of displaying his ability and versatility, he was appointed professor of anatomy in the King Edward VII. medical college at Singapore and went out to the Federated Malay States. There he was able to cultivate his interest in surgery, and eventually became consulting surgeon in the general hospital. The teacher of such intelligent students as the Chinese and Malays of Singapore soon realises that the essential discipline of instruction is to arouse the students' curiosity and encourage them to solve their problems by direct observation. Harrower realised that the best way to effect his purpose was to show them by his own example that research

SIR HAMILTON BALLANCE

(Photograph by Russell)

was the only means to cultivate interest and efficiency, and he at once plunged into research in anatomy and anthropology. In touch with the Raffles Museum he developed interest in the tree-shrews and in the lemuroid *nycticebus* and, like his nearest neighbour in the world of anatomy, Prof. Le Gros Clark, he became intensely interested in what the latter has called the 'earliest forerunners of man' and also in the human bones which were dug up in the Federated Malay States. In the dissecting-room he investigated the anatomy of the Chinese coolies, and not only did the usual recording of anomalies but also made intensive studies of the crania of different groups of coolies, the results of which were published in the *Transactions* of the Royal Society of Edinburgh and in *Biometrika*. This work raised criticism among his colleagues, who expressed doubts whether it was proper for a teacher to spend his time in this way. Harrower, who regarded research as the one thing that made life worth living in his isolation, fought for his rights and won his footing. But his research accomplished more. It brought him into contact with other anatomists of similar interests—Prof. O. Hill, of Colombo, Prof. J. Shellshar, of Hong-Kong, and Prof. Davidson Black, of Peking, so that he no longer was oppressed by isolation.

"As an influential link in this chain of British anatomists in Eastern Asia, Harrower played an important part in maintaining British prestige in medical education, and his death is a serious loss to the Far East."

Prof. Blair, regius professor of anatomy in Glasgow, formerly a fellow student of Prof. Harrower, writes: "What Harrower said or implied with reference to his interest and ability in teaching is nothing short of the truth, for he left behind with his fellow students a reputation as a brilliant teacher, of strong and forceful personality, and a man respected and admired."

#### PROF. ROBERT BÁRÁNY

As we announced last week, Prof. Bárány, the otologist, died on April 8th at Upsala in Sweden, which had become his second home. It was in Vienna, where he was born, that he first attained his great reputation. A graduate of the university there, he went in 1901 to Frankfort and Freiburg, and then for a short time to Paris—"to learn more than the rest," as he said to his friends. On returning to Vienna in 1903 he found a place in the aural clinic of Adam Politzer, then the Mecca of the specialty. Very soon his attention was directed to the nervous system of the ear and its connexions with the eyes, and he endeavoured to discover a new anatomical and pathological basis for disorders affecting them, and hence for the treatment of these disorders.

As he said in the lecture delivered later in Stockholm when they gave him the Nobel prize, his attention had been caught by the rhythmic nystagmus caused by syringing the ears with water. He soon found out that this had something to do with the temperature of the water, and by patient observation he was able to analyse the factors governing labyrinthine irritation. This work produced order out of chaos and has furnished otologists with a reliable and valuable method of examination. Bárány's observations dovetailed into those of Ramón y Cajal and Bolk, and meant a big advance in the diagnosis of disease of the brain and the localisation of tumours, especially those of the cerebellum. His first reports were published in 1906, three years

after he entered the Politzer Clinic, and though at first his ideas met with much scepticism—not to say ridicule—they soon won support abroad, and by 1910 were generally accepted. In 1908 he had been made Dozent (or teacher) in the University of Vienna, but his work was interrupted by the outbreak of war, on which he was called to the colours. He saw active service and was captured by the Russians; and it was during his imprisonment that he learned of his election as Nobel prizeman in medicine for 1914. He was the first Austrian to win a Nobel prize; and he was a Jew. The Russians were generous enough to release their celebrated prisoner, and in Sweden, on his way home, he was asked to take over the Upsala chair of otology. Not being altogether happy in Vienna he gladly accepted the offer, and in Sweden he made for himself a great name as an aural surgeon and an authority on head injuries. The surgical treatment of deafness, of sinus disorders, and of cerebral and cerebellar abscess were his favourite field of work, but professional interests did not prevent his attaining eminence also as philanthropist, pacifist, and humanist. It was on his initiative that in 1929 an International Academy of Politics and Social Science for the Promotion of World Peace was founded in Sweden: he was convinced that only "increase of knowledge, science, and insight would bring about final understanding among the nations," and he worked intensely at this problem. He was a prolific writer and for a time editor of several scientific journals.

Rather delicate in boyhood, Bárány was never very strong, and he never quite got over the effects of military service and captivity. After going to Upsala he became thoroughly Swedish, a faithful son of his new country; but he did not forget Vienna, to which his heart always drew him back. This week he would have reached the age of 60 and there was going to be a presentation to him from otologists throughout the world, who wished to express in this way their respect and admiration. But the occasion for rejoicing has been changed to one of mourning for an untimely death.

He leaves five sons.

#### ARTHUR BALDWIN DUEL, M.D. Harvard, F.A.C.S.

Dr. Arthur Duel, who has died in New York, will be remembered here for his association with the late Sir Charles Ballance in the surgical treatment of facial nerve injuries. Dr. Duel, on his own initiative, erected an experimental station in the grounds of his country home outside New York, and invited Ballance to carry on there his experimental work on nerve anastomosis and grafting. As the result of this coöperation Duel was able to elaborate and perfect his technique of nerve grafting for facial paralysis, and to use it in the treatment of over seventy cases. It is for others to assess the final results of this operation, but it can be said that it has already justified itself as a method of treatment, although it is one which demands a perfect technique and unremitting attention during the post-operative period. Filled with a boyish enthusiasm and a keenness for his work, Duel tested out his ideas and methods experimentally, making failures teach him and not allowing them to depress him.

"A few months ago," writes Dr. John Beattie, "Duel sketched out to me his plans for an attack on the problem of the 'tic' which he noted during the period of recovery in his human patients. His experiments were always simple, carefully planned,

and carried out with a surgical technique which was a joy to watch. Duel had a charming personality. Well-beloved by his contemporaries he occupied the highest offices in his own field of work, and enjoyed the friendship of those in the United States who were and are endeavouring to secure for medical research its proper place in medical education and post-graduate training. His lectures on his own speciality were simple and direct, neither claiming

too much for his method nor decrying the efforts of others."

Those who listened to Dr. Duel's lectures at the Royal College of Surgeons of England in October, 1934, will remember the stress he laid on sound principles, good handicraft, and the use of the experimental method in the development of surgery. The profession in America has lost a leader and we in this country a friend and admirer.

## PARLIAMENTARY INTELLIGENCE

### NOTES ON CURRENT TOPICS

#### Reassembly after Easter: The Budget

THE House of Commons reassembled on Tuesday, April 21st, after the Easter recess.

Mr. CHAMBERLAIN, Chancellor of the Exchequer, in his Budget statement said that his total revenue from all sources on the present basis was £776,606,000. The expenditure on the basis of the Estimates was £797,697,000, leaving a deficit of £21,291,000. Dealing with minor changes in taxation which he proposed, the right hon. gentleman referred to various methods of tax evasion which, he said, were being practised within the existing law. He said that an individual in this country could now avoid tax by transferring property to persons abroad though he himself retained control of the property and enjoyed the income arising therefrom. It was proposed that income arising from such property should be taken as the measure of taxable liability. Provisions of the existing law designed to avoid loss of surtax arising from manipulation of "one-man" companies at home had been proved to be defective. They would be strengthened to meet new devices to escape tax liability. These two proposals related mainly to surtax and necessary changes in the law would take effect as from 1935-36, surtax in respect of which was due in the current year. These changes were estimated to yield the revenue £2,000,000 in the current year and £4,000,000 in a full year. Another form of tax evasion, the Chancellor of the Exchequer said, was being carried on by means of so-called educational trusts. A parent signed a deed giving part of his income to his child and as guardian received that income from himself and used it for his child's maintenance and education. The parent did no more for his child than he would have done anyhow, but he obtained relief from income-tax on this income. This practice, said Mr. Chamberlain, was becoming widespread and was unfair. He proposed to amend the law so as to provide that the income-tax liability of parents would not be affected by these educational trusts. Legislation would take the form that any income of an infant and unmarried child which had been in any way derived from the parent should be aggregated with the income of the parent for all purposes of income-tax. Any income enjoyed by the child from other sources would not be affected. It was estimated that this proposal would yield a saving in a full year of £2,500,000. This saving would be applied to a continuing process of giving relief to those taxpayers who were so hard hit in 1931. Children's allowances would be increased from £50 to £60 (a higher level than ever before) for every child. The cost of this concession this year would be £1,000,000, and in a full year £2,000,000. The general allowance for married persons would be increased from £170 (to which it was raised last year) to £180. The cost (to be found from the general resources of the Exchequer) would be £1,000,000 this year and in a full year £2,000,000.

At present Estate Duty was not chargeable on personalty abroad which had been the subject of a gift or joint investment or foreign settlement. Advantage was being taken of this to place property outside the scope of the charge. It was proposed to

place personalty abroad in the same position in this respect as personalty at home. A surtax of £1 a barrel was to be imposed on imported beer coming from non-Empire countries; there would be no alteration in respect of Empire beer. The Finance Bill would give effect to the recommendations in the recent report of the Committee on Key Industry Duties—i.e., the duties would be continued for a further 10 years, with some modifications and additions, and with provision in certain circumstances for variation of the duties from time to time. The net result of these minor changes was estimated to be an increase of revenue amounting to £1,025,000, thus reducing the deficit to £20,266,000. The Road Fund's surplus of £5,250,000 would be taken into the Exchequer. The standard rate of income-tax would be increased by 3d. in the £, giving an estimated yield in the current year of £12,000,000. The duty on both Empire and foreign tea would be increased by 2d. per lb. thus preserving the preferential margin of 2d. per lb. From this source it was estimated that the revenue would receive in the current year £3,500,000. The provision in the present Budget for defence was £50,000,000 more than that in the 1935 Budget. The final balance showed an estimated revenue of £798,381,000 and an estimated expenditure of £797,897,000, leaving an estimated surplus of £484,000.

Reviewing the national finances of the past four years Mr. Chamberlain pointed out that in 1932 old age and widows' pensions, health insurance, housing, and education required a little less than £121,500,000. In 1936 the estimated expenditure on these services was nearly £138,000,000. The aggregate present value of tax remissions made in Budgets from 1932-35 was over £50,000,000 a year.

### HOUSE OF COMMONS

TUESDAY, APRIL 21ST

#### National Health Insurance

Miss RATHBONE asked the Minister of Health what had been the total amounts under health insurance of the contributions paid and benefits received by male and female contributors, respectively, during 1935 or for the last period of 12 months for which figures were available.—Sir KINGSLEY WOOD replied: The following is the answer. The total amount of contributions received in the year 1934, the latest period in respect of which complete information is available, was £18½ million in respect of men and £8½ million in respect of women. In the same period payments on account of benefits, including medical benefit, which can be definitely classified on a sex basis amounted to £17,700,000 for men and £10,100,000 for women. In addition a sum of £2,580,000 was expended on additional benefits not in the form of cash, the division of which between men and women is not available.

ROYAL VICTORIA INFIRMARY, NEWCASTLE.—The board and governors of this hospital have decided to launch an appeal for £100,000 for extensions which include a pathological department and the opening of a new throat, ear, and eye clinic. The appeal for £150,000 made in 1927, to which Lord Runciman contributed £75,000, has only recently been realised.

## MEDICAL NEWS

### University of London

A recent examinations the following candidates were successful:—

D.P.H.

*Part I.*—Karl Biden-Steele, D. K. McI. Chalmers, Mabel J. Cooke, Florence A. Craig, Patience Craig, Janet M. Done, W. K. Dunscombe, Helen M. Evans, Jane O. French, Mary L. Gilchrist, G. E. Godber, Irene B. M. Green, Marjorie K. Hall, H. D. Holt, Joyce B. Jewson, Winifred A. Kane, Elsa V. McLaggan, J. A. R. Murphy, Eric Pereira, W. J. Pinto, G. D. Pirrie, Eleanor G. Porter, T. R. Rama Pai, M. J. A. Sandrasagra, L. D. Sarronwala, P. N. Sathe, B. K. Sikand, G. B. Smart, R. L. Tiruchelvam, and Evelyn A. M. White.

### University of Glasgow

On April 18th the following degrees were conferred:—

*M.D.*—R. T. Fletcher, Matthew Jackson, and E. A. Underwood (with high commendation); \*R. MacN. Buchanan (with commendation); A. T. Elder, John Hill, A. R. Miller, R. H. Moyes, \*Helen I. Robertson, and Elizabeth N. Young.

*M.B., Ch.B.*—Isidore Zerlin (with honours); R. A. R. Taylor, Aloysius Dunn, John Devine, and Solomon Mair (with commendation); Ian Aitchison, J. G. Aitken, G. McG. Barr, J. B. Barr, G. F. Boyle, J. G. Brown, J. L. Burnet, J. G. Cairns, Kenneth Cameron, Barbara C. Carmont, Leon Cohen, P. J. Connolly, Daniel Cryan, A. D. Cuthbert, Janet B. Dalgetty, Matthew Dantow, W. L. Girvan, C. W. H. Gourlay, W. J. Gray, J. H. Hamilton, R. M. Hoggie, Robert Hillman, K. C. Hutchin, J. M. Livingston, J. P. S. McConnell, R. S. McDougall, R. M. Maxwell, J. W. Miller, W. S. Miller, A. S. Moodie, R. A. Murphy, W. Y. Smith, W. A. McE. Stewart, H. A. Sutherland, Alice M. Taylor, W. J. Walker, David Watson, D. B. Watson, Mary G. W. Watson, Samuel Weinbaum, W. E. Whyte, A. L. Wilson, John Wishart, and C. N. Young.

\* In absentia.

Three Bellahouston gold medals were awarded to Dr. Thomas Nicol, Dr. J. B. Rennie, and Dr. W. R. Snodgrass, and the Macowen medal in surgery to Dr. R. G. Henderson.

### Scottish Conjoint Board

As a result of recent examinations of the conjoint examining board of the Royal Colleges of Physicians and Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow, the following candidates have been granted the diplomas of L.R.C.P. Edin., L.R.C.S. Edin., L.R.F.P. & S. Glasg.

Clarence Abramson, Ernst Brauer, C. P. Bringle, Ganapathi-pillay Chelvadoray, D. G. W. Clyne, Y. M. Dadoo, W. J. Ess, F. H. Feldman, Samuel Fertig, Margaret A. H. Godfrey, Manuel Green, F. H. Haine, A. D. Hoffmann, Mildred P. Hudson, C. K. Joannidis, Ludwig Jost, Edith L. Kander, William Lees, J. D. Milne, B. K. Palit, Tiberius Reiter, J. C. Reveilland, S. J. Shapiro, Kenneth Shepherd, Hermann Simchowit, D. D. Simmous, Irma Simon, O. F. Warner, Amin Wassef, C. M. Wells, and J. D. T. Wilson.

### Royal College of Physicians of Edinburgh

On Friday, May 1st, at 5 P.M., the Dr. Alexander Black lecture will be delivered to the college by Dr. J. D. Gilruth, who will speak on the Legend of Chiron, the Father of European medicine.

### Course on Applied Helminthology

Under the auspices of the University of London a course of lectures on applied helminthology with special reference to the control of agricultural and horticultural pests and the internal parasites of farm animals, poultry, and game-birds will be held at the London School of Hygiene, Keppel-street, W.C., from July 13th to 31st. Further information may be had from the secretary of the school.

### Lectures on Individual Psychology

Under the auspices of the Medical Society of Individual Psychology Dr. Alfred Adler will give an address on Thursday, May 7th, at B.M.A. House, Tavistock-square, London, W.C., at 8 P.M. His subject will be the Psychological Approach, and tickets can be obtained free of charge on application to Margaret Watson Ltd., 15, Palace Chambers, Bridge-street, S.W.1. Dr. Adler will also deliver three public lectures in the Conway Hall, Red Lion-square, on May 11th, 12th, and 13th at 8 P.M. The subjects of these lectures will be the science of the individual personality, the science of social psychology, and the science of the prevention of neurosis and crime. The chairmen on these occasions will be Sir Walter Langdon-Brown, Dr. H. C. Squires, and Dr. W. Norwood East, and tickets are obtainable from Alfred Hays Ltd., 62, Strand, W.C.2.

### University of Manchester

Applications are invited from medical graduates of this university for two Dickinson scholarships, one in medicine and one in surgery. Further particulars will be found in our advertisement columns.

### Westminster Hospital Medical School

On May 11th and 12th an examination in chemistry and physics, with an English essay, will be held at this school for the allocation of four scholarships, of £75 each, to students preparing for a degree in medicine of an English university.

### British Red Cross Society

A course of seven lectures on air-raid precautions will begin on Friday, May 1st, at 5 P.M., at the house of this society, 9, Chesham-street, London, S.W.

### Orthopaedic Scholarship

Applications for the Lord Nuffield scholarship in orthopaedic surgery are invited before June 1st. The scholar will spend two years at the Wingfield-Morris Hospital, followed by three months' travel. Further information may be found in our advertisement columns.

### Flint Cottage Hospital

The foundation-stone of the children's Jubilee ward at this hospital has been laid. Half the cost of the ward is being contributed by the employees of Messrs. Courtaulds silk factory in Flint.

### Post-graduate Course at Freiburg

A medical post-graduate course is being held at Freiburg-in-Breisgau from June 28th to July 18th, at which members of the medical faculty will give lectures. Opportunity will be given for members of the course to take part in the work of the various clinics. Further information may be had from Dr. M. Bruecher, Schwimmbadstr. 8, Breisgau-i.-Br., Germany.

### Society for the Provision of Birth Control Clinics

A lecture on the theory and practice of contraception will be given by Dr. Gladys Cox on Friday, May 8th, at 6 P.M., at the Walworth Women's Welfare Centre, 153A, East-street, London, S.E. Practical demonstrations will be given on Friday, May 15th, at 6 P.M. and at 7 P.M. by Dr. Cox, and on Friday, May 22nd, at 6 P.M. and at 7 P.M. by Dr. Lynette Hemmant. Medical practitioners and students should apply for tickets to the secretary of the clinic.

### Fellowship of Medicine and Post-Graduate Medical Association

The following courses will be given shortly: psycho-logical medicine at the Maudsley Hospital (afternoons, April 27th to May 30th), medicine, surgery, and gynaecology at the Royal Waterloo Hospital (all day, April 27th to May 9th); while arrangements for May include courses in dermatology at St. John's Hospital (afternoons, May 1st to 29th), thoracic surgery at the Brompton Hospital (all day, May 11th to 16th), urology at St. Peter's Hospital (all day, May 18th to 30th), proctology at the Gordon Hospital (all day, May 25th to 30th), venereal diseases at the London Lock Hospital (afternoons, May 25th to June 20th). Week-end courses will be held in May on infants' diseases at the Infants Hospital (May 2nd and 3rd), in chest diseases at the Brompton Hospital (May 9th and 10th), and in surgery at the Cancer Hospital (May 16th and 17th). Courses in June will include an evening M.R.C.P. clinical and pathological course at the National Temperance Hospital; an evening M.R.C.P. clinical course in chest and heart diseases at the Victoria Park Hospital; an afternoon neurology and psychotherapy course at the West End Hospital for Nervous Diseases, and week-end courses in medicine at the Prince of Wales's General Hospital; in obstetrics at the City of London Maternity Hospital; in fevers at the Park Hospital; and in surgery at the Prince of Wales's General Hospital. Courses arranged by the fellowship are open only to members and further information may be had from the secretary of the Fellowship, 1, Wimpole-street, W.

**An Expedition to Lapland**

In our advertisement columns, Surgeon-Commander Murray Leveck invites application for membership of an expedition to Northern Lapland next August and September. It is organised by the Public Schools Exploring Society; one or two honorary physicians or surgeons are required.

**National Association for the Prevention of Tuberculosis**

The council of this association has appointed Lt.-Col. Gordon G. Jolly to the post of secretary-general. Lt.-Col. Jolly is at present officiating public health commissioner with the Government of India.

**Royal Institution of Great Britain**

On May 1st Major W. S. Tucker, director of acoustical research at the Air Defence Experimental Establishment, will give the first of the Friday evening discourses since Easter. He will speak on direction finding by sound. On May 8th Sir William Bragg, P.R.S., will give his second lecture on the electric properties of crystals, and on May 15th Sir Richard Gregory, F.R.S., editor of *Nature*, will speak on Science in a Changing World. The discourses will be held at 9 p.m. at 21, Albemarle-street, London, W.

**New Health Centre**

Southwark borough council is erecting a health centre in Walworth-road at the cost of over £36,000.

**New Dispensary at Lincoln**

The Mayor of Lincoln has opened a new dispensary attached to Lincoln General Hospital. It has been erected on a slum-cleared site at a cost of £4000.

**St. Leonard's Hospital, Sudbury**

A new wing to this hospital is to be erected as a local monument to the late King. The hospital was built in 1868 and a sum of £5000 will have to be raised.

**Plight of the Cornish Hospitals**

It is stated that the West Cornwall Hospital at Penzance needs at least £20,000 for extensions, and the Royal Cornwall Infirmary at Truro £40,000, while the West Cornwall Miners and Women's Hospital at Redruth must have another 20 beds. All three hospitals are badly overcrowded.

**Carmarthen County Infirmary**

A new maternity wing and other extensions are to be added to this hospital at an estimated cost of £15,000, of which some £8560 has already been subscribed. The foundation-stone is to be laid on May 14th and when the extensions are completed there will be accommodation for 56 more beds.

**Hampstead General Hospital**

This institution is faced with a debt which has risen from £4250 at the end of 1934 to £8240 at the end of 1935. The rebuilding and enlargement of the X ray and massage department has been made possible through a donation of £8500 and it will be opened by Princess Helena Victoria on April 30th.

**Kettering General Hospital**

The daily average of occupied beds for 1935 at this hospital was 91.97, as against 76.25 in 1934. The average cost per patient, without making any allowance for the cost of out-patients, was £10 3s. 4½d. as compared with £9 10s. 7½d., and the average cost per occupied bed has increased by 8½d. The hospital guild weekly contributory scheme collected the record amount of £7393, which is an increase of £62.

**Royal West Sussex Hospital**

At the annual meeting of this institution it was stated that last year expenditure exceeded income by about £1800. Unless more money is received the hospital will have to draw upon its invested funds which amount to about £18,000. Expenses are increasing as the building is 111 years old and frequent repairs are necessary. The chairman said that if someone would give them £100,000 so that they "could knock the place down" and have a new building the cost of maintenance would be far less.

**INFECTIOUS DISEASE**

IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 11TH, 1936

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1788; diphtheria, 959; enteric fever, 18; pneumonia (primary or influenzal), 757; puerperal fever, 33; puerperal pyrexia, 95; cerebrospinal fever, 28; acute poliomyelitis, 2; encephalitis lethargica, 5; dysentery, 19; ophthalmia neonatorum, 79. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 17th was 6790, which included: Scarlet fever, 990; diphtheria, 1033; measles, 3428; whooping-cough, 625; puerperal fever, 14 mothers (plus 7 babies); encephalitis lethargica, 282; poliomyelitis, 5. At St. Margaret's Hospital there were 29 babies (plus 14 mothers) with ophthalmia neonatorum.

*Deaths.*—In 121 great towns, including London, there was no death from small-pox, 4 (1) from enteric fever, 103 (37) from measles, 2 (1) from scarlet fever, 36 (12) from whooping-cough, 28 (2) from diphtheria, 42 (14) from diarrhoea and enteritis under two years, and 57 (12) from influenza. The figures in parentheses are those for London itself.

There is a slight set-back in the mortality from measles, the figures for the last eight weeks (working backwards) being 103, 81, 104, 114, 105, 84, 88, 78 for the country as a whole, and 60, 43, 62, 62, 58, 47, 38, 18 for Greater London. Liverpool reported 9 deaths, Leeds 8, Barking, Leyton, Bristol, and Norwich each 3, no other great town more than 2. Gateshead had 4 fatal cases of whooping-cough, Liverpool 3. Deaths from diphtheria were reported from 14 great towns, 5 each from Liverpool and Sheffield, 4 from Hull.

The number of stillbirths notified during the week was 243 (corresponding to a rate of 40 per 1000 total births), including 39 in London.

**Medical Diary**

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

**SOCIETIES**

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, April 27th.

*Odontology.* 8 P.M. Mr. G. T. Hankey: Complete Caries of Erupted Permanent Dentition at the Age of 13—Agnesia of the Enamel. Dr. A. MacGregor: The Lymphatic System of the Teeth and Jaws.

TUESDAY.

*Medicine.* 4 P.M. Clinical Meeting at Charing Cross Hospital, W.C.

FRIDAY, May 1st.

*Otology.* Cases at 9.30 A.M., 10.30 A.M. Annual General Meeting. Dr. G. V. Th. Borries (Copenhagen): Diagnostic Problems in Orogenous Intracranial Complications. Mr. T. E. Cawthorne: Prescription of Aids to Hearing. Demonstration of Hearing Aids.

*Laryngology.* Cases at 4 P.M., 5 P.M. Annual General Meeting. Mr. W. S. Thacker-Neville: The Treatment of Quinsy by Tonsillectomy. Dr. G. V. Th. Borries (Copenhagen), Mr. F. J. Cleminson, and Dr. Gavin Young: Headache Associated with Disease in the Nose.

*Anaesthetics.* 8.30 P.M. Annual General Meeting. Dr. E. P. Poulton: The Future of the Oxygen Tent.

FRIDAY and SATURDAY.

*Neurology.*

May 1st. Meeting in Amsterdam. Morning: Demonstrations at the Neurological Centre and Presentation of Cases in the Wards by Prof. B. Brouwer. Afternoon: Meeting of the *Amsterdamsche Neurologien Vereeniging*.

May 2nd. Morning: Demonstration of Neurosurgical Cases by Dr. Oljenick.

*Odontology.*

May 1st. Meeting in Birmingham. 7.15 P.M., Dinner at Union Club. Mr. C. M. Strong: Pathology and Treatment of Dental Infection of the Antrum.

May 2nd. 10 A.M. (Medical Institute). Mr. Harold Round and Dr. H. J. R. Kirkpatrick: Bacteriological Infections of the Mouth. 11.15 A.M., Mr. Hugh Donovan, Mr. Russell Green, Dr. Baylis Ash, Prof. Humphreys, Mr. Harold Round, Colonel Broderick, Mr. Sampson, and Mr. Strong will show Clinical Cases. Mr. John Bunyan: The Injection Technique for Taking Plaster Impression.

**WEST LONDON MEDICO-CHIRURGICAL SOCIETY.**  
FRIDAY, May 1st.—8 P.M. (West London Hospital), Sir James Walton, Dr. Maurice Shaw, Prof. E. C. Dodds, and Dr. H. W. Post: Diseases of the Stomach.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

#### UNIVERSITY OF BIRMINGHAM.

TUESDAY, April 28th.—3.30 P.M. (Children's Hospital, Ladywood-road), Mr. R. A. Broderick: Dental Aspects and Treatment of Cases of Cleft Palate and Hare-lip in Children.

THURSDAY.—4 P.M., Prof. W. W. C. Topley, F.R.S.: The Mechanisms of Immunity: the Antigen-antibody Reactions. (First William Withering Lecture.)

FRIDAY, May 1st.—3.30 P.M. (Queen's Hospital), Mr. Bernard Ward: Treatment of Retention of Urine in General Practice.

#### BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane-road, W.

MONDAY, April 27th.—2.15 P.M., Dr. Duncan White: Radiological Demonstration. 3.30 P.M., Mr. Frank Cook: Dysmenorrhœa.

TUESDAY.—2 P.M., Prof. E. H. Kettle: Pathological demonstration. 3 P.M., Dr. A. A. Miles: Extensions of the Widal Test.

WEDNESDAY.—Noon, Clinical and pathological conference (medical). 2.30 P.M., Clinical and pathological conference (surgical).

THURSDAY.—2.30 P.M., Dr. W. S. C. Copeman: Arthritis. 3 P.M., Dr. Chassar Moir: Operative Obstetrics.

FRIDAY, May 1st.—2.15 P.M., Dr. A. A. Davis: Gynaecological Pathology. 5 P.M., Sir James Walton: The Surgical Aspects of Dyspepsia.

Daily, 10 A.M. to 4 P.M., medical clinics, surgical clinics or operations, obstetric and gynaecological clinics or operations.

#### FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, April 27th, to SUNDAY, May 3rd.—MAUDSLEY HOSPITAL, Denmark Hill, S.E. Afternoon course in psychological medicine.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. All-day course in medicine, surgery, and gynaecology.—INFANTS HOSPITAL, Vincent-square, S.W. Sat. and Sun., course in infants' diseases.—Courses open only to members of the fellowship.

#### HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

WEDNESDAY, April 29th.—2 P.M., Dr. Wilfrid Sheldon: Oesophageal Obstruction. 3 P.M., Dr. G. H. Newns: Morbid Anatomy of the Intestinal Tract.

Out-patient Clinics daily at 10 A.M. and ward visits at 2 P.M.

#### NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Marylebone-road, W.

WEDNESDAY, April 28th.—5.30 P.M., Dr. John Parkinson: Aneurysm.

#### MANCHESTER ROYAL INFIRMARY.

TUESDAY, April 28th.—4.15 P.M., Mr. Wilson H. Hey: Round About Peptic Ulcer.

FRIDAY, May 1st.—4.15 P.M., Dr. William Brockbank: Demonstration of Medical Cases.

#### GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

WEDNESDAY, April 29th.—4.15 P.M. (Western Infirmary), Mr. J. Mill Renton: Toxic Goitre and its Treatment.

Glasgow, Southern General Hospital.—Deputy Med. Supt. £500. Grocers' Company, Grocers' Hall, E.C.—Three Medical Research Scholarships. Each £300.

Hastings, Royal East Sussex Hospital.—Locum H.S. £5 5s. per week.

Hertford County Hospital.—H.S. At rate of £180. Heston and Isleworth Borough.—Asst. M.O.H. and Sch. M.O. £500. Home Office, Whitehall, S.W.—Medical Inspector for Children's Branch. £138.

Hospital for Sick Children, Great Ormond-street, W.C.—Res. M.O. for County Branch. At rate of £250. Also Surg. Reg. £200.

Hove General Hospital.—Hon. M.O. for Brighton Branch. Hull, Beverley-road Institution.—Asst. M.O. £350.

Hull Royal Infirmary.—H.P. to Sutton Branch Hospital. At rate of £160. Also Second Cas. O. At rate of £150.

Infants Hospital, Vincent-square, Westminster.—H.P. At rate of £75.

Ipswich, East Suffolk and Ipswich Hospital.—Orthopaedic Surgeon. £500. Cas. O. £168. Also H.S. £144.

Leeds, St. James's Hospital.—Res. M.O. Also Res. Surg. O. Each £350.

Leicester, City Isolation Hospital and Sanatorium, Groby-road.—Jun. Asst. M.O. At rate of £300.

Leicester Royal Infirmary.—Hon. Asst. Radiologist. Leyton Borough.—Temp. Asst. M.O. 10 guineas per week.

Liverpool Sanatorium, Delamere Forest, Frodsham.—Second Asst. to Med. Supt. £200.

Llanelli Borough.—Asst. M.O.H. and School M.O. £500.

London County Council.—Sen. Asst. M.O.'s, Grade II. Each £500. Also Asst. M.O., Grade II. £250.

London Jewish Hospital, Stepney Green, E.—Res. M.O. and H.P. At rate of £150. Also H.S. and Cas. O. Each at rate of £100.

London Lock Hospital, 283, Harrow-road, W.—Res. M.O. to Male Depts. At rate of £175.

Macclesfield General Infirmary.—Second H.S. At rate of £150.

Manchester, Ancoats Hospital.—H.S. for Ear, Nose, and Throat Dept. At rate of £100.

Manchester, Baguley Sanatorium.—Jun. Asst. M.O. At rate of £250.

Manchester Royal Children's Hospital, Pendlebury.—Res. Surg. O. At rate of £125.

Manchester Royal Infirmary and University.—Dickinson Scholarships. £300 and £75.

Margate, Royal Sea-Bathing Hospital.—H.S. At rate of £200.

Mount Vernon Hospital, Northwood.—H.S. At rate of £150.

National Temperance Hospital, Hampstead-road, N.W.—H.P. At rate of £100.

Newcastle-upon-Tyne Education Committee.—Asst. School M.O. £500.

Northampton General Hospital.—H.S. At rate of £150.

Norwich, Norfolk and Norwich Hospital.—H.S. Also Cas. O. Each £120.

Nottingham City Mental Hospital.—Jun. Asst. M.O. £350.

Nottingham General Dispensary.—Res. Surgeon. £250.

Oxford, Wingfield-Morris Orthopaedic Hospital, Headington.—Lord Nuffield Scholarship in Orthopaedic Surgery. £200.

Penshurst, Cassel Hospital for Functional Nervous Disorders, Swanlands.—Locum tenens. 10 guineas per week.

Plymouth, Prince of Wales's Hospital, Greenbank-road.—Res. Anaesthetist and H.S. to Special Depts. Also H.S. Each at rate of £120.

Princess Beatrice Hospital, Earl's Court, S.W.—Res. M.O. At rate of £150.

Princess Elizabeth of York Hospital for Children, Shadwell, E.—Res. M.O. At rate of £200.

Princess Louise Kensington Hospital for Children, St. Quintin-avenue, W.—H.S. At rate of £100.

Queen's Hospital for Children, Hackney-road, E.—H.P. and Cas. O. Each at rate of £100. Also Clin. Asst. to Surgical Out-patients. 5s. per attendance.

Radcliffe-on-Trent, Notts. County Mental Hospital.—Second Asst. M.O. £459.

Redhill, Royal Earlswood Institution.—Jun. Asst. M.O. At rate of £250.

Rotherham Hospital.—H.P. £180.

Rotherham, Oakwood Hall Sanatorium.—Asst. M.O. £300.

Royal Naval Medical Service.—M.O.'s.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Res. Cas. O. £150. Also H.P. At rate of £100.

St. Albans, Hill End Hospital for Mental and Nervous Disorders.—H.P. At rate of £165.

St. Bartholomew's Hospital, E.C.—Surgeon.

St. Thomas's Hospital, S.E.—Visiting Anaesthetist.

Sheffield Children's Hospital.—H.S. At rate of £100.

Shorham-by-Sea, Southlands Hospital.—Part-time Radiologist. At rate of £125.

Southampton County Borough.—Asst. M.O.H. £500.

Southampton, Royal South Hants and Southampton Hospital.—Sen. H.S. £200. H.P. H.S. Also Res. Anaesthetist and H.S. to Ear, Nose, and Throat Dept. Each at rate of £150.

Stockport Infirmary.—H.S. and Cas. O. £150.

Stoke-on-Trent, North Staffordshire Royal Infirmary.—Second H.S. Also H.S. for Aural and Ophth. Dept. Each at rate of £150.

Surrey County Council.—Asst. M.O. £600. Also Jun. Asst. M.O. for County Sanatorium. At rate of £350.

Swansea County Borough.—Asst. M.O. £500.

Swansea General and Eye Hospital.—H.P. At rate of £150. Also Cas. O. At rate of £150-£175.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Jun. Res. H.S. At rate of £100.

Winchester, Royal Hampshire County Hospital.—H.S. At rate of £125.

Wolverhampton Royal Hospital.—H.P. At rate of £125.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Banbury (Oxford).

## Vacancies

For further information refer to the advertisement columns

Aclon Hospital, W.—Hon. Consulting Surgeon.

Altrincham General Hospital.—Jun. H.S. At rate of £120.

Aylesbury, Royal Buckinghamshire Hospital.—Second Res. M.O. At rate of £150.

Barnstaple, North Devon Infirmary.—Res. M.O. At rate of £150.

Birmingham and Midland Eye Hospital.—Res. Surg. O. £200.

Birmingham, Selly Oak Hospital.—Jun. M.O. At rate of £200.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. At rate of £120.

Bradford Royal Infirmary.—Two H.S.'s. Each at rate of £135.

Bristol, Southmead Municipal General Hospital.—Jun. Asst. Res. M.O. At rate of £200.

Burton-on-Trent, General Infirmary.—H.P. and Cas. O. £150.

Canterbury, Kent and Canterbury Hospital.—H.S. At rate of £125.

Cardiff, King Edward VII. Welsh National Memorial Sanatorium.—Asst. Res. M.O. for Glan Ely Tuberculosis Hospital. £200. Also Res. M.O. for Kensington Hospital. £350.

Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W.C.—Third Res. H.S. At rate of £75.

Charing Cross Hospital, W.C.—Hon. Clin. Asst.

Chester City Hospital.—Sen. Res. M.O. £100.

Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall, Gl. Barrow.—H.P. At rate of £150.

Coventry and Warwickshire Hospital.—Res. H.P. £160. Also Res. H.S. £125.

Doncaster, Royal Infirmary and Dispensary.—Res. Anaesthetist. Also H.S. Each at rate of £175.

Durham County Council.—District Tuber. M.O. £500.

Ealing, King Edward VII. Memorial Hospital.—Sen. Res. M.O. At rate of £250.

Eastbourne, Royal Eye Hospital, Pevensy-road.—H.S. £275.

Evclina Hospital for Sick Children, Southwark, S.E.—Part-time Pathologist. £250-£300.

Exeter, Devon Mental Hospital, Erminster.—Jun. Asst. M.O. £350.

Glamorgan County Council.—Med. Supt. for Penrhwytn Infirmary, Neath. £500.

## NOTES, COMMENTS, AND ABSTRACTS

## FEAR IN CHILDHOOD

BY HILDA WEBER, M.D., B.Sc., D.P.M.

PHYSICIAN TO THE INSTITUTE OF MEDICAL PSYCHOLOGY AND TO  
THE BRITISH HOSPITAL FOR MENTAL DISORDERS AND  
NERVOUS DISEASES, LONDON

FEAR is a danger signal evolved in the interests of race- and self-preservation. It has therefore ultimately a protective purpose. But, invaluable as a temporary measure, its continued existence is harmful. It is not merely that the condition of the body and mind to which it gives rise is injurious to the general welfare of the organism, but its very presence indicates that some exciting cause remains; fear and anxiety can in fact only be treated rationally when it is recognised that they are but symptoms.

For these reasons fear, with its derivative anxiety, lies at the basis of much ill-health. None the less, the value of fear as a danger signal remains; like pain it warns the individual of some threat to his welfare. Its presence in some cases, therefore, is normal, and the nature of its origin requires discrimination. It is the purpose of this paper to draw attention to this aspect of the question, for disregard of the protective function of fear is not only frequent but also has deleterious results. In the course of everyday life, for instance, the sensitive child is likely to find his doubts and fears met with lack of understanding, possibly with impatience, even reproof. Bewildered, with guilt added to an increased sense of fear, initiative and ability receive a severe check. At the same time the child may feel resentment, even hate, for those who have given in place of help an added load of difficulty. Some of the problems and delinquencies of childhood may well find their root in such a situation.

While ignorance explains much of this intolerance, it is more difficult to account for the small attention which medicine pays to the protective function of fear. Yet it is common knowledge that those species of animals which do not possess the capacity for fear have other means of defence at their disposal: the tortoise finds protection in the thickness of his shell, the skunk in the terrible odour with which he is able to repel his enemies. Similarly it is no chance happening that the existence of those animals who can experience fear depend at times upon defence or flight: for, in keeping with its position as an emergency reaction, fear prepares the organism to meet the need which such a situation requires. Well recognised as are these facts in the medical world, certain considerations suggest that medical practice and theory pay them insufficient attention. The following case-history may serve as a useful introduction to the subject.

## A Case of Fear

To be afraid of one's own shadow is a phrase popularly used to indicate excessive timidity. It is, however, so seldom met with that, apart from the intrinsic interest of the case itself, its occurrence in actual practice seems worth recording.

Thelma, an intelligent child of 19 months, was walking along the street with her mother one winter's evening, when, observing her own shadow cast by the light from a standard lamp behind her, she became filled with terror. Clinging to her mother she met any attempt to make her stand on the ground with passionate and frightened crying. Her mother, seeing how great was her terror, carried her home, thinking the phase would pass. She was mistaken. Not only did the child on her return home show the same dread of shadows, but in the course of the next nine days matters went from bad to worse.

Thelma's whole outlook became increasingly dominated by fear. The previously happy and

contented child, who had thoroughly enjoyed a romp, and yet would play for hours by herself when her mother was busy, now cried and demanded constant attention. She would not be left alone. Her parents, who had hitherto found her training an easy task, now found themselves in a quandary. They realised the danger which they ran of hopelessly spoiling the child; she was indeed beginning to dominate them with her screams and cries. But, they asked, what else could they do? If they left her to "cry it out" might not this make her ill? They received with relief the advice not to follow this course, which might well resolve itself into meeting fear with fear, and so could only increase the trouble. The aim of treatment was to make the more mature goal of adequate independence and coöperative action more acceptable than her present regressive mode of behaviour. When the subject of treatment was so explained the parents willingly coöperated in the ensuing interview, the main outlines of which follow.

The age of the child (19 months) precluding arguments by words, the possibility presented itself that the method used in overcoming fear in animals might have value. Two main methods are employed in training animals—namely, fear and kindness. Yet not only is fear a bad master, but to use it where fear is already in existence is but to increase the original trauma; at best it can but cover up, it cannot remove the trouble. Kindness, based on an attempt to comprehend the situation, achieves its purpose without these defects. When a horse shies at a piece of paper, for instance, if he is led up to the, to him, terrifying object, it is possible so to accustom him that he learns he has nothing to fear. The same method of procedure was now adopted with Thelma.

After she had become accustomed to the room, and a doll had effectively paved the way to friendly relations with me, I suggested that her father, who had the child in his arms, should carry her to the wall opposite the window. I then showed her the shadows of her own hands, those of her doll, and of a ball on the end of a string. Secure in her father's arms she took interest in the game and tolerated the shadows well. When on my suggestion, however, her father lowered her to within reach of the ground she screamed with fear: it was as though, since she had been walking when the fear of her own shadow first overwhelmed her, association with the floor reminded her again of her own fear. Possibly also, when on the ground, she became more acutely aware of her own defencelessness.

On the principle of not regarding her behaviour as mere naughtiness but rather as symptomatic of the difficulties which she was encountering, she was not forced in any way. Instead I advised her father to sit on a couch with Thelma in his arms. Again feeling secure, she soon became free enough to take interest once more in our game with the doll and the ball. After a time we made a further step. Her father holding her, she stood on the couch without fear. But when, on my suggestion, he sat on the floor, she again became fearful. At length, however, by similar stages as before, she passed from his knee to the ground, at the same time that she played with the toys and became further accustomed to their and her own shadows. Gradually, becoming more and more at home, the wish for exploration took the place of fear, and before the end of an hour Thelma's whole attitude and expression had completely changed. Whining, terror, and undue dependence had given place to freedom of action, to the contentment of the happy and self-confident child. She seemed as though she had been relieved of a load and was thankful to be freed from the unknown dread which had pursued her for days.

Subsequent as well as immediate progress was also good. The mother wrote some weeks later to say that Thelma had never gone back since the interview.

It is true that she had hesitated occasionally for a moment or so for two or three days afterwards, but she quickly recovered her self-possession and had no return of her fears. On the contrary she played with her own shadow and called it "Thelma." She began to make progress in every way. Her appetite and sleep were good, she put on weight, and became a normal and happy child. The good results so quickly obtained were undoubtedly satisfactory. At the same time it must be conceded that they in part depended upon Thelma's previous history, as well as upon the comparatively short duration of the symptoms themselves. Up to the time of the onset of her fear of shadows Thelma had been apparently well adapted in every way. The home atmosphere favoured this state of affairs. The parents were well adjusted and were fond of each other and of their child. Thelma, herself, was forward and intelligent—by the time she was 8 months old she was saying simple words such as "Mum" and "Dad."

#### The Place of Fear in the Development of the Child Mind

This picture of an intelligent, happy, and seemingly well-adjusted child, in a good environment both material and mental, renders the more surprising the pathological fear of shadows which arose for no obvious reason. Two broad possibilities as to the origin of this fear present themselves—namely, that it was a manifestation of a hitherto latent conflict, or that it was an atavistic fear of the unknown. Certain considerations support the latter and simpler possibility.

It was in the interests of self-preservation that primitive man should regard the unknown with diffidence, even with fear. But the very purpose of fear as a danger signal implies some discrimination, and discrimination is useless if there is not some corresponding power of independent action. The absolute helplessness of the new-born infant consequently renders it not surprising that at the outset of life fear plays little part. The infant's powers of exteriorisation generally are indeed very meagre: even the special senses are but imperfectly developed. It is significant, therefore, that his increasing powers of discernment, essential for the equipment of the relatively self-sufficient individual, have a corresponding correlation with a growing capacity for independent action.

These changes, however, require time. Even when the child can recognise his mother, for a while he is indifferent to most of his surroundings. For this reason his early easy acceptance of the attentions of strangers appears to depend rather upon the indifference born of lack of perception than actual friendliness. Similarly his later shyness may well indicate less an accession of hostility than the advent of a developing awareness of the need to distinguish the harmless and useful from the possibly harmful.

In connexion with the acute fear which the sight of her lengthening shadow aroused in Thelma, it is relevant that movement not only more readily attracts attention than does rest, but it also suggests a greater measure of life. To one who is beginning to be aware of the possible dangers of the unknown, the moving object is therefore especially apt to cause terror. This in turn accounts for the great fear which the sight of her lengthening shadow first aroused in Thelma. It is true that she must have seen shadows before. On the other hand her fear of them may well have arisen from her first observation of them (as opposed to mere seeing). For advanced enough to observe her lengthening shadow—she was rather a precocious child—she was not yet able to express in words what she dreaded. After all, absence of fear does not necessarily mean courage. It may depend upon lack of observation. Some of the timidity which intelligent children often display may arise from early perception of objects combined with incorrect interpretation. Certainly treatment which enabled Thelma to accept shadows as part of her normal environment resulted in the disappearance

of her fears. Well-justified assurance took the place of the state of regression into which the condition of fear had cast her.

The dependence of children on their parents lends a further interest to the lasting good of this one interview. It suggests that they as well as Thelma had benefited. Certainly both had been present at the interview, and both had consciously recognised the goal of treatment—namely, the replacement of fear by well-justified confidence. These facts might well have influenced their later management of their child in the direction of better understanding; for any means which helps parents to a better understanding of the child has value. At this one interview comparison with animal life had suggested a method by means of which Thelma's fear of shadows was overcome. This fact suggests that the comparative approach may have a wider value in connexion with child life in general, and with their fears in particular. With this idea in view the following notes have been set down.

#### Points of Likeness Between the Child and Animal Mind

*General management.*—At the onset it is evident that the management both of children and animals has much in common. As a trainer once remarked, patience, firmness and understanding are always required in dealing with horses. Many an animal has been ruined by mistaking playfulness and high-spiritedness for viciousness: beaten for what was only a manifestation of health, the animal became vicious and sour. Surely such an opinion is well in keeping with much recent work with children, more especially when taken with his further remark that to lose one's temper is a sign of weakness which lowers the man in the animal's esteem. It may be that he was considering the horse from too anthropomorphic a point of view; the extent to which the behaviour of animals should be construed in human terms undoubtedly is a matter for very careful consideration. Nevertheless, with this reservation in mind, animals are in many ways so like children, and vice versa, that even cursory examination would suggest that the study of animal behaviour may have real value as an additional means of gaining insight into the workings of the child mind.

*Difficulties of discrimination.*—The difficulty which some animals find in distinguishing substance from shadow is a case in point. A dog I once knew could be worked up into a paroxysm of excitement whenever his master caused the light reflected from a glass to move about the floor; and it is not uncommon for a cat to play with shadows. But not only pleasurable excitement, fear may arise in animals in much the same way: the horse which shies at a piece of paper is an example. Experience suggests that incorrect interpretation may similarly be a primary cause of fear in children.

*Sense of guilt.*—None the less circumspection is always required when making deductions from material of this kind. There is not only the danger of anthropomorphising animal behaviour, but also the interpretation of child behaviour from too adult a standpoint, less often recognised, constitutes a real danger. An unconscious wish to justify his conclusions may well lead the adult to that over-generalisation from the particular which inevitably produces error. For instance, it is true, as Klein points out in her work on "The Psycho-analysis of Children," that children suffer from an early age from a sense of guilt. But not only does she ascribe this guilt to conflict or conscience arising from difficulties usually if not always of a sexual nature, but she also appears to attribute all pathological anxiety to this origin, at any rate she does not refer to any other. Now whether or no she is right in her contention that all psychoneurotic reactions have their basis in the anxiety of children, anxiety in childhood is so common that knowledge of its causation in general and of this theory in particular deserves investigation.

The subject matter of this paper renders it of interest that the study of animal life offers a definite alternative: for with animals there is no constant relation between either conflict or conscience on the one hand, and anxiety on the other. A hen, for instance, exhibits unmistakable anxiety when she sees the ducklings she has hatched swimming on the water: their position is to her a dangerous one. But to credit her with conscience in the matter would certainly seem far-fetched. As Lloyd Morgan says, where the workings of lower mental processes can fairly explain an instance of animal behaviour, there is no justification for attributing it to those which stand higher in the order of development.

*Evolution and the inherited response.*—On the whole an animal's response, untutored by experience, gives insight into its primitive needs. None the less, as natural selection alone shows, this is not always the case. Pitt's observations on the effect of the temperamental characteristics which distinguish the mouse *Eutamias glareolus* from *E. skomerensis* are relevant here. The two species of mice are similar in physical structure. But the former's quickness, wariness, and readiness to take alarm have enabled him to flourish in surroundings in which his brother's slower movements and over-trustfulness have allowed him to become a prey to his enemies. The survival value of fear here comes plainly into view.

*Environment and the inherited response.*—At the same time an inherited reaction, though of advantage in the environment in which it was evolved, may be unsuitable in another. A lover of animals has ascribed the action of the horse which shies at a piece of paper to lack of courage, and contrasts it to that of the cat which tends to pause and examine the unfamiliar object. This opinion may be correct. On the other hand, in a given environment what is wisdom for one species of animal may be rash, even suicidal, for another. A herbivorous animal, such as the horse, in the wild state is well advised to regard the unexpected with caution, as a possible source of danger. But a carnivorous animal, such as the cat, whose livelihood in part depends upon his readiness to track down and spring upon the suddenly appearing quarry, is in a somewhat different position. Some degree of preparedness to examine, maybe to follow the suddenly appearing object, has for him a definite survival value. Hunger is a powerful master, and where it impels the animal the possibility of food may drive fear into the background.

### Relation of Fear to Security

The needs of the moment, therefore, to some extent determine whether fear or interest predominate when the unknown is in question. The question of security to a large extent sums up the situation. It is ultimately in the service of self-preservation that the need for food is able to overcome fear. The question of security, that complement to fear, has in fact a special interest in connexion with the subject matter of this paper. Both endogenous and exogenous factors are concerned in this question. Well-justified assurance in one's own powers, whether physical or mental, contributes to the sense of security in a measure at least equal to that which external shelter or support may give. Examples of pathological fear and anxiety would even suggest that endogenous factors are if anything ultimately of the greater importance.

*Security a counter to fear.*—As a counter to the sense of fear the feeling of security need be but partial—but it must be sufficient to give the individual assurance from which he may grow. The small child, safe behind the shelter of his mother's skirts, dares then to peep out at the unknown and therefore to him terrifying stranger. The wise mother does not rebuff the child nor scold him for displaying fear. She may not recognise the emergence of an atavistic trait, a primal fear in the presence of the unknown, but she appears to realise the value of adequate though not pampering protection.

*The sudden and unexpected.*—Within certain limits anything which decreases the sense of security predisposes to fear. In this way a summation of factors may produce a state of terror. A loud noise is not necessarily in itself terrifying. Yet when it is unexpected it arouses fear even in the new-born infant. It is the same with the sudden loss of support, and as Watson points out, this to some extent remains throughout life. A man crossing a bridge, which remains quite steady until he reaches the middle when it begins to bend, shows real fear. On the other hand, both a loud noise and loss of support when associated with a well-balanced preparedness may arouse pleasure instead of fear (incidentally well-poised preparedness postulates a certain degree of security). The healthy child secure in his home usually loves a noise, and, as adults know to their cost, likes it all the more if he makes it himself. Not only is it expected, but possibly the knowledge that the noise is due to his own efforts gives him a sense of mastery, and that self-confidence which in itself lends a sense of security. It is the same with loss of support. The small child enjoys being tossed in the air by the strong and kindly adult—he knows that he will be safely caught. Possibly the sense of defying danger adds a spice to the situation. In phantasy it may be as though he were stepping forth into a dangerous country which his own prowess enables him to master. But some sense of security must be maintained—once the child has been dropped he will with difficulty, if ever, tolerate the game again.

*Repetition in child play.*—In other ways the need of security is of interest in connexion with children: for instance, the repetitive process which forms such a marked feature of their play. Repetition brings with it increasing familiarity, and familiarity, as contrasted with the unknown, brings with it a feeling of security. But just as a feeling of security follows upon past experiences to which the child has been able to adjust—e.g., by means of repetition—so, as Diethelm points out, the feeling of insecurity is based upon experience of the past to which the individual has not been able to adapt himself.

*Emotion and intelligence.*—For this reason intelligence plays a far more difficult part when an opposing "emotional set" has first been established. The well-trained polo pony is able to treat with unconcern the ball which by chance may pass between his legs on the polo ground. It is doubtful whether a pony not early trained could ever become so accustomed. Similarly with the child, early experience is of great importance: the youngest infant learns to inhibit painful reactions and repeats those which are pleasurable. But dependent though these responses directly are upon the emotions and automatic mechanisms, even at this early age intelligence plays some part. For instance, as Pritchard has pointed out, aments are with difficulty trained in good habits and broken of bad ones, whereas normal infants only acquire such bad habits if they are brought up wrongly.

### Management of the Child

The above observation indicates that good management is in line with the normal child's best interests, and rather contra-indicates a too "go-as-you-please" attitude to his upbringing. Not only maldirection, no direction at all may have serious results. Experience is not necessarily the best teacher. The burnt child avoids the fire, but nobody would suggest that this is the wisest method of education. Apart from actual physical injury, the experience tends to make it more difficult for the child to avail himself of the useful properties of fire, whilst avoiding the dangers.

*The child's need for guidance.*—In short, nothing absolves the adult from responsibility towards the children in his care. Man owes his pre-eminence in the animal world to his intellect, and, as with other powerful weapons for good and evil, the child needs some initial help in the use of this potent and flexible instrument of adaptation. It is true that the child mind demands play for the development of

individuality and personal initiative; but he also needs some guidance and authority upon which he can rely. But though intelligence can achieve much, the emotional rapport between parent and child is of great importance; mishandling of the emotional life may wreck the whole. The behaviour of the parent therefore deserves careful consideration. Excessive severity tends to be equated with tyranny, undue leniency with weakness, whilst inconsistency of conduct the child finds especially hard to bear—it gives him no firm ground from which to grow.

*The parent's attitude to the child's fears.*—Good poise on the part of the parent is of inestimable value in connexion with childish fears. The realisation that these fears, far from being "mere cowardice" or "just stupidity," are rather symptomatic of something amiss, encourages a more constructive view of the situation. His resultant greater tolerance not only improves the relations between parent and child but also opens the way to a truer understanding. The child finds, in place of a seemingly tyrannical authority, a friend to whom he can turn in times of difficulty and stress.

Such a secure but not over-protected child is in a fortunate position. The need for the requisite degree of security satisfied, the wish to investigate the unknown takes the place of fear. Learning by experience that he is able to manage the problems which he encounters, difficulties come to be regarded as opportunities for action, not as responsibilities to be dreaded. Fears of the present, instead of forming an obstacle to progress, are converted into a scaffolding for further growth, a further impetus to right development.

#### Conclusion

Insufficient attention to the basic function of fear as an emergency reaction with a direct relation to race- and self-preservation is pernicious. It accounts for some of that misunderstanding and consequent mismanagement of the child's problems and fears, which not only gives rise to present trouble, but also leads to much unhappiness, even illness, in after-life. Means therefore which assist to a right estimate of a child's fears deserve attention. Comparative medicine as one such avenue of approach is dealt with in this paper. It not only offers an additional means of access to the understanding of the child mind, helping in the correction of certain misconceptions, but it also illustrates the sometime value of fear as a protective reaction.

Both clinical material and examples from animal psychology support the possibility that some of the fears of childhood represent the survival of an atavistic attitude to the unknown. A certain degree of security is necessary for normal development: fear calls attention to some disturbance of this balance. Its very insistency which emphasises the urgency for better adjustment has practical justification; for fears, which neglected or otherwise mishandled, may become a danger; but wisely dealt with as they arise in early life, become a stimulus for healthy mental development. A wise spirit of adventure takes the place of doubt and fear.

#### RURAL HOSPITALS IN THE UNITED STATES

AMONG many other beneficent activities the Commonwealth Fund furnished the means to build, between 1927 and 1930, six 50-bed hospitals in rural areas of the United States. These hospitals steadily grew in popularity up to the time of the trade depression when there was a set-back from which they have now recovered, and in the first nine months of last year they showed an average daily occupancy of 23.3, a figure almost equal to the highest peak recorded in the like period in 1931. (It might be observed in passing that the vision of a hospital never more than half full may excite envy among British practitioners accustomed to the cry of "no beds.") Last August a seventh hospital was opened at Kingsport and an eighth, at Tupelo, is

already projected which, it is estimated, will serve a population of 100,000. For this hospital 2790 contributors have promised a local quota of \$40,000. Five of these rural hospitals are already financially self-supporting. At first resident physicians were paid for by the Commonwealth Fund, but this is no longer necessary. The hospitals are staffed by local physicians and treatment tends to be concentrated in the hands of a few men tacitly adjudged by their colleagues to be the best in the vicinity. The hospitals are essentially general hospitals, and of every five cases admitted, two are medical or obstetrical and three surgical. At Kingsport an experimental prepayment scheme by potential patients is already in operation. Employed persons, enrolling by groups, pay one dollar down and nine dollars annually which entitles them to 21 days free hospital service and also to certain discounts. Another three dollars per annum entitles the member to further discounts in respect of services rendered to his dependents. The report includes a racy account of an average week's work in one of these hospitals.

"The day's first patient is Minnie Dale. She has an abscessed eye, and the best man in six counties for that is Dr. Coleman. Dale, a bright young farmer, knows the hospital and likes it; his brother has been in it three times in the last six months, and the doctors made just one little mistake: they said he wouldn't get well but he did. The clerk tells Mr. Dale that the charges will be \$13; that is more than they counted on, but they have \$10 and pay it. Mrs. Dale goes to the table and Dr. Coleman removes a diseased tear-sac and tear-duct; the threatened eye is safe."

Again, "Mrs. Midnight . . . was the clinic's first patient. When she learned that she was tuberculous the family had \$200. She paid her doctor at \$5 a treatment while the money lasted."

It is to be presumed that all the characters are fictitious, but we confess we should like to meet Mrs. Midnight.

#### R.A.M.C. TRAINING

AT a time when the policy of "si pacem vis, para bellum" has been adopted as a political necessity, the appearance of this manual<sup>1</sup> is appropriate. It is divided into two parts. Part A is concerned with military training and includes three chapters on the all-too-pressing subject of anti-gas measures. Chemical weapons are classified according to their effect or site of election into four groups: choking, nose, tear, and blister. The signs, symptoms, and treatment, both preventive and remedial, of poisoning by all these, and also by prussic acid and carbon monoxide which, though not strictly chemical weapons, might be encountered on active service, are clearly explained, and it is noted that the box respirator does not protect against carbon monoxide. Individual measures against chemical weapons comprise, in addition to the respirator, the wearing of protective clothing which may have to be decontaminated by various means such as exposure to the air, or to steam, baking, and boiling. Collective anti-gas measures aim at neutralising the poisonous substances, keeping trenches and dug-outs free from gas, or ridding them from contamination if it occurs. Personnel contaminated with gas but not actually casualties are dealt with by their units and not by the R.A.M.C. Those who have become casualties are treated first in gas-treatment centres and, if also wounded, are subsequently evacuated by the R.A.M.C. The organisation of a gas-treatment centre is described and illustrated by diagrams, and the syllabus for anti-gas training is tabulated at the end of the chapter.

Part B, for the technical training of warrant officers, non-commissioned officers, and privates, is divided into three sections. The first two—on anatomy, physiology, first aid, and nursing—go rather more deeply into these subjects than the ordinary

<sup>1</sup> Royal Army Medical Corps Training 1935. London: H.M. Stationery Office, 1935. Pp. 438. 3s. 6d.

manuals. The third section deals with food and cookery, and appended to it is a table of foods in season with times required for their cooking. The manual, profusely illustrated with figures and diagrams, is compact with information of medico-military importance.

#### A SURVEY OF ARTHRITIS IN FINLAND

In 1934 plans were prepared for a sociological campaign against arthritis in Finland. The aid of the General Mannerheim's League for Child Welfare was invoked, and its visiting nurses, after hearing special lectures on the subject, undertook a house-to-house canvass of 37 rural communities with a population of 195,000 souls. As non-articular rheumatic affections, such as endocarditis, chorea minor, sciatica, and neuritis were not included, as a rule, in these nurses' inquiries, the information they collected concerned not so much rheumatic disease as a whole, as those arthritic manifestations which social workers can easily recognise. It was found that 1702, or 0.9 per cent., of the people visited suffered from acute or chronic arthritis or had a history of such disease, and from these figures the calculation is made that some 34,000 persons suffer from arthritis in Finland. Incidentally it may be noted that the number suffering from pulmonary tuberculosis in Finland at the present time is about 45,000.

The geographical distribution of arthritis proved to be most uneven, its incidence ranging from a minimum of 0.3 to a maximum of 4.3 per cent. in the different communities studied. The farther west and north a community, the lower the arthritis-rate. Not one typical case of gout was found. The ratio of chronic to acute cases was as 2.2 to 1 (1177 to 525). Women were more subject to the disease than men in the ratio of 2.4 to 1, and when the disease was chronic and the nervous system involved (chorea) this sex inequality was 11 to 1. Acute arthritis had developed in most cases before the age of thirty, and there were very few such cases beginning after forty. On the other hand, new cases of chronic arthritis continued to develop throughout life. In more than half of all the acute and chronic cases, there was evidence of a heredito-familial character; and in a series of 771 that were very carefully studied, it was found that the disease could often be traced through several generations. In 62 of these 771 (about 8 per cent.) both husband and wife were found to suffer from arthritis. As for the disability entailed by this disease, women were found to be oftener, earlier, and for longer periods disabled than men.

Dr. Holsti and Dr. Rantasalo, whose note on this study appears in *Acta Medica Scandinavica* for March 20th, come to the conclusion that the frequent occurrence of several cases of acute and chronic arthritis in the same family points definitely to the existence of some inherent factor common to the genesis of arthritis. The element of contagion cannot be dismissed in view of the comparatively high incidence of this disease in both husband and wife. But on the other hand "there can be no doubt that other, non-infectious factors, inherited or acquired, in the form of some heredito-familial disposition to joint disease also enter into the pathogenesis." There is also the climatic factor as well as the unhealthy influence of bad housing and soil conditions. It was, perhaps, more than a coincidence that the incidence of arthritis was highest in an area in which endemic goitre was very common.

The authors of this note conclude with a brief outline of the measures they consider would be most effective against arthritis. Treatment, they find, has less prospect of success than prevention; and with regard to the latter they recommend the improvement of housing and soil conditions, the combating of endemic goitre, the weaning of dentists from the habit of retaining devitalised teeth in the jaws of their patients, and the removal of the tonsils of those persons who suffer repeatedly from attacks of sore-throat. It is to be hoped that the example set in

Finland of conducting an arthritis census will be followed in many other countries, for the information thus obtained is calculated to throw light on many aspects of this disease.

#### MILK IN A FEW WORDS

A MEMORANDUM entitled "The Nutritive Value of Milk," drawn up by the Ministry of Health's Advisory Committee on Nutrition, has just been published by H.M. Stationery Office (pp. 12, 3d.). It explains in simple terms the high value of milk as an article of food and mentions some of the investigations justifying the belief that the general health of the community, and especially of children, would be improved, and the incidence of disease diminished, if the present consumption of liquid milk, averaging about 0.4 pint per head per day, could be increased to about a pint. Children, it is stated, should receive 1-2 pints a day, and expectant and nursing mothers about 2 pints. Other adults, who need milk especially for the sake of its calcium and animal protein, should have at least half a pint daily. The memorandum speaks of the advantages of pasteurisation, and states that when milk is treated by heat there is little significant change in its nutritive properties, and such deficiencies as may be caused can readily be made good. It is therefore reasonable to assume that raw milk incorporated in other cooked articles of diet, such as bread and puddings, retains most of its nutritional properties. The report also calls attention to the degrees of nutritive value possessed by various milk products, especially separated milk.

#### THE MUNICIPAL YEAR BOOK

THE Minister of Health contributes a preface to the Year Book for 1936, and in commending it insists on the common enterprise in which the Ministry of Health and the local authorities are partners. One consideration especially he brings home to those who have the maintenance of our democratic institutions at heart and that is to encourage young people to study and appreciate their inheritance in the sphere of local government, so that the future will find people of integrity from all walks of life willing to shoulder its burdens and responsibilities. Of these burdens and responsibilities the Year Book gives accurate and comprehensive evidence. The volume this year contains two more sections than last although, fortunately, no more pages. Fully 80 per cent. of the volume, it is stated, has been rewritten. A list is given of conferences and meetings of associations in the coming year, and the whole book is worthy of the year which celebrates the centenary of the first Municipal Corporations Act in this country. The price of the Year Book is 30s. from the Municipal Journal Ltd., 3, Clements Inn, London, W.C.2.

#### NEW PREPARATIONS

STYPPVEN.—The value of the venom of Russell's viper as a hæmostatic has been established by Macfarlane and Burgess Barnett (*THE LANCET*, 1934, ii., 985). Under the name of Stypven the Wellcome Physiological Research Laboratories present Russell viper venom in convenient form. It is issued by Burroughs Wellcome and Co. (Snow Hill Buildings, London, E.C.1) in rubber-stoppered bottles (1 c.cm. or 5 c.cm.) accompanied by sealed ampoules of a solvent consisting of distilled water containing 0.5 per cent. phenol. A solution of the necessary concentration is readily prepared and in cases of hæmophilia the power of the venom to control external hæmorrhage allows of the performance of minor operations in reasonable safety. Apart from hæmophiliacs there are many patients who suffer from prolonged bleeding after extraction of teeth, and this may be relieved by local application of a pledget soaked in Stypven. It is also believed that this hæmostatic may prove valuable in general surgery and its use—perhaps in conjunction with adrenaline—is suggested as a means of stopping the

bleeding or oozing often encountered in operations on the nose and mouth.

**SKOL HEALING ANTISEPTIC** is an astringent liquid devised for application to injured tissues, over which it forms a non-greasy protective film. The manufacturers (Skol Products Ltd., Westminster, S.W.1) lay stress on its unusual light-filtration properties; it cuts out "irritating and destructive ultra-violet rays up to 3700 Angstrom units." Good results are claimed in the treatment of burns, and except in severe second-degree burns its application is said to render dressings unnecessary. Its use is also advised in the treatment of bedsores, cuts, chilblains, stings, and various skin conditions, including some forms of eczema and varicose ulceration; it is further recommended, diluted with water, as a mouth-wash, gargle, and nasal antiseptic. The formula given is: extract of galls, 5.00; methyl-propyl phenol hexahydride, 0.25; phenyl hydrate, 0.50; glycerin, 3.00; ortho-oxy-benzoic acid, 1.00; alcohol and water, 90.25.

**ENTORAL** is a vaccine given by mouth as a protection against colds and other respiratory infections. The makers, Messrs. Eli Lilly and Company of Indianapolis (2, Dean-street, London, W.1), point out that although the common cold may be primarily caused by a filtrable virus its effects are largely due to associated organisms, including pneumococci, influenza bacilli and streptococci. They quote evidence that oral administration of vaccines will produce appropriate antibodies, and they attribute the peculiar success of Entoral Lilly to its preparation from strains with a high content of heterophile antigens. Such antigens evoke immune bodies which hemolyse sheep corpuscles, and the observations of Rockwell, van Kirk, and Powell (Jour. of Immunol., 1935, xxviii., 475) suggest that after vaccination there is a definite correlation between the heterophile antibody content and the immunity established. These authors report that the use of an oral vaccine of pneumococci and streptococci was followed by a decrease of 57 per cent. in the annual incidence of colds among 500 treated persons; whereas 536 controls showed a decrease of only 12 per cent. for the same year. The best results were obtained in those most susceptible. Entoral Lilly is provided in capsules containing 25,000 million pneumococci, 5000 million *Hemophilus influenzae*, 15,000 million streptococci, and 5000 million *Micrococcus catarrhalis*. The dose recommended is one capsule daily for seven days, taken with cold water an hour before breakfast; two capsules are then taken weekly throughout the season. Usually there is nasal stuffiness or slight catarrh after the first dose or two, and very occasionally there is gastro-intestinal distress; but "reactions have not been particularly noticeable."

The British Drug Houses Ltd. have issued a short and informative account of the functions and clinical use of ovarian and gonadotropic hormones, with special reference to their own preparations GONAN, ESTROFORM, ESTROFORM B, and PROGESTIN B.D.H. It may be obtained from them at Graham-street, City-road, London, N.1.

We are informed that **RECRECAL** is now manufactured in this country and distributed by Messrs. Coates and Cooper Ltd., 94, Clerkenwell-road, E.C.1. It is a preparation of sodium dihydro-ortho-phosphate and its use is based on German work, dating from 1921, which led to the conclusion that muscular and mental output can be increased by regular administration of phosphoric acid in this form. Recreocal is also said to be useful in shortening the course of infectious diseases, in overcoming debility and exhaustion (especially in children), and in promoting the healing of wounds.

**CHICKEN-POX AND HERPES ZOSTER.**—Dr. A. G. P. HARDWICK (Newquay, Cornwall) writes: "A case

of academic interest has just occurred in my practice—that of a man, 76 years old, who contracted a severe attack of chicken-pox from a case of facial herpes zoster. On March 3rd I saw a man, aged 60, suffering from severe facial shingles. On March 5th, 6th, and 7th he was visited for two minutes each day by his next door neighbour. On March 20th I was called to see this neighbour, with a temperature of 103° F. and a profuse and typical rash of chicken-pox. There could have been no other chance of contracting the disease."

**CORRIGENDA: LARGE DOSES OF ATROPINE.**—An annotation in our last issue (p. 908) described experiments in Rumania in which atropine was given to patients in gradually increasing doses, to which they became tolerant. We stated that the doses mentioned were injected, but actually they were given *by mouth*.

The note about the work and needs of an ophthalmic hospital in our last issue (p. 910) referred to the Royal London Ophthalmic Hospital (Moorfields).

## Appointments

**PEGGETTER, G. Y.,** M.S. Durh., F.R.C.S. Edg., has been appointed First Assistant in the Department of Surgery at the British Postgraduate Medical School, London.

**JONES, E. R.,** M.D. Liverp., D.P.H., Assistant Pathologist in the Kent County Council Laboratories.

**MANSIE, J. W.,** M.R.C.S., L.D.S. R.C.S. Eng., Dental Surgeon to the Evelina Hospital for Sick Children, London.

Certifying Surgeons under the Factory and Workshop Acts: **Dr. E. A. R. EVANS** (Wrexham District, Denbigh); **Dr. T. V. FITZPATRICK** (Broughton District, Hants).

*Institute of Medical Psychology.*—The following appointments are announced:—

**ALLEN, CLIFFORD, M.D.,** M.R.C.P. Lond., D.P.M., Psychologist; **DOHERTY, WINIFRED, M.B. Leeds, D.P.H., D.T.M.,** Psychologist; **HAMILTON-PEARSON, E. A., M.B. Aberd.,** Psychotherapist; **HUTCHISON, ALICE, M.D. Edin., M.R.C.P. Lond.,** Psychotherapist; **MILLS, HERMIA, M.B. Lond.,** Psychotherapist; and **THOMS, AMY, M.D. St. And., M.R.C.P. Lond.,** Psychotherapist.

## Births, Marriages, and Deaths

### BIRTHS

**BAWTREE.**—On April 14th, at Tunbridge Wells, the wife of D. W. Bawtree, F.R.C.S. Edin., of a son.

**BONNER-MORGAN.**—On April 17th, at Lancaster-road, Hampstead, the wife of Dr. W. R. Bonner-Morgan, of a son.

**DINGWALL.**—On April 13th, at a nursing-home, the wife of Surg. Lt. R. G. Dingwall, M.B. Aberd., R.N., of a son.

**GARROD.**—On April 14th, at Harpenden, the wife of Lawrence P. Garrod, M.D. Camb., of a son.

**GREEN.**—On April 16th, the wife of Dr. Leslie E. Green, Eastleigh, Hants, of a son.

**LAWSON.**—On April 15th, at Cambridge, the wife of W. A. D. Lawson, M.D. Leeds, Whittlesey, near Peterborough, of a daughter.

**SAMMONS.**—On April 11th, at Kingswood, Bristol, the wife of Dr. R. A. Sammons, of a son.

**SHELDON.**—On April 13th, at Sutherland-avenue, W., the wife of Dr. Colin Sheldon, of Reigate, Surrey, of a son.

**TAYLOR.**—On April 16th, at Purley, the wife of Dr. C. E. Taylor, of a son.

### MARRIAGES

**PARKES—JAMES.**—On April 16th, at St. Thomas's Church, Douglas, I.O.M., Richard Quine Parkes, M.B., B.Chir. Camb., to Marjorie Whitehead, elder daughter of Mr. J. J. James of Douglas.

### DEATHS

**BROOK.**—On April 14th, Francis William Brook, M.R.C.S. Eng., of Harley-street, aged 59.

**HAMBLIN SMITH.**—On April 15th, at Oxford, Maurice Hamblin Smith, M.D. Durh., late of H.M. Prison Service.

**HUSBANDS.**—On April 15th, Harold Wessen Husbands, M.R.C.S. Eng., of "Fairlight," Babbacombe, Torquay (formerly of Taunton).

**LANE.**—On April 15th, in London, Major George Lane (late R.A.M.C., S.R., and Colonial Medical Service), previously of Rowlands Castle, Hants, in his 68th year.

**OSBORN.**—On April 16th, at Datchet, Bucks, Samuel Osborn, F.R.C.S. Eng., J.P., Knight of Grace, Order of St. John of Jerusalem.

**SHELDON.**—On April 15th, at Chepstow Villas, W., Walter Sir Sheldon, M.R.C.S. Eng., in his 60th year.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## ADDRESSES AND ORIGINAL ARTICLES

THE PREVENTION OF CANCER<sup>1</sup>

By W. SAMPSON HANDLEY, M.S. Lond., F.R.C.S. Eng.  
SENIOR SURGEON TO THE MIDDLESEX HOSPITAL

It is quite possible that a medical or systemic cure of cancer will be discovered before the nature of the neoplastic process is fully understood, for the use of quinine and mercury, in malaria and syphilis respectively, preceded the discovery of the organisms of these diseases. On the other hand the technique of prevention of a disease would appear more closely dependent upon knowledge of its causation. The prevention of malaria waited upon that knowledge of the life-history of the malaria parasite which Laveran, Manson, and Ross supplied. I believe that a general conception of the origin of the cancer process, founded upon observed facts, can now be arrived at, however obscure the intimate nature of the process may remain. If so, the prevention of the disease can be approached in a more hopeful spirit, and my choice of subject may be justified.

## Theories of the Causation of Cancer

Any theory of the causation of cancer must cover and unify an extraordinary and miscellaneous range of observed facts. The late Prof. Archibald Leitch in 1927 collected these facts together without deducing from them any theory. He pointed to Pott's observation that chimney-sweeps were especially liable to cancer of the scrotum as the first gleam of light on the origin of cancer—showing it to be a disease of local and not of constitutional origin. Pott noted that the disease slowly and imperceptibly evolved from a simple wart resulting from prolonged contact of soot with the skin. It was Leitch himself who showed that the soot did not act mechanically, and that its admixture with the sebaceous secretion of the scrotum was necessary to activate it. The fatty secretion dissolved out of the soot some active cancerogenic agent in minute quantity.

In 1771 Volkmann described cancer of the anus and scrotum in workmen employed in lignite distillation plants and due to the crude distillates of tar or paraffin. Some years ago Alexander Scott described the cancers occurring in Scotland in workmen exposed to shale-distillation products. Crude petroleum and some refined oils also have been found to cause cancer. A. H. Southam and S. R. Wilson found that cotton spinners, exposed to a spray of mineral oil from the spindles, suffer from cancer of the scrotum. Workers in hot tar are liable to cancer on the exposed forearms and also on the scrotum. The chewing of betel-nut mixed with lime often produces cancer inside the cheek and upon the gums.

Reviewing such facts as these there is little cause for surprise if the inference was drawn that cancer is due to direct local chemical irritation of the epithelium. Soon however it appeared that physical irritants might be substituted for chemical irritants without any alteration in the final result. Theodore Maxwell in Kashmir noted that repeated burns of the skin, resulting from the wearing under the robes of the kangri basket containing hot charcoal, might eventually lead to cancer. Twelve years after the discovery of X rays the first X ray cancer was evolved.

Prolonged exposure to radium produced the same result. G. M. Findlay has produced papilloma and carcinoma in white rats by exposing the ear to ultra-violet light. Rodent ulcer and epithelioma of the skin are especially frequent in Queensland where a white race unprotected by pigment is exposed to a tropical sun.

The radiation cancers were brought under the fold of the irritation theory of cancer by a simple expedient. It was admitted that the irritation might be chemical or physical.

## ARSENIC AND ANILINE CANCER

About 1887 Jonathan Hutchinson drew attention to a form of cancer arising in patches of psoriasis in patients who had taken arsenic therapeutically for long periods. The same thing occurs in arsenic workers in Styria, and Leitch observed cases in men engaged in the manufacture of sheep-dip and weed killer. In arsenic cancers the metal inhaled or swallowed is excreted by the skin, and the growths may be widespread and multiple. Workers in aniline dyes are subject to cancer of the bladder, probably owing to the excretion of ingested dye-products in the urine.

There was no difficulty in applying the irritation theory to cases where the irritant acted during its excretion upon the excretory organs. Certain difficulties however showed themselves, particularly the fact that the cancer might show itself many years after the patient's last contact with the irritant, and that some violent irritants such as mustard oil have no cancer-producing power. It became necessary to define an irritant as any substance or agent which can induce cancer. It thus became clearer than ever that cancer is due to chronic irritation.

## LUPUS AND SYPHILIS CANCER

Many years after an area of lupus has completely healed, and apart from any therapeutic treatment, it may become the seat of squamous-celled carcinoma. A tongue which has suffered from mucous tubercles and syphilitic glossitis in the secondary stage of syphilis is likely in later life to be affected by chronic glossitis and epithelioma. The irritation theory was accordingly modified by including certain bacteria in the list of cancer-producing irritants, and later certain parasitic worms were added to it, following Fibiger's discovery that cancer could be produced in underfed rats by feeding them with cockroaches infected with gongylonema, a minute parasitic worm. The ova of ankylostoma duodenale invading the mucosa of the bladder were found to cause cancer of that organ. Peyton Rous and W. E. Gye found that a filter-passing virus was the cause of sarcoma in fowls. J. B. Murphy, of the Rockefeller Institute, maintained that the supposed virus was of the nature of a ferment. Recently a virus has been incriminated by R. E. Shope as the cause of an infective papilloma in rabbits which may become malignant, but this is the only instance in mammals where substantial evidence for a virus as a possible cancer agent has been produced.

## LYMPH STASIS AND CANCER

In such a tangle of miscellaneous causes it is fair to assume that links in the chain of causation are missing, and that as the final result—cancer, is approached unity of causation might be detected. I believe that in lymph stasis and its physiological

<sup>1</sup> Being the seventeenth Mitchell Banks Memorial Lecture delivered at the University of Liverpool on Nov. 21st, 1935.

consequences I have found the single immediate cause of cancer. All the various cancerogenic agents have I believe this quality in common that they can produce lymphangitis and consequent lymphatic obstruction. I have been able to demonstrate the presence of lymphatic obliteration and consequent lymph stasis in precancerous areas due to the ravages of syphilis, tubercle, X rays, or radium, or resulting from the chronic lymph stasis of chronic mastitis. No single organism or virus is specifically and exclusively associated with the production of cancer. Any physical or chemical agent, any organism or mixture of organisms, able to cause lymphangitis, may set going a process which in ten, twenty, or forty years may eventuate in malignancy.

#### The Pathology of Lupus Cancer

For the sake of brevity I desire to concentrate attention upon one particular form of cancer, lupus cancer, in which the stages of the process which leads to cancer are easily demonstrable. I would first insist that tubercle bacilli may have disappeared for many years from the original area of lupus before cancer appears in it. A sound scar with a few papillomata upon it may be the only residue of the original disease. The epithelium appears healthy and there is nothing to indicate that the tuberculous poison has produced any change in it. In the early stage of lupus, the stage of active extension and ulceration, before repair has begun, the epithelium seems entirely passive. It quietly disappears as the lupus nodules undermine it. When repair begins the epithelium spreads over the new granulation tissue in a normal way. Sometimes the lupus process is not intense enough to cause ulceration. It then gives rise to papillomatous elevations of the skin. A section through the growing edge of such an area of papillary lupus—a section taken outside its visible margin—shows with crystal clearness not only the nature of the lupoid process, but also the nature and mode of origin of papilloma. Just as a lacteal is the central structure of an intestinal villus, a capillary lymphatic end-sac is the central structure of a villus of the skin. It can be seen that over a zone about  $\frac{1}{2}$  inch wide outside the apparent edge of the lupus area the papillary lymphatics are blocked by proliferation of their endothelium.

Evidently lupus is essentially a tuberculous lymphangitis of the skin lymphatics. Furthermore it can be seen that the blocking of the central lymphatic has upset the hydrostatic arrangements of the papilla. The tissue fluid can no longer flow freely out of it and the papilla begins to swell and to elongate. From the edge of the specimen back towards the centre of the lupus area a gradual elongation of the skin papillæ up to ten times their normal length can be traced. Their connective tissue receives from this lymph congestion a powerful stimulus to proliferation in which at a later date the epithelium shares. How powerful is the nutritive stimulus of lymphatic obstruction upon the tissues subjected to it is well seen on a large scale in the huge legs of elephantiasis. Wherever a papilloma is found it may be presumed, and it can frequently be demonstrated, that this process of obliterative lymphangitis has previously affected the lymphatics of the papilla. It is a fact of the highest significance that nearly every form of cancer affecting squamous celled, transitional or columnar-celled surfaces is preceded by papilloma. In the case of glandular mucous membranes such as that of the stomach, cancer is preceded by adenoma, which is also a manifestation of lymphatic obstruction. The close and almost

universal association of papilloma and adenoma with cancer shows in my opinion that lymphatic obstruction is a precursor of cancer which may fairly be described as its cause.

It is easy to understand how the physical stimuli which cause cancer are able to cause lymphangitis and lymphatic obstruction. In X ray dermatitis the obliteration of some lymphatics and the dilatation of others are easy to demonstrate. But at first sight tar-cancer seems to be a difficulty. Here the tar is applied directly to the epithelium which subsequently becomes cancerous and direct irritation seems proved. But Ludwig Kreyberg has studied the changes in the mouse, produced by tar-painting, and has shown that the initial change is an infiltration of the subepithelial tissues by polymorphic leucocytes. The primary response to tar-painting occurs in the connective tissue and its appearances are those of an acute lymphangitis.

#### CHRONIC MASTITIS

A study of the physiology of the breast shows that nature's method of inducing proliferation is to pour out an excess of lymph into the tissue interspaces, and provides further evidence of the important part played by lymph stasis in physiology and in the genesis of cancer. The recurrent monthly physiological lymph stasis which occurs in the breast temporarily stimulates the proliferation of all its tissues. If lymphatic return from the breast is hindered by local areas of lymph obstruction, probably due in most cases to casual and unnoticed infections of one or more breast-ducts where they open upon the nipple, the stimulus of lymph congestion instead of being periodic becomes permanent. The lobe whose duct has thus been infected is unable to empty itself of lymph, and receives a permanent stimulus to proliferation. The lymphatics are blocked by proliferation of their own endothelium. The ducts are surrounded by a sheath of adventitious fibrous tissue due to proliferation and blocking of the periductal lymphatics. Papillomata appear within them as the nutritional stimulus begins to affect the epithelium, and finally carcinoma may supervene.

It is the fashion to ascribe the various diseases which affect the breast to endocrine disorders, and there is of course no doubt that the breast is under endocrine government. But morbid conditions such as chronic mastitis affecting single and separate lobes of the breast, and sparing other lobes of the same breast, cannot be accounted for by general endocrine influence. A local factor must be present, and that local factor is permanent lymph stasis. The various steps which lead from lymph stasis through chronic mastitis to cancer may be easily demonstrated histologically. Space forbids me to discuss other forms of carcinoma or to discuss congenital moles in which developmental defects of the lymphatic system lead to local areas of lymphatic obstruction and papillomatous hypertrophy, and sometimes to carcinoma or sarcoma.

#### Prevention in the Light of Ætiology

If the lymph-stasis theory of cancer is valid the simple recipe for the prevention of cancer is to maintain the lymphatic circulation throughout the body in a state of high activity. If, as is often stated, though without conclusive evidence, cancer is relatively infrequent in wild animals, this may well be due to the superior vigour of their lymphatic circulation, the result of an active life. Even in local areas of lymph stasis a sufficient minimum

flow may thus be secured to avert a threatened carcinoma. Civilised man may well take the hint, remembering that as E. H. Starling showed a resting limb produces hardly any lymph. Civilised man is apt to overstrain his glandular mechanisms, especially those of digestion, while at the same time he allows his muscles to fall into disuse. Glandular secretion increases the production of lymph without doing anything to promote the lymphatic circulation. Muscular exercise on the contrary brings into play all the forces which maintain the lymphatic circulation—the pulsation of adjoining arteries, the massage action of muscular contraction and of bodily movements, and the aspiration effects of deep respiration. Thus regular exercise and moderation in eating are likely to stave off cancer, but a heavier stress must be laid on the avoidance of infections and their prompt treatment, for the small local areas of lymph block in which cancer arises are most often due to bacterial infections, severe or slight. In this connexion dental infection requires special stress, for as F. St. J. Steadman<sup>2</sup> showed, cancer of a dentally clean mouth is a rarity.

#### PREVENTION OF CANCER IN PRECANCEROUS AREAS

Sometimes the best method of dealing with precancerous areas is to excise them. The enlarging mole, or the papillomatous area in chronic glossitis, may thus be dealt with. But the method is sometimes impossible and never popular.

*Irradiation of Precancerous Areas.*—It would appear quite feasible to administer to precancerous areas a sufficient dose of radiation to depress the activity of the potentially cancerous epithelium. In this connexion I will only refer to one variety of cancer, and give *prima facie* evidence that a short course of deep X rays will avert cancer in precancerous breasts.

I may remind you that in the year 1900 at the Pathological Society of London the late F. T. Paul<sup>3</sup> of this city first drew attention to the association between chronic mastitis and tumour formation. Though the question continues to arouse controversy there is in my mind no doubt of the intimate connexion between chronic mastitis and subsequent cancer.

In 1910 I advocated<sup>4</sup> the X ray treatment of chronic mastitis, which has since been widely adopted. The sector-shaped indurations of chronic mastitis frequently soften or disappear after three half-pastel doses of X rays. At that early period the modern hard X ray was unknown, and among several hundred cases of chronic mastitis treated in this way several developed cancer. Of late years I have continued to use the method, but have advised the high potential short wave X ray of 180,000 volts. Several hundred cases have been treated for me in this way by Dr. Russell Reynolds, Dr. Douglas Webster, and other radiologists, and in no single case has cancer supervened in the breast treated. When a breast has suffered from chronic mastitis and cancer, the other breast is likely in the course of years to follow the same course. I will give an instance.

Five years ago I operated upon a nurse with cancer of the right breast. Three years ago I found a mastitic thickening in the other breast and urged either mastectomy or X ray treatment for this breast. The patient rejected my advice, and was only seen again recently, when she had a hopeless carcinoma originating in the mastitic area of the remaining breast—not a recurrence but a second primary growth.

In another case I tapped a cyst in the left breast three years ago. Three doses of deep X rays were applied to the breast. The patient was seen again recently. The left breast was normal, but the right breast to which no X rays had been applied had to be removed for a suspicious induration which showed cystic changes and areas of papillomatous proliferation, undoubtedly precancerous, in the ducts (see Figure). In this case X rays appear to have arrested the morbid evolution in the breast which was primarily affected. The second or control breast, at first the healthier breast, continued to evolve towards carcinoma.

Precancerous changes in the untreated breast. The other breast, which had given earlier evidence of similar tendencies, remained normal three years after X ray treatment.

I could adduce other cases tending to show the preventive action of X rays upon precancerous breasts. The problem is one of great importance, and could be definitely settled if 1000 women would permit one breast to be irradiated at the age of forty, the other breast remaining untreated as a control. A complete follow-up in each case would of course be necessary. A preventive course of X rays to both breasts is at any rate harmless, and should certainly be given when the breast has done its work to all women with a strong family history of cancer, or suffering from chronic mastitis.

#### PENILE CANCER: PREPUTIOTOMY

Carcinoma of the penis is not a common, but not a very rare form of the disease. At the Mayo Clinic 195 cases were seen from 1907 to 1932; about one case in every 300 of male cancer. The institution of circumcision has provided for the Jews complete protection against penile carcinoma. The origin of the operation is lost in the mists of antiquity but it was practised by the Egyptians of the predynastic era, and the oldest known mummy, that of Ra-Nefer in the R.C.S. Museum, presents evidence of circumcision. A simpler operation would produce the same protective result. If the dorsum of the prepuce is slit up as far as the glans, and a stitch if necessary inserted at the upper end of the incision, within a few years time, owing to the gradual retraction of the lateral flaps of the prepuce, the result will be indistinguishable from that of circumcision. If performed just after birth the little operation can be done without an anaesthetic.

<sup>1</sup> British Dental Journal, 1923, xlv., 1325.

<sup>2</sup> Trans. Path. Soc., London, 1900, lli., 30.

<sup>4</sup> Practitioner, 1910, lxxxiv., 463.

In phimosi a delicate mucous membrane is exposed for life to the attack of a mixed bacterial flora living under complete shelter, and also to the chemical action of decomposing secretions. Recurrent attacks of lymphangitis of the glans, and the resulting lymphatic stasis, provide the basis for papilloma and cancer. S. K. Ngai, in reporting on 107 cases of carcinoma of the penis in China,<sup>5</sup> found that of 88 patients who made a positive statement on the matter 87 had had phimosi. Carcinoma of the penis is frequent among Chinese farmers and coolies, rare in the educated classes. That the Jewish immunity is not racial is indicated by Wolbarst's case occurring in an uncircumcised Jew, while there is no case in the literature occurring in a circumcised Jew.

PHIMOSIS AND UTERINE CARCINOMA

There is evidence that the existence of phimosi, or in its absence carelessness as to subpreputial hygiene and cleanliness, is a menace even more serious to the female sex than to the sex in which they originate. Briefly stated the evidence is this, that though certain forms of cancer—of the liver, the breast, and the rectum for instance—affect Jews more frequently than non-Jews, Jewish women show a much smaller liability to carcinoma of the cervix. In Amsterdam the non-Jewish inhabitants were found by Hoffman to show an incidence to cervix cancer of ten per 100,000, while the corresponding figure for Jewish women was less than four.

Cancer in Amsterdam 1919-29 (Hoffman)

	Catholics. Jews.			Catholics. Jews.	
	(per 100,000)			(per 100,000)	
Stomach	47.9	32.9	Breast	9.32	11.3
Liver and gall-bladder	13.21	17.16	Esophagus	9.51	3.63
Intestines	12.66	9.49	Rectum	6.48	8.37
Uterus	10.19	3.6	Lung	2.66	3.39

Maurice Sorsby comments<sup>6</sup> on the relative freedom of Jewish women from cancer of the uterus. Vineberg, in the out-patient department of the Mount Sinai Hospital of New York, observed among 19,000 patients, of whom 95 per cent. were Jewish, only 18 cases of uterine cancer and nine of these were in non-Jewish women. Thus the incidence among the Jewish women was only one-eighteenth of that among non-Jewish. Two other investigations by Rubin at the same hospital for other years gave incidence ratios of 1 to 7½ and 1 to 15 for Jews and non-Jews. Similar evidence is quoted by Sorsby from the Mayo Clinic. In every thousand non-Jewish patients seen at the Mayo Clinic six have carcinoma of the cervix; in every thousand Jewish patients only one has carcinoma of the cervix. Similar evidence is quoted by Sorsby from Paris, Budapest, Munich, Amsterdam, and Montreal. He concludes: "All the available evidence is therefore unanimous in pointing to a definitely lower incidence of uterine cancer among Jewish women." He believes that the hygienic ritual imposed on women by the Mosaic law accounts for their immunity, but the explanation seems unconvincing. The cervix exists normally under the same optimal conditions for bacterial life which are found under the phimotic prepuce. It is not surprising if marital infection with the subpreputial flora may lead to cervical cancer in the course of twenty or thirty years, just as in the male it leads to penile cancer. Immunity to penile carci-

noma and partial immunity to cervix cancer are not constitutional peculiarities of the Jewish race. There is another race which enjoys the same privileges, and that race also practises circumcision.

During a brief visit to Fiji in 1927, my attention was drawn to the occurrence of penile cancer in the Indian inhabitants originally imported from India, and to its absence among the aboriginal Fijians. The two races live side by side without mixing and the islands contain about 90,000 Fijians and 70,000 Indians. The Fijians, but not the Indians, practise circumcision at puberty. I endeavoured to find out the relative liability of the women of the two races to cervix cancer.

A search through the careful reports of the Colonial War Memorial Hospital at Suva, Fiji, shows that during the eight years, 1925-32 inclusive, three cases of cervical carcinoma in Fijians were admitted, and 26 cases in Indian women. Thus the smaller of the two population groups, the one not practising circumcision, shows an incidence of cervix cancer upon its women more than eight times greater than the incidence of the disease upon women of the other or circumcised nation. The total number of hospital cases of malignant disease of all kinds in Indians was 97 as compared with 61 in Fijians.

The freedom of the Fijian race from cervix cancer is therefore not due to any racial immunity to cancer, nor can it be explained as illusory and due to reluctance to seek hospital treatment. It must be attributed to the protection which the hygienic operation of circumcision affords against mixed bacterial infections of the cervix during coition. It is customary to ascribe cervix cancer to trauma of the cervix during parturition, but if this were the case both races should be affected equally.

PUERPERAL SEPSIS AND THE MALE

If chronic mixed infections are mainly responsible for cervical carcinoma, it is pertinent to inquire whether the obstinate persistence of high puerperal mortality, in spite of the vigorous campaign directed against it by our health authorities, may have a similar origin. The maternal death-rate per 1000 live and stillbirths, which in 1928 was 1.72, actually rose in 1933 to 1.75. The rise, otherwise difficult to explain in this aseptic era, is intelligible if, as I suggest, an important aetiological factor has been ignored. Educational insistence on strict personal hygiene for the man would be slow and uncertain in its action. Insistence on universal preputiotomy might very well prove to be a controlling factor for this particularly cruel and obstinate scourge of our national life.

In a discussion on Puerperal Blood Infections at the Fifth British Congress of Obstetrics and Gynaecology, held in London in 1925, the late Prof. W. Blair-Bell<sup>7</sup> expressed the view that coitus shortly before parturition might be an important factor in puerperal sepsis. In 20 per cent. of lying-in patients who gave a history of recent coitus, hæmolytic streptococci were found in the vagina.

I have endeavoured to obtain evidence of the relative incidence of puerperal pyrexia in Jewish and non-Jewish women. The Ministry of Health were unable to find for me any study of the subject. It urgently needs investigation. The relations of phimosi to puerperal sepsis should also be studied.

The subject has reached a stage when authoritative advice upon it should be given by the Ministry of Health, or by such a responsible body as the British Empire Cancer Campaign. The question which King Edward VII. asked about tubercle, "If preventable

<sup>5</sup> Amer. Jour. of Cancer, 1933, xix., 259.  
<sup>6</sup> Cancer and Race, London, 1931.

<sup>7</sup> Jour. Obst. and Gyn., 1925, xxxii., 243.

why not prevented?" is equally pertinent to the forms of carcinoma we have just considered.

#### DENTAL HYGIENE

The British Dental Association urges that dental benefit should be made a covenanted benefit under the National Health Insurance Act. The governing body of the British Medical Association resolved in 1928 that "the establishment of periodical medical and dental examinations of all persons insured under the National Health Insurance Acts is urgently called for as an economic proposition, having regard to the return so to be obtained in health and productive efficiency." But examination without treatment is not enough. The task that must be imposed on the dental profession is to maintain the oral hygiene of eighteen million insured workers and their dependants, a total of about forty million persons, most of whom at present receive no attention beyond occasional dental extraction. At a reasonable estimate this means forty million hours' work a year, or eight hours additional work each week-day throughout the year for every person on the Dental Register. The financial aspects of the question are no less alarming, for even at a capitation fee of 12s. 6d. per annum, the lower of two figures suggested by the British Dental Association, the cost would be twenty-five million pounds a year.

It is clear that the scheme can only be introduced by degrees, and that it must be accompanied by a large increase in the numbers of the dental profession, unless some of the work is delegated under supervision to partially trained persons, a plan which has been successfully adopted in New Zealand with the approval of the local dental profession. It is equally clear that self-help must be invoked. A weekly voluntary contribution of twopence from each beneficiary, to which Parliament or the approved society might be asked to add another penny, would launch the scheme, and it would gradually grow as the people came to realise its advantages.

Until dental hygiene is secured there is little hope for any further diminution in cancer of the mouth, tongue, pharynx, œsophagus, and stomach, and gastric and duodenal ulcers will continue to wreck many lives.

#### A Practical Programme

Let me now sum up my simple practical programme for the prevention of cancer: Preputiomy on all male infants at birth for the abolition of penile cancer, the diminution of cancer of the cervix in women to one-sixth of its present incidence, and a probable incidental lowering of puerperal mortality. Instruction of men in the importance of personal hygiene. A short prophylactic course of deep X rays to the breasts in all cases of chronic mastitis, especially if cystic, for the prevention of breast cancer. Dental treatment of the people on a national basis for the prevention of cancer of the mouth and alimentary canal.

**CHESTER ROYAL INFIRMARY.**—It was stated at the annual meeting of this hospital that it treated one person out of six of the local population during the last year. Ordinary income almost equals ordinary expenditure, but more income will be needed, since the full cost of the additional nurses engaged on completion of the nurses' home extensions has not yet been felt. The extension of the out-patient department is becoming urgent. The establishment of a preliminary training school has been approved and probationers will be admitted for courses of six weeks.

## ON THE POSSIBLE RÔLE OF THE ANTERIOR PITUITARY IN HUMAN DIABETES

BY O. L. V. DE WESSELOW, D.M. Oxon.,

AN increasing appreciation of the factors involved in the control of the blood-sugar has again opened up the whole question of the aetiology of "diabetes." We may, perhaps, formulate the orthodox position somewhat as follows. After exclusion of certain well-recognised types of glycosuria, such as those associated with thyrotoxicosis, hyperadrenalæmia, and some pituitary lesions, the remainder of our patients who exhibit hyperglycæmia and glycosuria are assumed to form a more or less homogeneous group, and to be suffering from varying degrees of insulin deficiency. Inability to store and utilise carbohydrate is to be ascribed to this lack of insulin, with resulting hyperglycæmia, glycosuria, and ketonuria; their low respiratory quotient (R.Q.), both fasting and after ingestion of carbohydrate, appears to afford contributory evidence of a lack of carbohydrate oxidation. This conception of insulin inadequacy has been enormously strengthened by the success of insulin therapy.

Although insulin has made it possible to restore the diabetic to a normal state of carbohydrate metabolism the mode of action of this hormone has for long remained obscure despite the most searching inquiries. During the last few years, however, the importance of so-called diabetogenic factors of pituitary origin, resulting in a disturbance of the normal regulation of carbohydrate metabolism, has been established, mainly by the work of Houssay and his colleagues.<sup>1</sup> For details of this work the reader is referred to the recent publications of Collip.<sup>2</sup> Houssay was able to show, first in the toad and subsequently in the dog, that removal of the anterior lobe of the pituitary gland in the depancreatized animal is followed by amelioration of the diabetic symptoms: hyperglycæmia, glycosuria, and ketonuria are diminished, and there is a gradual rise in the R.Q. and a fall in the urinary D:N ratio (Soskin<sup>3</sup>). By injection of pituitary substance into these depancreatized-hypophysectomized animals the improvement in the diabetic condition was abolished. It appeared, therefore, that the symptoms arising from pancreatectomy are to some extent of pituitary origin. In further confirmation of this diabetogenic action of the pituitary, Houssay and his co-workers<sup>4</sup> showed that injections of anterior pituitary extracts into the normal toad, dog, and other animals lead to hyperglycæmia, glycosuria, and ketonuria. This work is of especial interest in view of the association of acromegaly and glycosuria and, indeed, it had been shown by Borchardt,<sup>5</sup> as early as 1908, that injections of extracts of bovine pituitary glands into rabbits result in hyperglycæmia and glycosuria.

In view of these striking experimental results in animals it is natural that the question of the significance of the pituitary in relation to human diabetes should arise: do any of the metabolic disturbances which we have hitherto regarded as due to insulin

deficiency in fact arise from a disturbance of the function of the anterior pituitary? The glycosuria which is so frequent in acromegaly lends support to the view that glycosuria in man may result from pituitary dysfunction; glycosuria is also a feature of the Cushing syndrome. There is, moreover, another group of cases showing disordered carbohydrate metabolism in which the possible rôle of the pituitary cannot be ignored; we refer to those patients, usually past middle age and obese, in whom glycosuria and hyperglycæmia, but little ketonuria, are present, and in whom the subjective symptoms are relatively mild and the course of the disease protracted. In such patients the glycosuria is not infrequently discovered accidentally, attention being first drawn to its presence in the female by the appearance of vulvitis; apart from this the often gross glycosuria does not appear to affect the patient's well-being. This class of patient differs materially from the typical young diabetic, in whom the disease is accompanied by marked ketosis, wasting, and if untreated a rapid progress to coma and death.

In the present unsatisfactory state of our knowledge these two classes of patients, in whom the course and prognosis of the condition are so widely different, are perforce included in a single group under the head of "diabetes." It is at least possible that the hyperglycæmia and glycosuria characteristic of both groups constitute a purely superficial resemblance and that the underlying causes of the condition are as different as those in the depancreatised animal and in the animal receiving anterior pituitary substance by injection.

#### EXPERIMENTAL

With the object of obtaining some insight into this problem we have studied the effect of a preceding injection of "diabetic" blood as compared with "normal" blood on the response of the rabbit to insulin.

We have used immature male rabbits of about 1 kg. body-weight, maintained on a diet of cabbage, oats, and bran. The animals were starved for 18 hours before the experiment. Three hours before the response to insulin was determined, 10 c.cm. of the plasma to be examined was injected subcutaneously into the animal. The plasma was obtained from heparinised blood, spun out immediately after withdrawal and preserved in a refrigerator, in most cases over-night; in a few instances the plasma was injected within one hour of bleeding the patient. Three hours after injection of the plasma the animal received 0.2 unit of commercial insulin (Boots) into the marginal vein of the ear. The blood-sugar was estimated by MacLean's method on 0.1 c.cm. of blood withdrawn from an ear vein before and at quarter-hour intervals, for one hour after injection of the insulin. Two or three days before testing the effect of plasma, an insulin curve was obtained on every animal without preliminary injection of plasma. Young animals were employed with a view to obtaining a larger dose of plasma per unit of body-weight, and in the hope that they would prove more sensitive as test-objects. With very few exceptions a fresh animal was employed for each plasma tested.

The patients whom we have studied may be divided into four groups and the blood-sugar curves obtained in each group, together with the corresponding control curves, are averaged and are shown in Figs. 1-4. These groups were as follows:—

(i.).—Controls. 9 middle-aged subjects; 4 males and 5 females, suffering from various chronic diseases but with no disturbance of carbohydrate metabolism and on an ordinary mixed diet.

(ii.).—7 young diabetic patients; 3 males and 4 females, of whom 6 were under thirty, while in the remaining case the disease had appeared at the age of thirty-six. All but 2 of these had been receiving insulin for some time.

(iii.).—16 elderly diabetic patients; 1 male and 15 females, all but 2 of whom were between the ages of fifty and seventy-five. With the exception of 1 female, the blood pressures of these subjects were abnormally high and the great majority were overweight. 3 only were receiving insulin, the remainder being dietetically treated.

(iv.).—6 subjects from Group III. whose plasma appeared definitely to affect the blood-sugar response to insulin; the average of ten curves obtained from these individuals is given.

#### RESULTS

Inspection of the curves shows that after injection of plasma obtained from the subjects of Groups I. and II. (i.e., the controls and young diabetic patients) there was no appreciable alteration in the form of the blood-sugar curve during the period following injection of insulin (Figs. 1 and 2). In the case of the elderly diabetic subjects of Group III., however, it would appear that a preliminary injection of the plasma into the animals resulted in an early arrest of the fall in blood-sugar after insulin; associated with this premature arrest there was a very definite tendency for the blood-sugar to be higher than the control values during the remainder of the experiment (Fig. 3). This effect of a diminished fall and a more rapid restoration of the blood-sugar after injection of the plasma of these patients is particularly evident in Group IV. (Fig. 4), in which the curves of those members of Group III. who seemed to us to give a positive response have been separated from those in whom the response was negative. We wish particularly to call attention to the following points: (1) that during the second 30-minute period following injection of insulin the blood-sugar had already begun to rise; and (2) that after 60 minutes the average blood-sugar exceeds the initial value; in these respects the curves obtained after injection of plasma are in sharp contrast with those of Figs. 1 and 2.

#### DISCUSSION

Our findings suggest that, whereas the plasma of normal and young diabetic subjects produces no alteration in the blood-sugar response of the rabbit to insulin, the plasma of some elderly diabetics, of the type which we have defined, injected under similar conditions profoundly modifies the action of insulin.

During the period of our experiments, and with the dosage of insulin used, the average blood-sugar of untreated rabbits shows a progressive fall, with some slight tendency to rise during the final period. In comparison it will be seen that the alteration in the average blood-sugar curve following injection of a plasma with which a positive result was obtained is confined to the end of the curve (Fig. 4); the curves of the injected animals and controls fall together during the first 15 minutes, and then diverge, the blood-sugar of the injected animals rising rapidly above that of the controls. Because the initial rate of fall of the blood-sugar is the same in both treated and untreated animals, it would seem that there is no question of any directly acting anti-insular substance in the plasma; in other words, there is nothing in the positive plasma capable of affecting the rapidity of the initial response of the animal to insulin.

In the normal animal a compensatory mechanism becomes effective when the blood-sugar falls to a level determined by the amount of insulin injected and the blood-sugar begins to return to its original level. The period of our experiments being relatively short, in our control animals this mechanism has not had time to produce an appreciable rise in blood-

sugar, but the injected animals giving a positive result appear to be sensitised to its action and in consequence their blood-sugar rapidly regains its initial value.

Observations on the action of anterior pituitary extracts on the blood-sugar response of animals to insulin which bear a close resemblance to our findings have already been recorded. Cope and Marks<sup>6</sup> have studied the effect of hypophysectomy on the response of the rabbit to insulin. These workers found that although hypophysectomy did not alter the rate of fall of the blood-sugar after insulin, the recovery phase was practically absent, so that the blood-sugar continued to fall during the late stages of the curve. Rupp<sup>7</sup> and Houssay<sup>8</sup> have shown

genolytic substances in human serum is that of Anselmino and Hoffmann<sup>10</sup> which appeared shortly after we began our experiments. These authors claim to have demonstrated that serum from diabetics, when injected into rats, results in a marked diminution of the liver glycogen which reaches a maximum in 2-3½ hours. They made no determinations of the blood-sugar of their animals but claim to have found a considerable increase in the blood ketone bodies coincident with the fall in liver glycogen. The active substance was found to be present in all diabetics and without relation to the type or severity of the disease. The same substance was absent from normal human serum during fasting but appeared in response to carbohydrate feeding. Anselmino and Hoffmann

EFFECT OF PRELIMINARY INJECTION OF PLASMA ON THE BLOOD-SUGAR RESPONSE TO 0.2 UNIT OF INSULIN INTRAVENOUSLY

FIG. 1.—Group I.; 9 normal controls.

FIG. 4.—Group IV.; 6 members of Group III. giving positive response. Average of 10 curves.

that secretion of adrenaline by the adrenal glands is an important factor in the restoration of the blood-sugar in hypoglycæmia, and Cope and Marks<sup>6</sup> were able to demonstrate that adrenaline appeared in the blood of their hypophysectomised animals although no rise in blood-sugar occurred, and attributed this failure of the normal compensatory action of adrenaline to the absence of an anterior pituitary factor necessary for the discharge of glycogen from the liver by adrenaline. The effect of injection of a crude saline extract of the anterior pituitary on the blood-sugar response of the rabbit to insulin was also investigated by Cope and Marks.<sup>6</sup> After preliminary treatment of the animals with these extracts, insulin produced a greatly curtailed hypoglycæmia associated with a tendency for the blood-sugar to rise to a high level, very much as in our own experiments; with particularly potent extracts these effects were manifested within a few hours of injection. These findings have since been confirmed by Young,<sup>9</sup> whose diagram of the changes in the blood-sugar response of rabbits to insulin during the first hour after injection of Prolactin (an anterior pituitary product) bears an extraordinary resemblance to our own curve in Fig. 4.

The only work with which we are acquainted which bears directly on the question of the glyco-

believe the substance responsible for these effects is the same body as that which they have isolated from the anterior lobe of the pituitary.

While we have carried out a few experiments on the effect of injected diabetic plasma on the liver glycogen and the blood-sugar response to adrenaline in animals we are not, as yet, in a position to express an opinion on this aspect of the subject. Though we selected elderly, obese, hypertensive, glycosuric subjects as constituting a well-known clinical type, the only obese, non-hypertensive patient with glycosuria, whom we have examined, gave a positive response. It would seem, therefore, that hypertension is not an essential part of the syndrome. None of our patients who gave a positive response showed definite symptoms of pituitary dysfunction, with the possible exception of obesity, but in view of the known dissociation of pituitary symptoms we do not regard this as invalidating the hypothesis that their disorder was due to a disturbance of this gland. Though obesity in the Fröhlich syndrome is associated with increased sugar tolerance, a condition resembling that seen in the hypophysectomised animal, obesity in the Cushing syndrome is accompanied by a definite lowering of tolerance to sugar.

It may be pointed out that at the moment the position of the pituitary in the control of

carbohydrate and fat metabolism is obscure: from the literature it would seem that at least three principles are involved: (a) the glycogenolytic principle of Cope and Marks<sup>6</sup>; (b) the gluconeogenic factor of Soskin,<sup>11</sup> which controls the production of sugar from fat; and (c) a ketogenic factor described by Burn and Ling,<sup>12</sup> Anselmino and Hoffmann,<sup>10</sup> and others. The glycogenolytic and gluconeogenic principles are termed diabetogenic substances; there seems to be general agreement that the diabetogenic and ketogenic principles of the anterior pituitary are distinct bodies (see Collip<sup>2</sup> and Anselmino and Hoffmann<sup>10</sup>), a finding which has a possible bearing on the occurrence of glycosuria unassociated with appreciable ketosis in obese persons.

It is remarkable that injections of diabetogenic substances into animals do not immediately result in an elevation of the fasting blood-sugar level, although other signs of their presence are manifested. While Cope and Marks<sup>6</sup> found that an extract of the anterior pituitary in some instances raised the fasting blood-sugar to hyperglycæmic levels, Anselmino and Hoffmann<sup>10</sup> state that their purified extract had no definite effect on the blood-sugar; in Houssay's<sup>4b</sup> experience anterior pituitary preparations raise the blood-sugar only after a considerable latent period. In our animals the fasting blood-sugar was not altered by injection of positive sera.

Our knowledge of the metabolic disturbances in diabetes will undoubtedly be considerably extended as the thesis that the anterior pituitary gland and the pancreas act antagonistically in the control of carbohydrate metabolism is developed. It would appear that any alteration in the balance of these opposed influences must lead to abnormal carbohydrate metabolism. According to Houssay<sup>14</sup> the liver alone is essential for the manifestation of the diabetogenic action of pituitary extracts, and Soskin<sup>15</sup> has suggested a theory of the maintenance of the blood-sugar level based on the view that the pituitary and pancreatic factors act through the medium of the liver.

The significance of the low R.Q. characteristic of the diabetic condition has recently been called into question by Soskin.<sup>3</sup> Contrary to accepted opinion it would seem that the depancreatized dog, and, presumably, the human diabetic, is able to oxidise carbohydrate in a normal manner. The effect of the oxidation of carbohydrate on the R.Q. is, however, considerably masked by the simultaneous conversion of fat to carbohydrate, a process having a low R.Q.

Our finding that in certain cases of diabetes the blood contains a substance with a diabetogenic action is against the view that lack of insulin is always responsible for the disturbances of carbohydrate metabolism of the "diabetic." The close similarity between our results and those obtained by others with extracts of the anterior pituitary suggests that the blood of those of our patients who gave a positive response contained an excess of a factor capable of modifying the hypoglycæmic action of insulin in a manner resembling that of the anterior pituitary principle. Having regard to the relatively small volume (10 c.cm.) of plasma injected into the rabbits, the concentration of active substance in these bloods must have been very considerable.

#### SUMMARY

The blood plasma of some elderly, obese, glycosuric patients, when injected into rabbits, was found to diminish the hypoglycæmic action of insulin in a manner closely resembling that observed by other

workers with extracts of the anterior pituitary gland. The plasma of young diabetic patients and of normal control subjects gave entirely negative results. The possible bearing of this finding on the pathogenesis of human diabetes is discussed.

### A CASE OF ACUTE FEBRILE ANÆMIA DUE TO DENTAL SEPSIS

BY PAUL C. GIBSON, M.D., B.Sc., M.R.C.P. Lond.  
PHYSICIAN TO THE TORBAY HOSPITAL

NEARLY fifty years ago William Hunter remarked on the similarity between what he called *septic anæmia* and *Addison's anæmia*. He was convinced that they were distinct diseases, but he believed that in both, oral sepsis played a part; that in the one case the relationship was a direct one, while in the other it was indirect. During the past fifty years attention has been mainly directed to Addison's anæmia, and controversy has been keenest about its relationship to focal sepsis. The discovery in 1923, by Minot, of the special efficacy of liver, completely reorientated our ideas about this and other allied anæmias, emphasising the prime importance of a deficiency factor in this particular group. To-day the scene has shifted; for the moment the theory of Addison's anæmia has been satisfactorily shelved, and the centre of dispute is another group of anæmias, which, although called by another name, resemble in many ways the *septic anæmia* of Hunter. Whether or not focal sepsis plays a part in their causation is still a moot point, but the story of these anæmias is not yet finished, and, in the light of more perfect knowledge, it may be found that Hunter was right after all.

In the course of a discussion at the Royal Society of Medicine in 1933, Tidy<sup>1</sup> referred to cases of *acute febrile anæmia*, recalling the kind of nickname given them by Parkes Weber, "acute breakdown of the blood," a term that was not intended as a distinctive label, but which has nevertheless a useful implication suggesting a severe, passing anæmia of sudden onset. Among this group of febrile anæmias is the *acute hæmolytic anæmia*, to which Lederer<sup>2,3</sup> drew attention in 1925. The outstanding features of his cases were the acuteness of the development of the symptoms; evidence of very rapid erythrocyte destruction;

extreme regenerative activity of the bone-marrow; rapid recovery after therapy; and absence of sequelæ. In the succeeding years a considerable number of similar cases have been reported. Lederer himself remarked that the disease was not an infrequent one. A review by O'Donoghue and Witts<sup>4</sup> in 1932, of 36 cases, and a report by Joules and Masterman<sup>5</sup> in 1935, of 4 cases, makes it probable that the condition is more common than is generally supposed.

O'Donoghue and Witts are inclined to believe that the disease is a distinct clinical entity, but in regard to its pathology they say "the morbid anatomy of the disease is as suggestive of an infection as the clinical picture, but there is no convincing evidence that streptococci or other familiar micro-organisms are the cause." A constant feature of these cases is the absence of demonstrable micro-organisms from the blood. If we assume that streptococci or other familiar micro-organisms are the cause, it follows that the materies morbi must be a soluble toxin. If this is so, it is not surprising that the source of the toxin is often hard to find. Cryptic infections are the bane of medical practice, and they are likely to continue to be so until a satisfactory test is found (perhaps on the lines of the pathogen selective culture test) which will supply convincing evidence of infection by a particular organism, isolated from a suspected focus.

If the toxæmic state resulting from focal infection is indeed the primary factor in the causation of *acute febrile anæmia*, we must look for other factors to account for the differences that distinguish a particular group, such as the Lederer group, from other anæmias of septic origin. From the almost specific effect of blood transfusion in most of the reported cases it may be supposed that anoxæmia is such a factor. It seems as though, in the course of a toxæmic process which is affecting the blood and producing anæmia, when the available hæmoglobin falls below a certain critical level, a breakdown of the hæmopoietic system follows—such a state being often associated with a febrile reaction. It is believed that the actual stimulus to hæmopoiesis in anæmic states is diminished oxygen tension. Presumably if oxygen tension falls below a certain level the stimulant effect is succeeded by depression. If, as a further result of the toxæmia, the source of hæmopoietic factor is poisoned, the scene is set for the production of an anæmia of Addisonian type. To restore the balance of health, one or more of three methods of treatment might be expected to be effective: (1) reinforcement of the hæmoglobin supplies; (2) reinforcement of the natural supply of hæmopoietic factor; (3) elimination of the infection. Of all these methods, the swiftest and surest, in the average case, would be an adequate blood transfusion. It is to be expected that an adequate supply of liver or stomach extract would be equally efficacious in some cases. But, assuming that focal infection is at the root of the trouble, these can only be regarded as palliative remedies; the tracking down and suppression of the source of infection must be of primary importance.

It is interesting to recall the case of Exner and Ive,<sup>6</sup> reported in 1925, and another case reported by Venables<sup>7</sup> in 1926. In both of these, acute hæmolytic anæmia was associated with dental sepsis. In the case of Exner and Ive, after two blood transfusions had been ineffective, a third one, given after the mouth had been cleared of infected teeth, was dramatically successful. In Venables's case, blood transfusion was ineffective, dental extraction was considered inadvisable on account of the patient's

condition, and a desperate situation seemed to be saved by the use of an autogenous vaccine prepared from a dental swab. In one of Lederer's six cases three transfusions of 500 c.cm. each were without beneficial effect; in fact the patient was worse after the third one, but she eventually recovered without any further treatment.

### Case Record

The case that is the subject of this communication has much in common with those reported by Exner and Ive and by Venables.

### HISTORY

Female, aged 23, domestic servant. Diphtheria at 4 years old. Jaundice at 14 and at about the same time she had two teeth extracted which was followed by a septic mouth and a septic toe. She was otherwise well until about two years before admission. She then began to get tired easily and found her work more and more of an effort. In March, 1934, she began to have pain in her left hip. After a week in bed the pain improved. She went home for six weeks, remaining more or less free from pain. Three days after starting work the pain returned and she was sent to St. Mary's Hospital, Paddington, for investigation. She went there on May 11th and attended as a surgical out-patient. She complained of pain in the left thigh, radiating to the heel, also of breathlessness on exertion and palpitation. It was considered that she was suffering from sciatica and she was transferred to the medical department. Radiograms of both hip-joints showed nothing abnormal, a group of calcium shadows appeared in the right pelvis which were thought to be calcified glands. Clinical examination showed that she was thin and pale and had very evident dental sepsis; temperature 98° F., pulse-rate 120. Nothing else was found wrong. She was sent to have dental treatment and told to report again afterwards.

In June she had four teeth extracted, after which her condition remained much the same. At the end of July she came to Torquay to recuperate. Shortly afterwards the pain became worse and the left shoulder became affected. She went to consult a doctor, walking some little way to his house. He noted that she was very pale and so sent her to the hospital for a blood count, telling her to come and see him again in a couple of days so that he might advise her in the light of the report. She did not come and when he called at her house he found her in bed very ill. He immediately sent her into the Torbay Hospital. She was admitted on August 17th, 1934.

By reference to the temperature chart the last illness can be divided into three phases: (1) A febrile phase, lasting for twelve weeks and two days. (2) An afebrile phase, lasting nine weeks and five days. (3) A final phase, also febrile, lasting five weeks and three days, which ended with her death, six months after admission. The accompanying Tables summarise the main features of blood counts and other special investigations and of the treatment adopted.

### THE FIRST PHASE

At the time of admission she was thin and very pale. There was no suggestion of jaundice then, or at any time during the illness. The pulse-rate was 120, the temperature swinging from 97° to 103°. Nothing notable in the lungs. First heart sound blurred. Blood pressure 120/80. Spleen easily felt two fingers-breadth below the costal margin. There was pain in the left hip and shoulder-joints. The gluteal muscles on the left side were wasted. The urine contained neither albumin nor sugar. The blood showed a megaloblastic anæmia. Bacteriological and serological tests gave no evidence of a blood infection. It was thought that she had a primary anæmia and liver injections were started on Sept. 2nd.

On Sept. 15th her condition was steadily deteriorating and she was given a transfusion of 200 c.cm. of her father's blood. We could not be sure that he was of the same group, his cells were unaffected by her serum but her own

cells auto-agglutinated. There was a slight improvement after this and so, on Sept. 20th, she was given another transfusion of 250 c.cm. from the same donor. On the following day the red cell count had fallen still lower and no reticulocytes were seen. On Sept. 27th we detected what we took to be a presystolic thrill and murmur. She seemed to be dying and her parents were summoned to await the end.

Six days previously Ventriculin had been started. This was repellent to her and it was only by constant persuasion that she could be induced to take it. On Oct. 10th, encouraged by a rise in the reticulocytes, we increased the dose of ventriculin. It was found that 20 g. could be given in four large cachets. From this time onwards her condition progressively improved. The rapid improvement in her colour was very striking. Within four weeks the red cell count had reached 3 millions; at this point the fever abruptly ended and the first phase came to an end.

The salient features of this stage were the alternations in the clinical picture. At first she seemed to have a primary anæmia, and then the appearance of what we took to be a presystolic murmur, at the time when hæmatinic treatment had apparently failed, was very suggestive of infective endocarditis, while, later, the sudden improvement soon after ventriculin was added to the daily ration of liver seemed to point conclusively to Addison's anæmia.

Pil. ferri redact.	grs. 10 t.d.s.	Dec. 23rd	Death.

On Nov. 3rd it was recorded that the spleen was not felt and the first sound at the mitral area was clear. It was evident that we had been deceived by a doubled first sound. A reference from a paper by Poynton, Thursfield, and Paterson<sup>8</sup> on acute anæmia in children so exactly describes what occurred in this case that I feel justified in quoting it. They say:—

“As the anæmia progresses the first sound at the impulse becomes short and abrupt, and if in addition it is slightly reduplicated, the simulation of mitral stenosis is very close. We have not detected, in such cases, a definite thrill, but there is invariably a soft systolic murmur after the abrupt first sound. When the degree of anæmia is very profound, a diastolic murmur may become also evident at the base, with its maximum usually, just to the left of the sternum in the second intercostal space. When, in addition, there are fever, purpura and enlargement of the spleen, the resemblance to a progressive endocarditis is so close as to give rise to the greatest difficulty

in diagnosis. It is equally remarkable, when there is improvement in the anæmia, how completely these cardiac signs alter and return to normal."

THE SECOND PHASE

During the nine weeks that followed the abrupt cessation of the swinging temperature, she remained afebrile with the exception of four isolated rises, none of which lasted more than 48 hours. It was a period of steadily improving health. The blood count rose progressively and her weight increased from 7 st. 3 lb. on Nov. 20th to 8 st. 5 lb. on Dec. 29th. The results of a fractional test-meal and a van den Bergh test showed that she had a normal gastric acidity, and that there was no evidence of hæmolytic at the time of the test. And so the idea of Addison's anæmia had to be abandoned and the teeth again became suspect.

It was decided to wait, before having these dealt with, in order to get her as physically fit as possible. She was given massage, and, later, a course of ultra-violet light baths and she gradually resumed a normal life. About Christmas time arrangements were made for her to stay with friends to complete her convalescence. On Dec. 16th she began to complain again of pain in her shoulder and hip. On Dec. 23rd this was so severe that an injection of omnopon was needed to relieve it. Her general condition remained good. On Jan. 4th her teeth were radiographed. It was found that she had an apical abscess in one of her premolars and five other teeth appeared to be unhealthy. There was a brisk rise of temperature on the day following the X ray examination, which subsided after 48 hours. The pain continued and her weight began to fall and so it was decided that the infected tooth should be extracted. This was done under gas on Jan. 12th.

From the apex of the tooth a growth of *Streptococcus viridans* was obtained, both from a direct culture and from implantation into her own blood. A vaccine was prepared with which it was hoped to immunise her before proceeding to further extractions. One week after the extraction the swinging temperature returned and she entered on the final phase of her illness.

THE THIRD PHASE

The beginning of the final phase, which started on Jan. 18th, coincided with the onset of the first menstrual period that she had had since her admission. During the succeeding week the temperature was not alarming and it was thought that it might be associated with menstruation. But her general condition deteriorated rapidly, the pain in her hip and shoulder was continuous and at times agonising.

On Jan. 26th, the vaccine being ready, she was given a subcutaneous injection of 50,000 organisms. During

the succeeding 24 hours the temperature was subnormal. The same dose was repeated on Jan. 30th and on Feb. 1st without result. On Feb. 4th she was given 75,000, still without effect. The temperature was now swinging from 97° to 103°. We felt that there was no time to lose and decided to give her full doses of antistreptococcal serum and then to extract the suspected teeth. From Feb. 8th to 14th inclusive she was given, intramuscularly, 10 c.cm. of concentrated polyvalent antistreptococcal serum twice daily. On Feb. 9th the five suspected teeth were extracted. After this the temperature began to abate and we hoped that she was going to improve. On Feb. 10th she began to get serum reactions; she vomited frequently and a giant urticaria developed all over her body. These troubles added to the pain were becoming intolerable and so, on Feb. 15th, we stopped the serum. But it was soon evident that she was failing, the pulse-rate rose steadily, the liver became hard and enlarged (being palpable five fingers-breadth below the costal margin), there were crepitations at the bases of both lungs, and purpuric spots appeared on the abdomen.

On Feb. 24th she died, five days after the completion of her sixth month in hospital.

Conclusion

A peculiarly interesting feature of this case is the contrast presented by its initial and final phases. During the first phase the only symptom was extreme prostration, the pain was forgotten soon after admission. The dominating feature apart from pyrexia, which was common to both phases, was a grave anæmia. Although the heart sounds were altered there was no evidence of circulatory failure. During the final phase pain was the dominating

Showing temperatures, reticulocyte counts, and red cell counts accurately superposed. The maximum temperature range for each day is given, taken from four-hourly charts, except from Nov. 20th, 1934, to Jan. 27th, 1935, during which period morning and evening charts only were used. The dosage of the preparations referred will be found in Table III. Camp.=Campolon. A=Blood transfusion (200 c.cm.). B=Blood transfusion (250 c.cm.). 1=Radiogram taken. 2=One tooth extracted. 3=Five teeth extracted.

feature. The blood picture was normal and no alteration in the heart sounds was noted, but as the fever progressed her tissues were rapidly swamped by acute congestive failure.

The evidence that incriminates the *Streptococcus viridans* as the cause of death provides reasonable proof of the cause of the anæmia. It is extremely unlikely that the two febrile phases were related to essentially different causes. The presumption is that the first phase was one of the manifold effects attributable to streptococcal toxin, whereas the final phase was due to invasion of the blood and tissues by the organism itself. The acute onset, the rapid development of anæmia and its equally rapid subsidence, the megaloblastic reaction, and the extreme pyrexia remind one of the cases described by Lederer; but the absence of any evidence of hæmolysis excludes the use of the term acute hæmolytic anæmia. In the present state of our knowledge, admittedly very imperfect, it seems advisable when referring to this type of anæmia to avoid too precise a nomenclature. In attempting to define a new type it is desirable to explore the common ground thoroughly before emphasising points of difference.

There are two features of this case that are of special interest: that it was a true an hæmopoietic anæmia, and that it was caused by dental sepsis. To justify the first contention it will be necessary to show that the response to specific substance was of the same order as occurs in Addisonian anæmia. Minot and Castle<sup>9</sup> have recently summarised the essential features of the reticulocyte response to specific substance in pernicious anæmia. The points of interest to us are as follows:—

1. The reticulocyte response that follows the giving of active substance to cases of pernicious anæmia almost always begins within two to ten days.

2. If, following the administration of a substance during a first period, there is, during a second period, an orderly response of reticulocytes, no matter of what degree, to a second substance, this substance is known to be more potent than the first.

3. There is a direct relationship between the amount of specific substance given and the peak of the reticulocyte value.

4. The daily dose of liver or desiccated hog stomach that is needed to produce a maximal response is 500 and 30 g. respectively.

Daily intramuscular injections of 2 c.cm. of Campon—that is, the equivalent of 500 g. of liver—were started on Sept. 2nd. Except for a low peak reaching a value of 1.6 per cent. on Sept. 5th the reticulocytes diminished steadily, and on Sept. 21st they were reported as “absent.” Ventriculin was started on Sept. 22nd, the initial dose, 10 g., being only one-third of that considered necessary to produce a maximal response. Three days later the reticulocytes had risen to 1.2 per cent. On Oct. 11th normoblasts reappeared in the blood and the reticulocytes had risen to 5 per cent., the first peak in the curve. On Oct. 10th the dose of ventriculin was doubled; eight days later the reticulocytes had increased to 6 per cent., the second peak on the curve. Applying the principles of Minot and Castle it would seem that ventriculin was more potent than liver. While it is likely that the extent of the reticulocyte response was affected by the fever, it cannot be maintained that the eruption of normoblasts and the improvement in the red cells were attributable to this cause. The red cell count began to improve on Oct. 6th, when the fever had abated, but the progressive improvement in the blood was entirely

unaffected by the six weeks of fever that followed this temporary remission. It seems, therefore, that, in this case of febrile anæmia, ventriculin exerted its specific effect, and that this effect was of the same order as would be expected in a case of pernicious anæmia.

We have now to consider the second contention, that the illness was due to dental sepsis. It is unfortunate that a blood culture was not taken during the final phase and that a post-mortem examination was not done, but the clinical evidence alone is sufficiently convincing. Dental sepsis had marred her life from the age of 14, when she developed a septic mouth and septic toe after the extraction of two teeth. In May, 1934, when she was investigated at St. Mary's Hospital, it was thought that her pain was accounted for by sciatica, due to very obvious dental sepsis. During her last illness, immediately after her teeth were radiographed, there was a brisk febrile reaction, suggesting that the local tissues were damaged by the X rays, so facilitating the escape of organisms or their toxins into the blood. The X rays revealed an apical abscess in a premolar, which was extracted. Following this, after a latent period of seven days, there developed, with sudden onset, a condition that was indistinguishable from septicæmia. The accumulated value of this evidence should be as convincing as would have been the demonstration of a streptococcus in the blood.

By way of a corollary it seems appropriate to emphasise the risk attending the extraction of septic teeth. The fact that a scraping from the apex of an infected tooth, implanted into her own blood, yielded a growth of *Streptococcus viridans* is of some significance. It was an application of the pathogen selective culture test. E. C. Lowe,<sup>10</sup> applying this test to specimens from infected teeth, found in 57 per cent. of his cases, while the direct cultures yielded multiple types of growth, a pure growth of streptococci was obtained from the auto-blood cultures. The significance of the test is that it implies the ability of a particular organism to grow in the patient's blood, whereas other organisms not pathogenic to the patient are unable to do so. Supplementing this observation are the findings of C. C. Okell and S. D. Elliott.<sup>11</sup> These authors found that within a few minutes after the extraction of teeth from obviously septic mouths a transient streptococcal bacteriæmia, lasting a few minutes, was observed in 75 per cent. of their cases. These two observations taken together afford an explanation of the many fatalities, recorded and unrecorded, that have followed the extraction of septic teeth. If these findings are generally applicable they should serve as a serious warning, indicating that, in patients whose resistance has been lowered by prolonged illness, the extraction of infected teeth, without previous preparation of the patient, is an operation fraught with grave risk. What this preparation should be is suggested by the case of Venables,<sup>7</sup> in which a vaccine prepared from a dental swab seemed successful in suppressing the infection. In our case, action was forced by circumstances, the pain was incessant, and it seemed imperative to remove the suspected teeth in order to relieve it. With the greater courage of conviction we might have persisted with vaccine treatment with better effect. But conviction can only come of knowledge and, in dealing with focal infections, without means at our disposal for identifying the offending organism with any degree of certainty, we are still left to grope in the dark.

I wish to express my thanks to Dr. W. D. Brooks, medical registrar to St. Mary's Hospital, for a most helpful report, and to Dr. T. C. Hunt and Mr. C. W. G. Bryan, physician and surgeon respectively to the out-patient department at St. Mary's, for their kind permission to make use of this report. I would also acknowledge the valuable help received from Dr. H. A. Fielden and Dr. Basil Halliwell, pathologist and radiologist respectively to the Torbay Hospital, for various investigations.

I particularly desire to record my gratitude and indebtedness to Sister Tozer of the Torbay Hospital for her invaluable help in ensuring the accuracy of the temperature charts and of the details of treatment, and to Mr. Horace Mountford, Dr. Fielden's assistant, who was responsible for all of the blood counts. Without their help it would have been impossible to have collected reliable data for this publication.

## DECLINE AND FALL OF THE UNDESCENDED TESTIS

BY EDWARD MCLELLAN, M.B. Lond., F.R.C.S. Eng.

SURGICAL REGISTRAR, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON

NOTHING could encourage the enthusiastic investigator in the happy exercise of self-deception more than an inquiry into this subject, which has exercised the imagination and ingenuity of embryologists, biologists, anatomists, and surgeons for generations.

Theories abound on the cause and course of the descent of the testis, and few of them are supported by anything which resembles scientific proof. This is not surprising inasmuch as theory has been based upon embryological evidence, and this, in the human at any rate, is inevitably incomplete.

Recently a certain amount of valuable investigation has been carried out from the clinical standpoint by Spence and Scowen,<sup>1</sup> who have been able to effect the descent of the testis by the use of gonadotropic hormones, but no explanation of their results has been forthcoming, nor has it been possible to state which cases are suitable for this form of treatment and which are not.

At the Hospital for Sick Children, Great Ormond-street, I have had the opportunity of investigating 25 cases of undescended testis over a period of eighteen months, and in this paper I propose to make observations upon the following matters: (1) the normal descent of the testis and the processus vaginalis, and their relation to one another; (2) the types of undescended testis from the clinical standpoint; (3) an explanation of the satisfactory effect of Pregnyl in certain cases and not in others; and (4) the unsatisfactory late results of operative treatment and a suggested remedy.

### NORMAL DEVELOPMENT

Many factors have been described as contributing to the descent of the testis: the disappearance of

the cephalic end of the mesonephros causing a relative caudal descent; the return of the gut from the cord to the abdomen thus separating further the anterior from the posterior wall; the contraction or atrophy of the gubernaculum. All these play their part, but to them must be added two other factors which I believe to be of paramount importance: the testis must be of normal size, weight, and development, and its descent must be preceded by a normal descent into the scrotum of the processus vaginalis.

It is now known that the testis descends along the course laid down for it by the processus vaginalis, and in my opinion failure to descend may be due to:

- (a) A small, undersized, underactive testis.
- (b) An abnormal processus vaginalis.
- (c) The development of adhesions between testis and adjacent structures during its descent.

The gubernaculum acts as a guide in the descent, but I cannot believe that it plays an active part in drawing the testis down. It is possible in any male infant to displace the testis from the bottom of the scrotum to the external abdominal ring, and frequently into the inguinal canal, with the greatest of ease; and this would not be possible if the testis were in any way anchored to the bottom of the scrotum by a contracted or atrophied gubernaculum.

Keith's original description of the testis descending with the processus vaginalis "like a log on a sledge" has been accepted without question, but there is evidence, both embryological and clinical, that the descent of the processus vaginalis precedes in time as well as situation that of the testis.<sup>2</sup> From an examination of embryological sections, for which I am very greatly indebted to Dr. R. J. Gladstone of King's College, it is clear that the path which the processus vaginalis is to take is made plain by a dissolution of the cells, a cleavage of the tissues leaving a space which the processus then occupies. Kirk<sup>3</sup> has shown clearly, by a very full and painstaking research, that the same is true in rabbits and marsupials, and that the processus vaginalis is completely formed and is in the scrotum long before the testis has descended.

What causes the cleavage of the cells and the descent of the processus vaginalis? It is not unreasonable to suppose that the stimulus is hormonal and of an oestrogenic nature. Harold Burrows<sup>4</sup> in a most excellent investigation has proved that in mice it is possible to produce inguinal herniæ at will by the administration of oestrin, provided the testes were almost or quite mature. He has also shown that oestrin tends to inhibit the descent of the testes and prevent their maturation.

Now it is clear from the work of Zondek<sup>5</sup> that during the early months of pregnancy the oestrin content of the maternal blood is very low, and that towards the end of pregnancy it rises rapidly, while the anterior pituitary secretion remains at a relatively high level throughout and falls slightly towards the end. Suppose that this state of affairs is disturbed and there is an excess of oestrin or a relative lack of anterior pituitary substance during pregnancy. The result may easily be the development in the male fetus of a normal or greater than normal processus vaginalis, together with small and underdeveloped testes. The combination of these circumstances may be responsible for the imperfect descent of the testes.

If these views are correct it follows that there is a stage in the development of every male child when the processus vaginalis reaches the bottom of the

scrotum and the testis is still in the pelvis or in the inguinal canal, and a potential hernial sac is present. What then causes the closure of this sac? It is common ground that the processus first closes at the internal abdominal ring and later at the external abdominal ring. It is also agreed that the testis pauses in its descent at the internal abdominal ring for about three months (4th to 7th) and at the external ring for one month (8th). If we bear in mind that the fœtus is in an attitude of flexion with the thigh in contact with the abdominal wall it follows that considerable pressure must be made on the testis as it lies at these points of pause. The result may well be that which we hope to obtain clinically by applying a wool truss to a similar point after the birth of the infant in an attempt to cure an inguinal hernia. The pressure in the antenatal state is, however, applied more accurately and more consistently, and the result is equally more effective.

There may be a hormonal factor in addition to the purely mechanical one. If œstrogenic hormones have the effect of increasing the processus vaginalis it is possible that antagonistic hormones of the anterior pituitary group have an obliterative effect, and mention will be made of this in the clinical study later.

DEFINITION AND CLINICAL CLASSIFICATION

A testis may be said to be undescended if, after painstaking and persistent attempts have been made to push or pull it down into the scrotum, it remains at a higher level at some point on its normal course of descent.

For examination I place the child lying on a couch, with the legs slightly apart and slightly flexed, and with the abdominal muscles relaxed. I then attempt to press the testis downwards along its course by slow and firm and steady pressure, commencing this movement as high as the iliac fossa. If after repeated attempts the testis fails to enter the scrotum it is considered to be undescended. The importance of this examination will be apparent when I say that no less than 12 patients with "undescended testis" were sent to me for treatment by practitioners who all had special experience in the examination of children, and in all I was able to get the testes satisfactorily into the scrotum. These call for no treatment and will with certainty descend in the course of time. With a less energetic examination technique they would certainly have found their way into the "cures" column of the pregnyl treatment table.

Clinically my cases can be classified as follows:—

Group.	General physical development.	Development of testis.
I	Normal.	Normal.
II	Subnormal.	Subnormal.
III	Normal.	"

The results of pregnyl treatment in these cases according to the various groups are shown in the Tables.

In addition to these groups there were three patients in whom an operation had been performed in the inguinal region, and all three failed (Table II.).

The injections were given once a week and the dose was 500 rat units, given intramuscularly into the buttock. There was an interval of 2 to 3 months after each course of six injections. My idea was to make the testis descend as slowly as possible in the hope of causing an obliteration of the processus vaginalis, in the manner similar to that which I

believe to occur normally during the later months of intra-uterine life. In only one of the 25 boys that have been so treated is there any hernia that can be recognised clinically although there is a history of hernia in 4. This is a matter which calls for further investigation and which I am undertaking.

TABLE I.—Summary of Results

Observations.—Cases 12 and 13: hypospadias; Cases 23 and 25: orchidopexy; Case 24: double herniotomy. Imp.= improved.

It appears from my series that cases in Group I are entirely unsuitable for treatment by pregnyl, those in Group II are eminently suitable, and those that come into Group III may or may not respond favourably.

It is, naturally, very difficult sometimes to say whether the testes are small and undeveloped for the size of the boy but in my opinion these doubtful cases are worthy of a trial. No harm, at any rate, will be done and an operation may be saved. I have experienced no alarming reactions from these injections and there are no contra-indications (other than that of expense) in healthy children. There is occasionally slight stiffness of the buttock for a day or two, and two children developed a rash after each course of injections; it only lasted a few days. Parents often volunteer the information that the boys improve in health and general development during their treatment.

EXPLANATION OF RESULTS

It is obvious that the type of case which responds to pregnyl (Groups II and III) is that which also

comes under the heading (a) and (b) in the classification given earlier in this article; during intra-uterine life he may have been subjected to an excessive amount of oestrin or a deficient amount of anterior pituitary substance. By administering pregnyl we simply remedy, at a late stage, this state of hormonal imbalance, with the result that the testis develops, becomes larger, heavier, more mobile, and more readily follows the course which has been prepared for it by the processus vaginalis. This change in the physical condition of the testis is a most noticeable and constant feature.

The failures (Group I) are the cases which occur under the heading (c)—namely, normal testes in normal children, which have been arrested in their descent by adhesions to other structures in the abdomen or inguinal canal. It is the rule to find, when operating on these children, that great difficulty is experienced in dissecting the testis free from the structures in its vicinity.

#### LATE RESULTS OF ORCHIDOPEXY

I have recently carried out an investigation of 15 cases of undescended testis which were operated upon by the late Mr. H. Tyrrell-Gray at the Hospital for Sick Children, Great Ormond-street, between five and ten years ago. In every case the testis was still in the scrotum, a testimony to the perfect technique of a brilliant operator, but in every case the testis was considerably smaller than its normal neighbour. The same condition has been noted by Burdick and Coley<sup>6</sup> in a very much larger series.

I would therefore suggest that in those patients with undescended testis that belong to Group I, and who undoubtedly call for operative treatment, a pre-operative and a post-operative course of pregnyl should be given. The pre-operative course of, say, six injections will bring about some increase in the size of the testis, and this will facilitate the operation, while the post-operative course of, say, twelve injections will do something to prevent the atrophy of the testis which is such a constant feature.

I am greatly indebted to Mr. Eric Lloyd and Mr. Simpson Smith who have referred all these children to me and have thereby made this investigation possible. I am also grateful to the Organon Laboratories for supplying the hospital with pregnyl.

**MORE HOSPITALS FOR ESSEX.**—Schemes for the erection of new hospitals by the Essex county council at Chelmsford, Saffron Walden, Colchester, and in the Thames-side district were outlined at a meeting of the county council at Chelmsford on April 8th. The Hospitals' Survey Committee are in consultation with Chelmsford Voluntary Hospital and it is hoped to raise the accommodation of the hospital to a maximum of 200 beds. There is a waiting-list here of 239 patients apart from adenoid and tonsil cases. At Saffron Walden it is suggested that the acutely sick should be dealt with by arrangement with the voluntary hospital. Sixty beds are needed for chronic cases and a site for such a hospital will have to be found. At Colchester the Pope's Lane Infirmary and the Stanway Infirmary will be united and will be in no way a rival to the Essex County Hospital.

## ON THE TREATMENT OF UNDULANT FEVER WITH FOUADIN

BY CHARLES ZAHRA NEUMANN, B.Sc., M.D. Malta

THE intensity and duration of undulant fever vary so much that it is hard to assess the curative value of drugs used in its treatment. Sometimes the illness lasts only ten or fifteen days and causes but little inconvenience; but on the other hand it is common to see patients ill for eight or ten months or even longer, reduced to living skeletons and suffering from the after-effects for perhaps another six months. The temperature, too, may never rise above 100° F. in some cases, whereas in others the hyperpyrexia and delirium give a clinical picture very similar to that of severe typhoid fever.

Several classifications for the different clinical manifestations of undulant fever have been proposed, such as the distinction between an acute type and a chronic. It is not unusual, however, for the acute illnesses to become chronic or for the latter to suddenly flare up into acute. Alternatively the fever may, for no apparent reason, disappear, and rapid recovery may set in; and if a drug has been administered at this period it may easily be given credit which it does not deserve. This illustrates the difficulties inherent in any inquiry into the effect of therapeutic agents used in this disease.

Through the courtesy of the I.G. Farbenindustrie I have been able to treat eight cases of undulant fever with Fouadin, and the results are described below.

Fouadin is a complex compound of antimony and pyrocatechin-disulphonic acid. Pyrocatechin (which is related to adrenaline) is easily oxidised and therefore many of its compounds are unstable. The acid derivatives of pyrocatechin are much more stable, and several metallic complexes have been synthesised by Prof. Hans Schmidt since 1922. Fouadin is antimony bis-pyrocatechin di-sodium sulphonate, and the metal is trivalent. Being non-irritant, it can be injected intramuscularly, and has been widely used in Egypt and in other countries against bilharzia infestations. It is usually injected into the gluteal region, and to adults 1.5 c.cm. has been given on the first day, with 3.5 c.cm. on the second day, followed by 5 c.cm. on alternate days. There is no pain at the site of injection and the drug is well tolerated, no secondary effects having been observed. The above doses are suitable for an average adult male, but the maximum dose in the female patients has been 4.5 c.cm.

**CASE 1.**—A woman aged 23. She was treated at first with anti-melitensis vaccine, both intramuscularly and intravenously. The shock accompanying the intravenous injection was so intense that it was thought advisable not to persist. A fortnight after the onset the temperature was oscillating between 102° and 103° F. and fouadin was injected according to the scheme described above. On the seventh day, after the fourth injection, the temperature ranged between 99° and 100° F. At the eighth injection the patient was afebrile and no further waves of fever were afterwards experienced. During convalescence rheumatic pains made their appearance but were moderate in severity and not unduly troublesome.

**CASE 2.**—The patient, aged 18, had been suffering from fever reaching 105° F. for about eight days when the practitioner was called in. His spleen was found to be enlarged and the Widal reaction was positive to *Micrococcus melitensis*. Fouadin was injected in the usual

manner and at the fifth injection the temperature returned to normal, while the general condition improved so quickly that the patient returned to his work about three weeks after treatment was begun.

CASES 3 and 4.—Two brothers, aged 9 and 11, had been suffering from undulant fever for about a week before treatment was begun. The adult dose was divided between them. The evening temperature was 104° F. in both cases when the injections were started, but at the end of ten days both children were apyretic, each having received a total of five injections. During convalescence, which was otherwise uneventful, rheumatic pains made their appearance; but these were slight and lasted only a week.

CASE 5.—A man of 21 developed a severe toxic form of undulant fever and at the end of the first week his temperature rose to 105° F. He was delirious and the urine contained a small quantity of albumin but no casts. Bronchial catarrh caused a distressing cough with viscid whitish expectoration. It was thought advisable not to exceed 4 c.cm. foudadin per single dose owing to the possibility of causing renal irritation, and treatment was begun as soon as the diagnosis was confirmed by agglutination tests. After three injections the temperature was 103° F. in the evening, and on the twelfth day it had dropped to 101° F., while the general condition had improved considerably. The delirium had disappeared and the appetite was returning. On the seventeenth day the evening temperature was 99° F. and the injections were discontinued, the patient having had a total of nine injections. After three weeks he was completely apyretic and he remained so even on the supervention of slight rheumatic pains about the ankles and the knees. No secondary waves of fever were afterwards registered and the patient returned to work seven weeks after the onset of the disease.

CASE 6.—A boy aged 7. This was a slight case, for the temperature was never above 101° F. and the general condition was fairly good. Only three injections of foudadin were given (1.5, 2.5, and 4 c.cm.). At the end of a week the temperature had dropped to normal, although the patient developed arthritis of the hip-joint. This complication, although not accompanied by fever, lasted for almost a month.

CASE 7.—A girl aged 13. The onset of the disease was very insidious and suggestive of tuberculosis. The child coughed slightly, expectorated a little, and lost weight as well as appetite. An evening temperature of 100°–101° F. made the diagnosis of tuberculosis plausible, but radiographic examinations were negative and no tubercle bacilli were found in the sputum. The fever abated for about a week but then again rose to 102° F., and when it was found that the serum reacted strongly to *Micrococcus meliitensis* in high titres the case was recognised as one of undulant fever. Foudadin was given as in the previous case and after five injections on alternate days the evening temperature dropped to 99° F. On the twelfth day the patient was afebrile. The appetite improved, the evening sweats ceased, and she gradually regained weight.

CASE 8.—A married woman of 32 contracted undulant fever at the eighth month of gestation and was delivered of a normal baby 15 days before the appointed time. On the day of the delivery the temperature rose to 104° F. and three days later it was still 103° F. At this stage foudadin was injected. At the fourth injection the patient's temperature was normal and she recovered completely within two weeks. Incidentally the baby's serum was tested and found not to agglutinate the micrococcus, although the mother's serum reacted in high dilutions.

The number of cases here recorded is too small for any definite conclusion, but further investigation into the action of antimony compounds on the disease seems desirable. In the treated cases there were no waves of fever after the first, although such waves are one of the characteristics of the disease. Foudadin does not appear to influence the onset of certain complications or sequelæ, such as arthritis.

Malta.

## STAPHYLOCOCCAL LEUCOCIDIN

(NEISSER-WECHSBERG TYPE) AND

## ANTILEUCOCIDIN

BY JOYCE WRIGHT, B.M. Oxon.

(From the Wellcome Research Laboratories, Beckenham, Kent)

DURING recent years there has been renewed interest in the properties of staphylococcal toxin and antitoxin; but, presumably owing to the practical difficulties of working with leucocytes, little experimental investigation has been undertaken on their leucocidal and antileucocidal properties.

The action of staphylococcal toxins on leucocytes may be demonstrated by—

(a) The "bioscopic" method of Neisser and Wechsberg (1901), which depends on the observation that, whereas freshly obtained leucocytes reduce methylene-blue to its colourless form under partially anaerobic conditions, similar leucocytes previously treated with toxic filtrates of staphylococci fail to do so.

(b) The microscopic method of van der Velde (1894), who found that, both in vivo and in vitro, staphylococcal toxins cause degeneration of the leucocytes of the rabbit.

(c) The microscopic method of Panton and Valentine (1932), who observed similar destructive action on human leucocytes.

The "Panton-Valentine leucocidin" is different from the  $\alpha$ -hæmolysin (Valentine, 1936) and would thus appear to be different from the toxin which, as here described, destroys the power of the rabbit leucocytes to reduce methylene-blue ("Neisser-Wechsberg leucocidin"). The latter is referred to for convenience as N.W.L. N.W.L. and anti-N.W.L. are the subject of this investigation, with special reference to their relationship to hæmolysin and antihæmolysin.

### TECHNIQUE

The method is a modification of the Neisser-Wechsberg technique, and is carried out with ordinary sterile precautions.

*Reagents.*—The following reagents are required:—

*Aleuronate* (5 per cent.) + *potato starch* (3 per cent.) in disodium phosphate (0.2 per cent.), steamed half an hour, after which the pH should be 7 to 8. (Aleuronate obtained from R. Hundhausen, Stärkefabrik, Hamm-in-Westfalia, Germany.)

*Sodium citrate* (1 per cent.) in saline (0.85 per cent.), steamed half an hour.

*Locke-Lewis fluid* (NaCl 0.90 per cent., glucose 0.10 per cent., KCl 0.042 per cent., CaCl<sub>2</sub> 0.024 per cent., NaHCO<sub>3</sub> 0.05 per cent.), candled through Berkefeld "N" filter.

*Methylene-blue* (Grübler).—Stock aqueous solution 1 in 250, steamed half an hour prior to use; diluted to 1 in 5000 with Locke-Lewis fluid freshly for each test. (All salts used were A. R. reagents (B.D.H.))

*Sterile vaseline.*

"Standard" toxin, B.8750 (0.5 per cent. phenol).—A toxin of  $\alpha$ -hæmolytic type prepared by combined use of modification of Parker's broth and Burnet's agar (Parish and Clark, 1932) from staphylococcus Wood 46.

"Standard" antitoxin, "K" (=B.8760) (0.3 per cent. T.K.B.).—Unconcentrated antitoxin (horse) of anti- $\alpha$ -hæmolytic type. (Both "standard" preparations were those recommended for use in the clinical investigation of anti-hæmolysin in human sera (Parish, O'Meara, and Clark, 1934).)

*Experimental staphylococcal filtrates.*—Prepared by the same method as "standard" toxin, B.8750.

*Experimental staphylococcal antitoxins.*—Rabbit, horse, and human.

*Leucocyte-suspension.*—Leucocytes obtained by intrapleural injection of aleuronate + starch suspension, whole technique being performed with sterile precautions. For each test (usually about six toxins or antitoxins) eight rabbits injected. Fur over the thoracic region removed by fine clippers, rabbit lightly anaesthetised with ether, skin treated with iodine, and incision made through skin, subcutaneous tissues, and superficial muscles in the thoracic region just below the scapula. Cannula pushed carefully between the ribs into the

\* It was found that these preservatives were not in themselves leucocidal at the dilutions used.

pleural cavity and 10 c.cm. of aleuronate + starch suspension injected. Needle withdrawn and incision covered with adhesive plaster. Eighteen hours later rabbits killed by intravenous injection of 10 c.cm. of air. Both pleural cavities opened with scissors, for, although injections made into one pleural cavity only, as good an exudate frequently found in the other. Non-hæmorrhagic exudates pipetted into tubes containing 10 c.cm. of 1 per cent. sodium citrate in saline; after pooling, centrifuged at low speed for 5 minutes, and leucocytes resuspended in Locke-Lewis fluid in boiling tube. Cells retain reducing power throughout the day if aerated at frequent intervals through pipette, and keep better at room temperature than at 37° C. Cell counts of suspensions were approximately 40,000 leucocytes per c.mm., about 92 per cent. being polymorphonuclear.

**Preliminary Test for Minimal Reducing Power of Leucocytes.**—Into a row of test-tubes (10 cm. by 1.0 cm.), 0.4, 0.35, 0.30, 0.25, 0.20, 0.15, 0.10, 0.05, and 0.00 c.cm. of leucocyte-suspension were pipetted, the volume in each tube being adjusted to 1.0 c.cm. with Locke-Lewis fluid. 0.1 c.cm. of methylene-blue 1 in 5000 was then added to each tube. The contents were thoroughly stirred with a wire loop, a vaseline seal being added finally. The tubes were incubated for 1 hour at 37° C. and the smallest amount of leucocyte-suspension to produce full reduction was noted. Twice this volume was used as the dose of leucocyte-suspension in the actual test.

**Titration of N.W.L. in Toxic Filtrates.**—"Doubling" dilutions of the toxin in Locke-Lewis fluid were made, the volume in each tube being 0.5 c.cm. The test dose of leucocyte-suspension was added, and the volume, if not then 1.0 c.cm., adjusted to that amount with Locke-Lewis fluid. The tubes were incubated for one and a half hours at 37° C., and 0.1 c.cm. methylene-blue was added to each. The contents were stirred with a wire loop, and each tube was sealed with vaseline and incubated for a further hour at 37° C., when readings were made. The minimal leucocidal titre was taken to be the least amount which produced complete leucocidal action—i.e., the amount present in the last tube in which the methylene-blue remained completely blue.

For purposes of comparison similar dilutions of "standard" toxin, B.8750, were included in each test series, as well as the following controls with methylene-blue: (a) leucocyte-suspension alone; (b) toxins alone, without leucocyte-suspension; and (c) leucocyte-suspension + uninoculated medium, which had been incubated and filtered as in the preparation of staphylococcal filtrates.

**Titration of Anti-N.W.L. in Antitoxic Sera.**—"Doubling" dilutions of the antitoxin to be tested were made in Locke-Lewis fluid, the volume in each tube being 0.25 c.cm. 0.25 c.cm. of "standard" toxin, B.8750, diluted 1 in 20, was added to each tube. The contents were then mixed, and incubated at 37° C. for half an hour. The test dose of leucocyte-suspension (see above) was added to each tube and the volume in each, if not then 1.0 c.cm., adjusted to that volume with Locke-Lewis fluid. The contents of the tubes were mixed and incubated at 37° C. for one and a half hours. 0.1 c.cm. methylene-blue 1 in 5000 was added to each tube. The contents were thoroughly stirred with a wire loop, each tube being sealed with vaseline and again incubated. It was found that the presence of serum so accelerated the reduction of methylene-blue by leucocytes that it was difficult to fix a definite time limit for this further incubation. In each test series were included therefore dilutions of "standard" antitoxin "K," and the whole test was read when dilution 1 in 400 of "standard" antitoxin showed complete reduction (white) and dilution 1 in 800 showed no reduction (blue). The end-point for each antitoxin was taken as the least amount which completely neutralised "standard" toxin, B.8750, diluted 1 in 20—i.e., in which complete reduction of methylene-blue occurred. Readings were usually "clear-cut" and easy to make after 20 to 30 minutes.

It has been customary, in the absence of a "unit" of anti-N.W.L., to express the potency of sera in terms of "standard" antitoxin "K."

**Hæmolytic Titrations.**—The minimal hæmolytic dose of staphylococcal toxins was determined by preparing a series of "doubling" dilutions, 0.5 c.cm. in each tube, and adding 0.5 c.cm. of saline to each. To determine (a) the  $\alpha$ -hæmolysin, 1.0 c.cm. of 2 per cent. washed rabbit

red cells was added to each tube, the contents being then mixed, and readings taken after one hour's incubation at 37° C. The minimal hæmolytic dose was taken as the least amount of toxin to produce complete hæmolysis; (b) the  $\beta$ -hæmolysin, 1.0 c.cm. of washed sheep cells was added to each tube, the contents being mixed, and readings taken after one hour's incubation at 37° C. and one hour at room temperature.

**Antihæmolytic Titrations.**—The method used was that described by Parish, O'Meara, and Clark (1934).

#### NEISSER-WECHSBERG LEUCOCIDIN (N.W.L.)

**Variability of Tests for N.W.L.**—It was regarded as important for the evaluation of quantitative leucocidin estimations to determine what variation in the minimal N.W.L. titre of any one toxin might occur when tested with different leucocyte-suspensions. The limits of titration of toxin, B.8750, in twelve different tests, varied from 1 in 400 to 1 in 50 (thrice 1 in 400, six times 1 in 200, twice 1 in 100, and once 1 in 50). The variation was not dependent on the test dose of the leucocyte-suspension nor on ageing of the toxin over a period of four months.

**Constancy of N.W.L. Production by One Strain of Staphylococcus, Wood 46.**—From the staphylococcal strain Wood 46 eight toxins, in addition to "standard" toxin, B.8750, were prepared by the routine method at different times on different batches of medium. Considerable amounts of N.W.L. were produced in all filtrates over a period of eight months, six having a minimal N.W.L. titre of 1 in 200 or more.

**N.W.L. Production by Differently Pigmented Colonies.**—In a few instances toxins prepared from differently pigmented variants of the same staphylococcal strain gave identical minimal N.W.L. titres—e.g., strain I., white and orange colonies, each 1 in 100; strain II., cream and orange colonies, each >1 in 200; strain III., white and orange colonies, each nil.

**Relationship of N.W.L. Production to Pathogenicity of Staphylococcal Strains.**—In all 33 filtrates were prepared. None of 7 toxins from strains from non-pathological sources contained N.W.L., whereas all of 26 toxins from strains from patients undergoing hospital treatment (for furunculosis, blepharitis, carbuncle, sycosis, breast abscess, osteomyelitis, or septicæmia) gave a N.W.L. titre varying from 1 in 25 to 1 in 200 or more.

**Relationship of N.W.L. to  $\alpha$ - and  $\beta$ -Hæmolysin.**—The relationship of N.W.L. to  $\alpha$ - and to  $\beta$ -hæmolysin (Bigger, Boland, and O'Meara, 1927; Glenny and Stevens, 1935) was studied by (a) tests of comparative thermostability; (b) quantitative comparison in filtrates; and (c) absorption tests.

(a) A toxin, Z.1815, containing both  $\alpha$ - and  $\beta$ -hæmolysin, which was prepared from the staphylococcal strain "Bigger albus A $\alpha$ ," and the control toxin, B.8750, containing  $\alpha$ -hæmolysin only, were heated for 30 minutes at 56° C. The N.W.L. and  $\alpha$ -hæmolysin were completely destroyed, but the  $\beta$ -hæmolysin titre was left unchanged. N.W.L. and  $\beta$ -hæmolysin are therefore not the same toxin.

Heating a toxin of  $\alpha$ -hæmolytic type for one hour at 50°, 70°, or 100° C. completely destroyed N.W.L. and  $\alpha$ -hæmolysin; heating the same toxin for one hour at 40° C. reduced N.W.L. and  $\alpha$ -hæmolysin in the same proportion—in two experiments to half their original titre, and in one to a quarter.

(b) A comparison was made of the N.W.L. and  $\alpha$ -hæmolytic titres of twenty-nine toxins prepared from different strains of staphylococci. In twelve of these neither N.W.L. nor  $\alpha$ -hæmolysin was detected, and in the remaining ones the titres ran roughly

parallel—i.e., where the N.W.L. titre was high the  $\alpha$ -hæmolysin titre was also high and vice versa. No toxin was found in which the one could be detected but not the other.  $\beta$ -hæmolysin was not found in any of these filtrates by direct titration.

(c) Absorption test using leucocyte-suspension macroscopically free from red cells showed that N.W.L. was absorbed by leucocytes, and that the  $\alpha$ -hæmolysin was also greatly reduced in amount. The experiments were not completely satisfactory because of technical difficulties; moreover, the red cells used for the titration of hæmolysin were possibly a more sensitive indicator than leucocytes, of any toxin which remained unabsorbed.

Absorption tests have been attempted by other experimental workers, but usually with inconclusive results (see Neisser and Wechsberg, 1901; Weld and Gunther, 1931).

#### NEISSER-WECHSBERG ANTI-LEUCOCIDIN (ANTI-N.W.L.)

*Accuracy of the Titration.*—It was thought necessary for the evaluation of subsequent results to determine what variation in titre of the same sample of antitoxin might occur from test to test. For this purpose 5 antitoxins (4 from immunised horses and 1 from an unimmunised rabbit) were tested on two different occasions and it was found that a difference in titre of 100 per cent. either greater or less may occur in successive tests on the same sample of antitoxin. In view of the small volume, 0.25 c.cm., in which the dilutions were made and the complicated nature of the test this discrepancy is not surprising.

#### *Anti-N.W.L. and Anti- $\alpha$ -hæmolysin Titres of 66 Sera. Values in Terms of "Standard" Serum "K"*

No.	Serum.	Anti-N.W.L.	Anti- $\alpha$ -hæmolysin.	No.	Serum.	Anti-N.W.L.	Anti- $\alpha$ -hæmolysin
1	Normal human.	0.005	0.003	43	'Immune' rabbit.	0.01	0.01
2		0.01	0.012	44		0.02	0.015
3		0.015	0.015	45-47		0.08	0.076
4		0.02	0.012	48		0.25	0.171
5		0.04	0.042	49			
6-7		0.02	0.015	50	Normal horse.	0.08	0.05-0.07
8-15	'Immune' human.	..	0.022	51	'Immune' horse.	0.133	0.125
16-18		..	0.034	52-54		0.5	0.46
19-21		..	0.051	55-56		0.66	0.66
22-25		0.04	0.034	57		1.0	0.8
26		..	0.051	58		..	2.0
27		..	0.076	59-60		1.3	1.8
28		0.08	..	61-63		4.0	2.0
29-41		Normal rabbit.	Nil.	Nil.		64-65	10.0
42	0.02		0.022	66	..	5.3	

'Immune' signifies only that the samples were obtained after a course of immunising injections of toxin or toxoid.

*Relationship of Anti-N.W.L. and Anti- $\alpha$ -Hæmolysin in Normal and "Immune" Sera.*—A series of normal and "immune" sera from human beings and animals were tested for anti-N.W.L. and anti- $\alpha$ -hæmolysin, both titres being expressed in terms of "standard" antitoxin "K," which contains 150 international units of anti- $\alpha$ -hæmolysin per c.cm. (see Table). The majority of the antihæmolysin titres were tested independently by other workers, using the method introduced by Parish, O'Meara, and Clark (1934). (In the case of human sera, Dr. D. Stark Murray has kindly allowed me to use his figures.)

Of the 66 sera titrated for anti-N.W.L. and anti- $\alpha$ -hæmolysin, 13 contained neither antibody. The

remaining sera in practically all cases showed agreement in titre for the two antibodies; where discrepancies arose these fell within the limits of error of the tests.

#### CONCLUSIONS AND SUMMARY

(1) A modification of the Neisser and Wechsberg technique for the estimation of staphylococcal (Neisser-Wechsberg) leucocidin (N.W.L.) and anti-leucocidin (anti-N.W.L.) is described, and the accuracy of the tests discussed. (2) One strain of staphylococcus, "Wood 46," produced N.W.L. of high titre consistently over a period of eight months. (3) Thirty-three filtrates were prepared from different staphylococcal strains. None of 7 toxins prepared from strains derived from non-pathological sources contained N.W.L., whereas 26 toxins prepared from strains isolated from pathological lesions yielded N.W.L. varying in titre from 1 in 25 to 1 in 200 or more. (4) N.W.L. is thermolabile at 56° C., and is largely destroyed by heating to 40° C. for one hour, being identical in this respect with  $\alpha$ -hæmolysin and differing from  $\beta$ -hæmolysin which is thermostable at 56° C. (5) Of 29 toxins prepared from different strains of staphylococci, 12 contained neither N.W.L. nor  $\alpha$ -hæmolysin. In the remaining 17 the titres ran roughly parallel—i.e., where the N.W.L. titre was high, the  $\alpha$ -hæmolysin titre was also high and vice versa. In no toxin was the one found without the other. (6) Absorption of N.W.L. and  $\alpha$ -hæmolysin by leucocytes gave inconclusive results. (7) Sixty-six sera from man, rabbits, and horses, normal and "immunised," had in nearly all cases corresponding titres of anti-N.W.L. and anti- $\alpha$ -hæmolysin, expressed in decimal fractions of "standard" antitoxin "K." In the few exceptions the titres fell within the limits of error of the tests. (8) It is suggested that N.W.L. and  $\alpha$ -hæmolysin of staphylococcal filtrates prepared by the method referred to in this paper are identical, and that anti-N.W.L. and anti- $\alpha$ -hæmolysin are the same antibody.

My thanks are due to Dr. H. J. Parish and Dr. R. A. Q. O'Meara for their kind help with this work; to Mr. A. T. Glenny and Miss M. F. Stevens for supplying "immune" horse sera; and to Dr. D. Stark Murray for kindly supplying human sera and allowing me to use the results of his antihæmolysin titrations.

BOND-STREET WARD AT THE MIDDLESEX HOSPITAL. The Bishop of Willesden, on April 23rd, dedicated the Bond-street ward at this hospital. Approximately 200 in-patients from Bond-street firms are treated every year in the hospital, and a much larger number of out-patients. Prince Arthur of Connaught said that Bond-street had its full sense of that civic pride which led centuries ago to the foundation of the great city companies with their traditions of service and charity. The ward is set aside to provide treatment for accidents and fractures.

## LATE ETHER CONVULSIONS

A STUDY BASED ON FOUR CASES

By R. F. WOOLMER, B.M. Oxon.

SENIOR RESIDENT ANÆSTHETIST TO ST. THOMAS'S HOSPITAL, LONDON; AND

STEPHEN TAYLOR B.Sc., M.B. Lond.

HOUSE PHYSICIAN TO THE MEDICAL UNIT AND LATE RESIDENT ANÆSTHETIST AT THE HOSPITAL

CONVULSIONS occurring during deep ether anæsthesia were first described by Wilson, and they are now recognised as one of ether's most serious immediate dangers. Fortunately they are rare; the longest series seen and recorded by one man is Pinson's 15 cases. The mortality is about 50 per cent.; two of our four cases were fatal. Each showed the characteristic clinical picture, with minor variations, but each was treated in a different way. All occurred in the theatres of St. Thomas's Hospital during 1935, and one or other of us was present on each occasion.

### TYPICAL CLINICAL PICTURE

The patient is a child or young adult with pyrexia, usually due to some acute septic condition. The theatre is overheated. Atropine has been given and the dose may have been excessive. The patient is deeply anæsthetised with ether, the pupils being dilated and inactive to light. The colour is, as a rule, good, and oxygenated ether is sometimes being given. The eyelids start to twitch, then the face, and the convulsions become general. In the immediately fatal cases, after 5–10 mins. of convulsions the respiration ceases, the patient goes blue, and the heart stops; in other cases, the convulsions stop, but the patient dies later from cardiac failure; alternatively, recovery may follow the cessation of the convulsions.

Ether convulsions have to be differentiated from ether clonus, which occurs in the early stages of anæsthesia. Clonic twitching starts in the limbs and may become very violent; it ceases as the anæsthesia deepens. True convulsions occur only after full anæsthesia has been established, and the term "late ether convulsions" is used to emphasise this difference.

### DESCRIPTION OF CASES

For comparison, the essential features of our cases are given in the Table.

In Case 1 oxygenated ether was being used; the convulsions were recognised the moment they started and were easily stopped. A subsequent ether anæsthesia was given without convulsions. McDonald, Willway, and Ashworth have described similar cases.

In Case 2 a second dose of atropine was given owing to delay with the previous operation. The day temperature was excessive, and the anæsthetist actually remarked upon the possibility of convulsions before starting the anæsthetic. As the surgeon needed complete relaxation however, open ether was used. So far as we know, this is the first case of ether convulsions in which the anæsthesia has been successfully continued with ether—and moreover ether from the same bottle.

In Case 3, as in Case 1, a pyrexial patient had a large dose of atropine on a hot day. All the usual methods of stopping the convulsions failed, and this is, we think, the first time Evipan Sodium has been used. Its success in stopping the convulsions justifies its being tried in the future.

In Case 4 the day was again hot. The heart stopped, but was successfully restarted by cardiac massage, and it beat strongly as long as artificial respiration was continued. All attempts to start spontaneous respiration, however, failed and ventilation was maintained by means of the Drinker automatic respirator. This kept the patient alive for 3½ hours, before the heart finally stopped. We therefore think the automatic respirator worthy of further trial.

### ETIOLOGY

In the past several theories as to the cause of ether convulsions have been advanced.

*Impurities.*—Wilson found acetaldehyde and peroxides in the ether he was using when convulsions occurred, and not in other samples of ether. Walton had a similar experience. Sykes, however, records a case where acetaldehyde was absent, and peroxides amounted to only 0.05 part per million of ether. Ross Mackenzie describes seven cases where the ether was carefully analysed. The largest amount of peroxides was 0.65 part per million, while the largest amount of acetaldehyde was 0.05 part per million; the toxic dose of each is ½ per cent., so that it is almost inconceivable that these impurities were the cause of the convulsions. Our case (No. 2), where the same ether was used after the convulsions had ceased, with no ill-effect, is strongly suggestive that ether, per se, or its impurities, is not to blame.

*Idiosyncrasy.*—Hadfield and Kemp have thought that some patients have an "ether convulsion diathesis." Four cases have already been mentioned where ether has been used successfully after convulsions had occurred at previous operations. Our Case 2 is even more important in discounting the suggestion of a diathesis.

*Congestion of the Rolandic area from jugular obstruction* is suggested by Hewer, who advises raising the chin to relieve it. In Case 2 the manoeuvre of lowering the chin was tried and the convulsions immediately became worse. Rolandic congestion may therefore be of some significance.

*CO<sub>2</sub> accumulation* is believed by Pinson to be the cause. Actually CO<sub>2</sub> is a most effective agent in treatment.

*Atropine overdosage.*—Hornabrook suggested this. It occurred in two of our four cases, and is a factor frequently but by no means always present.

*Sepsis.*—This too is often but not invariably present. Enormous numbers of septic cases have ether anæsthesia without convulsions.

*Over-oxygenation.*—Mennell thought this might be the primary factor. It was present in one of our cases, but another was definitely cyanosed. Cyanosis has several times been described as a precursor of ether convulsions.

It is obvious that none of these views is at all satisfactory. We suggest that ether anæsthesia upsets the normal heat-regulating mechanism of the body and we wish to support Dickson Wright's hypothesis that *heat-stroke* may play a big part in the aetiology of ether convulsions. Our evidence is as follows: (1) In three of our four cases the day temperature was excessively high. Hadfield's cases at St. Bartholomew's Hospital, London, all occurred during the summer. (2) The association of ether convulsions with pyrexia is well known. All our cases were pyrexial, and the post-operative temperatures were high. Temperatures during the convulsions were unfortunately not taken. Mackenzie records a case where, during the convulsions, the

temperature was 108° F. Cold sponging lowered the temperature and stopped the convulsions. When the patient was back in bed the temperature rose to 106.8° F., and convulsions started again. Once more cold sponging proved successful, though the patient died later. (3) By stopping sweating, an overdose of atropine tends to reduce heat loss. Its association with ether convulsions has already been mentioned. (4) The hyperpnœa which CO<sub>2</sub> produces, not only removes ether but also heat from the body. It has already been shown that ether itself is probably not the cause of the convulsions. The beneficial effect of CO<sub>2</sub> in relieving convulsions may well be due to its action in accelerating heat loss. (5) In 11 of Pinson's 15 cases the convulsions followed

the use of the ether bomb, the principle of which was to deliver superheated ether vapour into the patient. (6) Bull describes the case of an Arab woman who had convulsions under chloroform. The heat at the time was too great for the use of ether. (7) Convulsions are one of the manifestations of heat-stroke. Willcox describes the heat hyperpyrexia form of heat-stroke as follows: "The onset may be sudden, with rapid rise of temperature, coma and convulsions . . . the skin is hot and dry, and the face flushed and cyanosed . . . the pupils are dilated . . . fibrillary twitchings of the muscles and convulsions usually occur . . . and pulmonary œdema is a terminal event." This description would do very well for an ether convulsion.

## FOUR CASES OF ETHER CONVULSIONS

	CASE 1.	CASE 2.	CASE 3.	CASE 4.
Sex and age ..	Female, aged 14.	Female, aged 6.	Male, aged 39.	Female, aged 20.
Disease .. ..	Acute mastoiditis.	Acute appendicitis.	Acute appendicitis in a case of obstructive jaundice.	Acute appendicitis.
Day temp. ..	57° F.	77° F.	84° F.	69° F.
Patient's temp.— Before operation	101.5° F.	100.8° F.	103° F.	102° F.
After operation	103° F.	104.2° F. (rectal)	104° F.	—
Atropine dosage (gr.).	1/100	1/100 + 1/150	1/75	1/100
Anæsthetic ..	Clover→ open ether→ ether and oxygen by Mennell's bottle.	Ethyl chloride→ open ether.	Ethyl chloride→ open ether.	Clover→ open ether.
State under anæsthetic .. ..	Good. No cyanosis.	Flushed→ Cyanosis (O <sub>2</sub> given). Pulse-rate 120→150→180.	Fair. No cyanosis. Difficult gangrenous appendix removed.	—
Duration of anæsthesia before onset of convulsions (mins.)	10	12	65	50
Duration of convulsions (mins.)	3	5	25	10
Treatment of convulsions.	Ether stopped; O <sub>2</sub> and CO <sub>2</sub> given.	Ether stopped; O <sub>2</sub> and CO <sub>2</sub> given. Dropping chin forwards made convulsions worse.	Ether stopped; O <sub>2</sub> and CO <sub>2</sub> given: no effect. Chloroform: no effect. Cyanosis increasing. Trachea intubated, head raised. Colour improved, but convulsions continued. Amyl nitrite, then chloroform again. Convulsions and pulse worse. Adrenaline 1/10 intravenously. Evipan sodium 8 c.cm. intravenously.	Ether stopped. O <sub>2</sub> and CO <sub>2</sub> given.
Result of treatment of convulsions, and details of further general treatment.	Convulsions ceased after 2 minutes' hyperpnœa.	Convulsions ceased after 4 mins.' hyperpnœa. Anæsthesia was by then quite light.	Convulsions ceased within 2 mins. of injection of evipan. Operation quickly concluded. Pulse-rate 146, quality poor, on leaving theatre.	After 10 mins.' convulsions, heart and convulsions stopped. Trachea intubated and artificial resp. with McKesson's apparatus started. Adrenaline (4 c.cm. in all) given. Cardiac massage twice re-started heart. No spontaneous resp. after initial failure. After 1½ hours' artificial resp. with the McKesson, she was transferred to Drinker respirator.
Anæsthesia during rest of operation (and duration).	Chloroform and O <sub>2</sub> , by Junker's inhaler, for 40 mins.	Open ether, from the same bottle, with O <sub>2</sub> for 20 mins.	None needed.	None needed.
After-treatment.	Nil.	Nil.	In spite of cardiac stimulants, patient died 34 hours after operation without recovering consciousness.	After 3½ hours in the Drinker respirator, patient died from cardiac failure.
After-history ..	Developed streptococcal septicæmia and lateral sinus thrombosis; 13 days after first op., lateral sinus opened and jugular tied under prolonged open ether anæsthesia. No convulsions; uneventful recovery.	Rapid uneventful recovery.	P.M.: Extensive carcinoma of liver, dilatation of heart, and severe pulmonary œdema.	P.M.: Terminal dilatation right side of heart. Nothing else abnormal.

## PROPHYLAXIS AND TREATMENT

In the belief that the heat-stroke hypothesis provides the best explanation which has so far been offered for the aetiology of ether convulsions, we advise appropriate means of prophylaxis and treatment.

The anaesthetist should limit pre-operative atropine to gr. 1/150 in children and young people with acute septic diseases and a temperature of over 100° F., especially in hot weather, and he should avoid excessive coverings, above all mackintoshes, for such patients in the theatre. He must be constantly on the watch for the first twitch of the eyelids or mouth in these patients, and, if it occurs, he must apply treatment immediately.

To treat the convulsions, CO<sub>2</sub> and oxygen should be given at once. If they do not cease within a minute, evipan sodium should be injected intravenously. While preparing the evipan, cold sponges and ice should be applied to the body and face. If necessary,

the trachea should be intubated. To combat cardiac failure, adrenaline and Coramine should be given, and for respiratory failure, artificial respiration—manually, or mechanically by means of the McKesson machine and the Drinker respirator or Bragg-Paul pulsator; the latter is probably preferable, as the Drinker apparatus tends to conserve heat.

## CLINICAL AND LABORATORY NOTES

ANEURYSM OF THE SPLENIC ARTERY  
SIMULATING CHOLECYSTITIS

By S. E. OSBORNE, L.M.S.S.A.

RESIDENT SURGICAL OFFICER, WORTHING HOSPITAL, SUSSEX

ANEURYSMS of the splenic artery, although uncommon, are not as rare as would at first sight be expected, and Anderson and Gray in 1929 were able to collect 58 recorded examples.<sup>1</sup> The present case has certain unusual features.

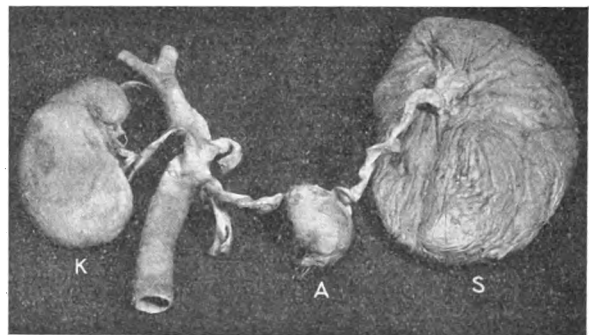

Miss A, aged 43, a cook, was sent to the Worthing Hospital as a case of acute cholecystitis. She gave a history that apart from pneumonia and influenza, her only illness was in 1909, 27 years previously, when an operation was performed for suspected disease of the gall-bladder. The operation scar is a paramedian supra-umbilical one: evidently the gall-bladder was inspected and found to be normal and the appendix removed through this high incision.

The present symptoms began six years ago, when the patient first complained of abdominal pain coming on in attacks at infrequent intervals, colicky in nature, beneath the right costal margin, radiating through to the right shoulder and aggravated by stooping. A feeling of fullness was noticed in the epigastrium, discomfort after meals, and very troublesome flatulence. There was continuous nausea but only occasional vomiting. Fatty foods were not tolerated and brought on pain. Occasionally after the attacks there was slight jaundice, but the urine was not noticed to be deeply coloured and clay-coloured stools were not a feature.

*Examination.*—The patient was stout, very nervous, and apprehensive. Temperature, 98·4° F.; pulse-rate, 96; respirations, 20. There was some tenderness over the gall-bladder on palpation, and slight tenderness in the epigastric region, which persisted for some time afterwards. The heart and chest were normal. No other abnormalities were to be found, and the diagnosis of gall-stones with cholecystitis was made. An opaque cholecystogram showed that the gall-bladder filled and emptied normally and no stones were demonstrated.

*Operation.*—Under ethyl chloride and ether anaesthesia the abdomen was opened through a midline incision and the gall-bladder inspected. Many adhesions were present, but no gall-stones were felt either in the gall-bladder or in the common bile-duct. A large whitish-grey round tumour then came into view, lying in the

gastrohepatic omentum above the stomach and midway along the lesser curvature of the stomach. The tumour was firm, fluctuant, and about the size of a tangerine orange. The walls were calcareous and cracked when pressed. No pulsation was seen or felt, and the tumour was thought to be a pancreatic cyst, and was incised. Blood escaped with considerable force and the stream was seen to pulsate. The diagnosis of an aneurysm was at once obvious. By firm pressure on the aorta with the fingers it was possible to control the hæmorrhage. The position of the aneurysm was such that removal was impossible, and an attempt to sew up the incision in the aneurysm failed because the walls were so calcareous

A photograph of the spleen (S), aneurysm (A), and kidney (K) dissected post-mortem.

that the stitches cut out as soon as they were inserted. The patient had by this time lost a considerable amount of blood, and as her condition was giving rise to some anxiety, the wound in the aneurysmal sac was closed by two pairs of curved artery forceps, which were left in situ. The abdominal wound was closed and the patient returned to bed.

*Post-operative treatment.*—The patient was given the usual restoratives and a blood transfusion of 26 oz., and on the following day her general condition had improved. On the third day the clamps were removed. On the ninth day after the operation she was taking food well and did not complain of pain or feeling unwell. There was some serous discharge from the wound. At 12.20 A.M. a sudden severe secondary hæmorrhage took place, and in spite of blood transfusions, morphia, and hæmoplastin serum the patient collapsed and died at 10.15 A.M.

*Pathology.*—Post-mortem examination revealed a large and flabby heart with excess of fat. The aortic valves were normal and free of vegetations. There was no

<sup>1</sup> Anderson, W., and Gray, J.: *Brit. Jour. Surg.*, 1929, xvii., 267; see also Brockman, R. St. L.: *Ibid.*, 1930, xvii., 692.

atheroma of the aorta. About a third of the way along the splenic artery from its origin at the celiac axis was a thick-walled partly calcified aneurysm, the size of an egg and containing laminated blood-clot, firmly adherent to the pancreas and splenic vein. The artery distal of the aneurysm was very tortuous. The spleen was very large, about three times normal in weight and size (see Figure). The liver was fatty, the gall-bladder was normal and contained no stone.

The interest in this case is that the symptoms resembled those of a cholecystitis with gall-stones. In the cases previously reported the symptoms have simulated those of a gastric and duodenal ulcer very closely in the majority of cases and the reference of the pain to the gall-bladder area is unusual. It is possible that the opening of the abdomen for suspected gall-bladder trouble 27 years previously marked the commencement of the formation of the aneurysm. A point in the differential diagnosis is the alteration of the intensity of the pain with posture, suggesting rather strongly a vascular lesion. As in the other reported cases there was no history of trauma. The Wassermann reaction was negative, and there was nothing to suggest a possible cause for the formation of the aneurysm.

### ACUTE APPENDICITIS IN AN INFANT RESEMBLING INTUSSUSCEPTION

By F. H. COLEMAN, M.B. Camb., M.R.C.P. Lond.

RESIDENT MEDICAL OFFICER, THE QUEEN'S HOSPITAL FOR  
CHILDREN, LONDON, E.

THE following case is recorded because the patient was unusually young and because there were symptoms suggestive of intussusception:—

A girl, aged 5 months, was brought to hospital by her mother, who said that for nine hours the baby had had screaming attacks, associated with drawing-up of the legs; the attacks had lasted a few minutes, the intervals between them being spent in sleep. At the onset of the attacks the mother had noticed the passage of bright blood and mucus per rectum; this also occurred just after arrival at the hospital. The baby was bottle-fed, but had not taken anything that day; there had been one moderate-sized food vomit. A fortnight previously there had been an alleged attack of broncho-pneumonia, treated at home.

The baby appeared to be fairly well nourished and not very ill. The temperature was 100.2°F. and the pulse-rate 176. Two more or less typical screaming attacks occurred during the examination. There were numerous coarse rhonchi in the chest, and the abdominal examination was negative, save for a suggestion of emptiness in the right iliac fossa. A rectal examination revealed no blood on the examining finger, nor any tumour.

The diagnosis was believed to be intussusception, although the possibility of the case being one of Sonne dysentery troubled us considerably, especially as an epidemic of the latter was raging in the neighbourhood. After admission the screaming attacks continued and it was thought advisable to make an examination under anaesthesia. The result of this was that we could just feel a lump deep down under the right costal margin, which decided us to carry on and open the peritoneal cavity. On opening this, a certain amount of free fluid was found; no intussusception was present, but the distal third of the appendix was very acutely inflamed. Apparently the palpable lump was accounted for by the right kidney, which had prominent foetal lobulation. The appendix was removed, and the operation was followed by very rapid and entirely uneventful recovery, the stools having a normal appearance two days after operation. A stool, passed the day after admission, was examined bacteriologically, and found to contain mucus, but no non-lactose-fermenting organisms.

This case leads one to wonder whether appendicitis is not a far commoner disease of early childhood than is usually appreciated. Simpson-Smith<sup>1</sup> states that in a series of 311 cases of appendicitis at the Hospital for Sick Children, Great Ormond-street, exploration of the abdomen revealed in 65 per cent. an appendix which was either gangrenous, perforated, or necrotic in an abscess cavity; and this suggests an earlier attack in at least a proportion of these.

The cases which actually have been diagnosed in infancy have often been discovered accidentally whilst operating for another condition. Thus Ham<sup>2</sup> reports the case of an infant 12 days old, with one day's history of swelling of the right side of the scrotum, associated with one vomit, which was found at operation to have a scrotal hernia containing the caecum and a gangrenous appendix. Pope<sup>3</sup> also reports the case of a baby 3 weeks old, with five days' history of swelling and inflammation of the penis and scrotum, and a temperature of 102.2°F., diagnosed as acute orchitis and treated by incision and drainage. A sinus formed soon afterwards, and this was followed by a hernia at that site. Two years later an operation for radical cure of a right scrotal hernia was performed, and the appendix was discovered adherent to the sinus and showing evidence of old inflammation, both testes being perfectly normal. The case here reported falls into the same category, since the true nature of the disorder was not suspected.

I am much indebted to Mr. D. W. C. Northfield, under whose care this patient was admitted, for permission to place the case on record.

### TWO CASES OF RETENTION OF URINE IN WOMEN

By H. P. WINSBURY-WHITE, M.B. Edin.,  
F.R.C.S. Eng.

SURGEON TO ST. PAUL'S HOSPITAL FOR GENITO-URINARY  
DISEASES, LONDON

THESE cases are of particular interest for two reasons: one is the prominence of the chronic inflammatory element in the aetiology, and the other is the satisfactory result of resection of tissue from the bladder neck, performed by the high-frequency cutting method.

CASE 1.—The first patient, a single woman aged 30, was first seen in December, 1934. She complained that she was in the habit of holding her water for two or three days, after which it was passed spontaneously. She gave the following history. After appendicectomy in 1928 a catheter had to be passed daily for nearly three weeks, but micturition became normal on her discharge from hospital. It remained thus until Christmas, 1933, when she was confined to bed for three weeks with a bruised shoulder and abdominal pain resulting from a motor-car accident, and resumed her former habit of holding her water for three days. On discharge from hospital normal micturition again returned, and it was maintained until August, 1934, when, after a cold in the head and chest, she returned to her old practice of urinary retention for two and three days at a time. This was the state of affairs when I saw her in December, 1934.

At this time the laboratory report on the urine showed it to be sterile, nor were any pus cells or any chemical abnormalities detected. The blood Wassermann reaction was negative. While interrogating the patient it was

noticed that she suffered from spasmodic twitchings of the face and one or other shoulder. She informed me that these had come on after the motor-car accident about a year before. On examining the vulva, swelling and redness were noted in connexion with the Skene's gland and there were also some small superficial ulcers surrounding the orifice of the introitus. These lesions were investigated carefully and the possibility of syphilis was thereby eliminated. A small introitus prevented a view of the cervix at this time. Cystoscopy showed oedema at the internal urinary meatus and a raising of the posterior lip of this structure above the floor of the trigone. Intravenous urograms failed to reveal any renal abnormality, and it was particularly noted that there was no evidence of back pressure on the kidneys from the distended bladder. The blood-urea was 27 mg. per 100 c.cm.

After six months' treatment with fortnightly and monthly urethral dilatations, the patient improved to the extent that she was able to empty her bladder once in 24 hours. At this stage I admitted her to hospital for examination of the pelvic organs under an anaesthetic and for treatment to the bladder neck. On bimanual vaginal examination no abnormality was detected but inspection showed erosion of the cervix. I therefore dilated and cauterised the cervix. With the McCarthy electrotome I then removed a piece of tissue from the floor of the internal urinary meatus measuring  $\frac{1}{2}$  by  $\frac{1}{2}$  inch. Microscopical examination of the excised tissue showed a certain amount of round-celled infiltration and fibrosis of the part. The result of this treatment was that the patient passed water twice in 24 hours, but a few weeks after discharge from hospital she returned to her old habit of micturating once only in 24 hours. Twitches of the face and shoulder, however, disappeared after this treatment and have not subsequently returned.

Four months after the operation I again admitted the patient to hospital and removed another small piece of tissue from the bladder neck. Since this time, which is now about five months ago, she has passed her water regularly two and three times a day.

CASE 2.—My second patient was a married woman of 44, who had had three children, now aged 22, 17, and 10. She had had an attack of complete retention of urine three weeks previously, which had to be relieved by catheterisation. The history of this complaint goes back 22 years to the time when she had a similar attack after her first confinement, and there have been several such crises at long intervals in the intervening period. Frequency of micturition has always followed, and when I first saw her, although she was able to hold her water as long as four hours during the day, she found it necessary to rise four times during the night. Her periods have been somewhat irregular.

On examination a tendency to procidentia was evident. A ring pessary was being worn for this. The cervix appeared somewhat hypertrophied but otherwise normal. Cystoscopy showed the retrotrigonal pouch which is characteristically noted with vesicovaginal displacement. Both kidneys were functioning well as indicated by the excretion of indigo-carmin. The posterior margin of the internal urinary meatus was seen to be somewhat raised above the level of the trigone. A laboratory report on the urine indicated the presence of *Bacillus coli*.

I admitted the patient to hospital and with the McCarthy electrotome removed a single piece of tissue about  $\frac{1}{2}$  by  $\frac{1}{2}$  inch from the floor of the internal urinary meatus. The patient was sent back to bed with an indwelling catheter for four days, during which time daily vesical irrigation was carried out. Microscopical examination of the tissue removed showed a well-marked fibrous change and round-celled infiltration, thus making it clear that chronic inflammation was the cause of the condition at the bladder neck.

When the patient was seen by me five months after her operation, cystoscopy showed a trigone which was healthy in appearance and which shelved perceptibly into the posterior urethra. There was no pus in the urine, and though coliform bacilli were still present on culture, she now stated that she had no urinary symptoms and that she no longer found it necessary to rise at night.

## MEDICAL SOCIETIES

### ROYAL SOCIETY OF MEDICINE

#### SECTIONS OF PSYCHIATRY AND THE STUDY OF DISEASE IN CHILDREN

A JOINT meeting of these sections was held on April 21st at 8.30 P.M. with Dr. H. J. NORMAN in the chair.

Dr. WILLIAM MOODIE opened a discussion on

#### Enuresis

He said that his communication resulted from a survey by Miss Robina Addis of the London Child Guidance Clinic. All possible information from the records had been collected to combat our depressing ignorance of the subject. Enuresis was not a disease by itself, nor necessarily a symptom of mental maladjustment. It occurred in all types of child, all classes, all environments, and after all kinds of training. Many inaccurate statements were made about it, and facts and figures were needed. A comparison had been made between the non-enuretic and the enuretic children, including those not specially sent for this symptom. Enuresis was present in 314 out of 1705 children (18.4 per cent.). When the cases treated by local doctors, or merely slapped at home, were added, the extent of the problem became evident. Boys predominated, the proportion of boys to girls with enuresis being 3 to 2, whereas the proportion of boys to girls among all the children

examined was 2.2 to 2. As regards intelligence the enuretics fell into two groups, high and low normals. There were less enuretics in the lower intelligence groups, and even at the idiot level only 2 out of 34 were enuretics. Enuresis did not depend on intelligence, so that attempts should be made to train imbeciles in toilet habits. The non-enuretic group increased in numbers between 10 and 14 years, whereas the enuretic reached its maximum from 8 to 10 years, decreasing with the onset of puberty. There was a definite relationship to sex difficulties, many cases clearing up when tension about sex was relieved.

A special analysis of 30 cases revealed some interesting facts. Of 19 boys, 8 and of 11 girls, 4 were cured (40 per cent.), the criterion of cure being six months without a wet bed. A change from home environment broke the vicious circle, but there was no factor of recovery common to all. A detailed study of symptoms was made as a possible guide to treatment. Results suggested that those who wetted regularly were more likely to clear up than those who wetted in bouts. The condition was attributed to "nerves," ill-health, rows at home, the East wind, or to a combination of several of these. Of 15 who showed both diurnal and nocturnal enuresis 4 cleared completely, while 5 became clean at night. A history of definite onset was obtained in 8 cases between the ages 2 and 9 years, nocturnal in 3, both nocturnal and diurnal in 5. Both types seemed equally likely to break down after control appeared

to be established. Where there was also incontinence of fæces the patient did better than was commonly anticipated, perhaps because "this can't go on" was said more firmly by parents and doctors than when enuresis alone was the trouble. In not one case was waking at night or restriction of fluids of value; these measures might do harm as a nightly reminder to the child that he was expected to wet. Habit training could be classed as good or bad; 6 recovered out of 17 good cases, and the same number out of 13 bad cases. Home conditions, birth weight, method of feeding had no demonstrable influence. The symptom appeared in the period of debility following illness, especially between the ages 2 and 3. Of 21 successful in school only 7 recovered, and cases were cured while still failing at school.

Dr. Moodie considered next the type of child in the series of 30 cases; 8 were timid, 7 withdrawn, 12 sociable, and 3 defiant, the last failing to recover. Analysis of pedigrees pointed to a high incidence of enuresis among siblings and relatives. Allergic symptoms were frequent, and possibly family trees were richer in neurotic and psychotic types. Although these figures had been worked out with great labour, they left us much where we were. In conclusion he confessed that the psychological explanation was by no means the whole story. Some physiological factor must be present also. There were chemical factors, bacillurias, fine balances between the various parts of the nervous system, anatomical anomalies not yet understood, and acting with them was the psychological factor.

Dr. REGINALD MILLER said that enuresis should be limited in this discussion to cases of urinary incontinence of functional origin. The condition either continued from infancy—"congenital" type, or arose after control had been established—"acquired" type. Males predominated and there was no enuresis problem in schools for girls as there was in schools for boys. Sometimes diurnal or fæcal incontinence coexisted. He stressed the importance of differentiating the factors that started enuresis from those that perpetuated it. The short interval between sleep and incontinence contrasted strangely with the large amount passed, which might be about three mattresses full. The automatic emptying of the bladder depended not only on the amount of urine, but on the rapidity of its accumulation. If fluid by mouth was withheld, it was attracted from the tissues, the result of some vaso-motor or secreto-motor activity. The influence of hot and cold weather emphasised the importance of rapidity of secretion. He had seen the symptom too frequently cease in summer, relapse in winter, and finally clear in the following summer, to be in any doubt on this matter, despite Dr. Moodie's disagreement. In psychological make-up bed-wetters were singularly like non-bed-wetters. Two types could be distinguished, the neurotic and the phlegmatic. The neurotic was emotional, had disturbances of conduct by day, with diurnal enuresis and perhaps fæcal incontinence; sleep was restless and disturbed, acquired enuresis was common, the proportion of girls high, and psychological disturbances maximal. In the phlegmatic type the reverse held in all particulars. There was no great difference in numbers in the two groups. The wet phlegmatic differed only from the dry phlegmatic in the regularity of his bed-wetting. Dr. Miller's contention that psychologists saw a selected group of the neurotic, emotional type was confirmed by the high proportion of females,

acquired cases, and cases incontinent of fæces in their reported series. The phlegmatic type presented the real problem. Many cases could be cured by drugs, and that this was not a form of suggestion was borne out by the failure of circumcision, undoubtedly a much stronger form, and the effect of altered doses for better or worse. Belladonna and strychnine were very successful, and if all cases were associated with nervous instability there could hardly be a less suitable mixture. There was no doubt that psychologists had got away with the disorder enuresis, but Dr. Miller urged that the psychological disturbances induced by enuresis in child and parents should be distinguished from the cause of the enuresis. The anxiety state resulting from enuresis could not also be its cause. The phlegmatic boy did not care; he knew that the condition had existed from infancy, occurred when he was fast asleep, and he had the sense to know that he was not to blame. He accustomed himself to bed-wetting just as he might to being fat or red-haired or called Ramsbottom. The psychological aspects of enuresis were more epiphenomena than causal. To his mind the cause was still obscure, and he felt that the fraternal cordiality between the two sections could be re-established if they united in declaring that they did not know the cause of enuresis.

Dr. D. W. WINNICOTT claimed that psycho-analytic discoveries had made possible further understanding of enuresis, besides the treatment of individual cases. Enuresis might be normal or an early symptom of dementia præcox, but usually it was part of a difficulty in emotional development, associated with other symptoms. Frequently the symptom ceased without treatment, or after medicinal treatment, sometimes reappearing at puberty as nocturnal emissions. He discussed the possible explanations of the act from the psycho-analytic point of view. The important element was the unconscious fantasy, the principal emotions expressed being love, hate, and reparation. Anxiety was always related to the fantasy. The infant used bodily pleasures to deal with anxieties, and in order to stand pain and frustration. The mother, training the baby to be clean, could from the baby's point of view be a creator of evil, turning love into anger inside him. Early induced cleanliness might be followed by refusal to use the pot at 1 to 1½ years, a real danger of modern teaching. Control of sphincters was only stable when it resulted from the child's unconscious identification with clean and self-controlled parents. The best advice to give mothers was to avoid conscious efforts at training, merely to give the opportunity to be clean. Clean babies normally become dirty at times, and then no special effort should be made. It was wiser to leave alone the mother who did not ask for advice, acted on intuition, and might well know more than the doctor how to bring up a child. Dr. Winnicott pointed out that complete analysis always included the symptom enuresis. Absence of enuresis itself might be a symptom. The anaesthesia of the sensitive parts of the urinary apparatus was an inhibition of physical sensation secondary to repression accompanying fantasy, disappearing as this became less intense. The most difficult case showed no anxiety or depression, since all emotional difficulties were dealt with by the one symptom, instead of by phobias, obsessional behaviour, moods, and so forth. These remarks did not make treatment easier, but the subject was highly complex, and he sought to understand the forces at work behind enuresis and kindred symptoms in childhood.

Much could be got out of such tricks in treatment as hypnosis, but more from the study of causation. Although this limited the therapy to few cases, it enabled better advice to be given to the mother who wanted to know how best to bring up her child.

Dr. C. J. C. EARL said that the feeble-minded was no more liable to enuresis than was the normal child, although he was usually later in developing toilet habits. Most mentally defective children could be trained. Enuresis was commoner in institutions, in orphanages as well as in mental homes, than outside, and doctors and superintendents would all agree that epidemics occurred, often after the public execution of an offender. One or two children with enuresis could "infect" a ward previously clean. Almost all cases from 10 to 14 years were of excitable type, and he regarded enuresis as a hysterical symptom, seeing that it could be cleared up and produced by suggestion. Drug treatment was as good as any other, but perhaps it was as well that most pædiatricsians gave belladonna in doses too small to have any action. He suggested that the success of any treatment that worked was due to suggestion, the highest common factor of them all. Hypnotism was valuable in high-grade mental defectives.

Dr. FRANKLIN BICKNELL had shown that as little as four ounces of water would swamp a mattress and drip through it. Where spina bifida was a causal factor, relapse was common. In an analysis of his own cases measles and whooping-cough were responsible for a large number with a late onset. There seemed to be two types of child: the flaxen-haired Teutonic type that bullied its mother and failed to clear up, and the small dark "chic" type, having frequent queer attacks of temper, that did well. An abnormally high percentage of cases had orthostatic albuminuria. As regards treatment he discounted the effects of suggestion.

Dr. C. H. ROGERSON objected to the name enuresis, implying a disease. The early English description of the young "piss-abad" suggested more accurately its symptomatic character. He agreed that it cleared up with any one of a number of treatments.

Dr. MARGARET LOWENFELD said that enuresis was merely the persistence of a characteristic normal for the first six months of life. She had been astonished at the number of children who really enjoyed bed-wetting, and said that it was nice. It had to be remembered that a child's scale of enjoyment differed from the adult's. The attitude towards bodily sensations was important. Some portrayed emotions with their bodies, some did not. She agreed that the psychologist's cases were selected from among the former, making special study possible. Boys, who predominated, all had continuous and unusually vivid fantasies. Their preponderance could be explained by the greater dramatic possibilities of the urinary function of boys compared with girls. In the type of child who lacked correlation between mind and body, sleep was so deep that the acquired control was lost.

## EDINBURGH OBSTETRICAL SOCIETY

At a meeting of this society on March 11th, with Dr. DOUGLAS MILLER, the president, in the chair, a paper on

**Radium and Cancer of the Neck of the Uterus** was read by Sir COMYNS BERKELEY (London). He referred to the tragic and often unnecessary delay

in making a diagnosis and instituting efficient treatment. In a group of cases he had investigated he had found that the average time from the initial symptoms till a doctor was consulted was five months, and before proper treatment was established after diagnosis another five months elapsed. The blame therefore lay partly with the patient and partly with the medical profession. As remedies for this state of affairs Sir Comyns stressed first the importance of disseminating knowledge, indicating when menstruation was to be considered normal, and advising vaginal examination if any irregularity developed. This should be done at post-natal clinics by leaflets and verbal instruction, by hanging a notice in gynæcological out-patient departments, and educating midwives to spread the information and persuade women with irregular vaginal bleeding to consult their doctors. Secondly, he said, not only was it the practitioner's duty to examine locally and investigate completely all cases of irregular vaginal hæmorrhage, but all cervical erosions should be treated thoroughly, and if they did not respond quickly, a biopsy was indicated. He fully realised the difficulties practitioners faced, especially when blamed for making an unnecessary fuss where the findings proved negative. Recently the British Empire Cancer Campaign had set up a central propaganda committee, lectures being organised for the lay public to be given by local doctors. This was at present being tried in certain districts.

Sir Comyns's cases showed that in 30 per cent. of cases of cervical carcinoma the patient was between the ages of 50 and 60, and childbearing was an important precursor, 95 per cent. of patients being married, and the average number of pregnancies being 5.4. In treatment a general anæsthetic should always be given because a more detailed examination was possible and efficient application even with a multiplicity of applicators was by no means always easy. Whether or not X rays should supplement radium treatment was still in debate. Heyman of Stockholm was not yet convinced of its benefit but found the radium bomb had a definite place in extreme cases. Theoretically, Sir Comyns felt, it was sound, and it was now being undertaken as a routine at his clinic. Before reliable statistics, which were badly needed, could be published, efficient follow-up systems, which meant much work and ingenuity, must be evolved; and the preliminary examination and grouping of cases, the treatment and the follow-up examinations should only be made by the chief and his first assistant so that the same standards were as far as possible maintained. To place a case in its proper group was often no easy matter, and in a difficult one Sir Comyns advocated "up-grading" as the proper course to follow—i.e., choose the group where there is the greater chance of recovery. A bimanual examination did not always indicate the real amount of spread—for example, to the bladder. On the other hand, parametrial masses suggesting malignant spread often turned out to be inflammatory. "Down-grading" was liable to result in this type of case being placed in too low a grade, and so statistics were falsified by improving both Stage I. and Stage IV. The only survival-rate of use for purposes of comparison between different centres was the absolute survival-rate—i.e., the calculation to be made from all cases seen whether treated or not. It would eliminate the effects of up-grading or down-grading, and was vastly superior to comparisons of the gross or net survival-rate.

## REVIEWS AND NOTICES OF BOOKS

**The Human Foot**

By DUDLEY J. MORTON, Associate Professor of Anatomy, College of Physicians and Surgeons, Columbia University. Columbia: University Press; London: Humphrey Milford, Oxford University Press. 1935. Pp. 244. 15s.

ANYONE who doubts whether a book on the human foot is likely to be wanted by enough readers to justify its publication has reckoned without the peculiar gifts of Dr. Morton. He has written a book on the foot, its evolution, anatomy, mechanics, and physiology, which is so good that it will undoubtedly create a demand. The first part deals lucidly with evolution, and the second with mechanics. Dr. Morton is at pains to emphasise the relation of the mechanics of the foot to the posture of the body as a whole in states of activity and in rest. From anatomical considerations alone it would appear that the foot is divided longitudinally into two parts, each with a different function: an inner part which is essentially the lever and spring, and an outer which is a base of support and a balancing organ for the lever, and takes relatively very little part in leverage action. Dr. Morton carried out, by means of an instrument of his own design called a staticometer, investigations which have a bearing upon this point. He was able to determine the amount of weight borne by each of the metatarsal heads when the foot was in action and at rest, and found that in action the line of stress came between the first and second metatarsal bone and at rest between the second and third. He therefore recognises two axes: an axis of leverage and an axis of balance. This differentiation of function is a useful conception, and gives to the outer part of the foot and even to the little toe a new significance. It helps to explain the mechanical disabilities of feet which fall even within the normal range, such as the relatively high arched and long narrow ones.

In discussing metatarsalgia Dr. Morton devotes a chapter, illustrated by good X ray photographs, to each of the three congenital conditions long associated with the name of Morton: a short first metatarsal bone, a mobile first metatarsal, and a backwardly placed sesamoid bone. He has rendered a service in once more drawing attention to these conditions, since they are probably responsible for far more cases of mechanical breakdown of the foot than is generally realised. Throughout the book he emphasises his points by ingenious diagrams, of which the one illustrating the mechanical ill-effects on the feet of a shortened tendo Achillis is a noteworthy example.

**From Rousseau to Proust**

By HAVELOCK ELLIS. London: Constable and Co., Ltd. 1936. Pp. 411. 12s. 6d.

In this book Dr. Havelock Ellis writes in his usual fluent style of the literature of France. In the opening chapter he tells how, by the age of 14, he had acquired French enough to read for pleasure in that language. The first French book he read for its own sake was Rousseau's "Rêveries." It was not till 1883, many years later, that he first had occasion to visit France. In 1889 he went again with his friend Arthur Symonds. Lightly and reminiscently he sketches the great literary and artistic figures with whom he came thus in contact—Coppée, Meissonier, Mallarmé, Rodin, Verlaine, Huysmans, and

many more. He had the unusual experience of hearing the great Bernhardt hissed at the end of a dull play. The brilliant study of Rousseau which follows includes a chapter on that enigmatic and attractive woman Mme de Warens, whose influence on Rousseau was so profound. Subsequent essays deal with Restif de la Bretonne, "le Rousseau de ruisseau"; Besenval who, though half Polish, was the perfect type of the French chevalier; Alexandre de Tilly, the typical roué of the eighteenth century; Victor Hugo, whose "colossal superiority-complex" was his defence against the world; and, by contrast, Verlaine, who "represents genius, naked and helpless." Next come Élie Reclus, one of those men who are ranked among the criminals while they live, among the saints when they are dead; Remy de Gourmont, critic, scholar, and recluse with the Kantian capacity for visualising conditions of which he had had no personal experience; Henri de Régner, who remained spiritually always a child; and Alain-Fournier, author of "Le Grand Meaulnes." Last comes a profoundly critical study of Marcel Proust, that erratic and contradictory figure who was a victim of nervous asthma. In the author's view Proust's work was largely conditioned and developed by this allergic state. This is not a book for the tyro nor even for the man with a mere nodding acquaintance with French literature, but those whose interest in the great and small men peopling this book is not perfunctory will appreciate the skill with which their characters are portrayed.

**Diseases of the Peripheral Arteries**

*Diagnosis and Treatment.* By SAUL S. SAMUELS, A.M., M.D., Chief of the Clinic for Peripheral Arterial Diseases, Bellevue Hospital, New York. London: Humphrey Milford, Oxford University Press. 1936. Pp. 260. 12s. 6d.

THIS book is concerned almost entirely with thrombo-angitis obliterans and is written to advocate conservative methods of treatment for all forms of obliterative arteritis in the extremities. The author has had very considerable experience as chief of the clinic for peripheral arterial diseases at the Bellevue Hospital, and though he does not give his figures in full he states that in his series of 350 cases of obliterative arteritis treated during the past ten years only *one* required amputation. This astounding result has been achieved not so much by special methods of treatment as by Dr. Samuels' determination to persist with conservative methods when most physicians would resort to some more drastic measures to alleviate the patient's suffering. There are clinical records of case after case in which to save a leg the patient has had to endure what the author describes as excruciating agony for several weeks while gangrenous toes were separating, and has been an invalid for 6 to 12 months before healing was complete. That sound healing may be obtained by conservative treatment after gangrene has appeared is in itself a matter worthy of note, and justifies the publication of this monograph, but it is regrettable that Dr. Samuels has given no indication of the after-history of these cases. Although all agree that everything should be done to avoid amputation, it must be remembered that the disease in the arteries is progressive, and one hesitates to adopt a method of treatment which involves much pain

and prolonged invalidism without some assurance that the healed stumps after loss of the toes are unlikely to break down again when the patient returns to his usual activities. The cardinal rules of treatment are rest with the limb horizontal, hot baths (but avoidance of radiant heat), intravenous salines, and baths and wet dressings of weak chloramine for ulcers and gangrene. The author lays great stress on complete abstinence from tobacco, and states that even moderate cigarette smoking can rob the patient of the benefits derived from the most painstaking practice of all the other methods of treatment. The arguments in support of conservatism are weakened rather than strengthened by the author's repeated refusal to consider any form of surgery to improve the peripheral circulation, and he condemns every kind of operation with unnecessary vehemence. Though lacking in depth of thought and width of outlook the book deserves the consideration of practitioners interested in these vascular diseases, of which the incidence seems to increase as the years go by.

### Plant Viruses

By KENNETH M. SMITH, D.Sc., Ph.D., Potato Virus Research Station, School of Agriculture, University of Cambridge. London: Methuen and Co. 1935. Pp. 107. 3s. 6d.

THOSE who wish to know something about the virus diseases of plants, but have not the time to tackle a large treatise, will find Dr. Kenneth Smith's little monograph the very thing they have been looking for. Despite its brevity it contains a clear and comprehensive outline of what is known about plant viruses. The book begins with a brief historical survey and a statement of the problem as envisaged to-day by plant pathologists, stress being laid on the great economic importance of these diseases. Following this is a chapter on the technical side of the question and here one gets a glimpse of some of the obstacles that the investigator of plant viruses has to cope with. The main portion of the book is devoted to a consideration of the behaviour of the virus in different environments, in the host, in the insect vector, in vitro, and of the way in which these virus diseases are spread. A chapter on immunity follows and the book closes with a brief comparison of animal and plant viruses. Considering the difficulties inherent in plant virus research it is extraordinary how much progress has been made in unravelling knots which seemed to be firmly entangled only a few years ago. In this work Dr. Kenneth Smith has taken a prominent part and his monograph may be regarded as authoritative.

### Behaviour Development in Infants

*A Survey of the Literature on Prenatal and Post-natal Activity, 1920-1934.* By EVELYN DEWEY. Published for the Josiah Macy, Jr., Foundation by Columbia University Press. London: Humphrey Milford, Oxford University Press. 1935. Pp. 321. 17s. 6d.

ALTHOUGH this volume comes into the class of "books about books," it is much more than a summary of other publications. The author has sifted a prodigiously large number of original works, and has presented a lucid and coherent account of the theories and observations of normal child development published since 1920, when the scientific and intensive study of the subject began to be pursued

on a large scale. An outline of the Behaviourist and Gestalt theories of child development is followed by an account of the various views of correlation of structure and function deduced from animal studies. The book is subsequently divided into sections dealing with the behaviour of the human foetus, neonatal behaviour, and behaviour during infancy. Although the obvious difficulties besetting the study of the behaviour of the human or any other foetus will probably make many of the theories here recorded appear grotesque in the light of subsequent knowledge, it will astonish most readers to find how much is actually known about the foetus as a sentient being, and on what clear evidence post-natal behaviour must be regarded as the direct continuation of intra-uterine behaviour. This book should prove of worth not only to those working on any branch of the subject, but also to the more general reader. The Josiah Macy, Jr., Foundation, to whose suggestion and support the investigation is due, deserves congratulation for having initiated a valuable piece of research, and for having chosen the right person to pursue it successfully.

### Infra-red Irradiation

By WILLIAM BEAUMONT, Honorary Physician and Medical Director, Institute of Ray Therapy; Lecturer in Electrotherapy, the Swedish Institute. With a foreword by Lord HORDER, K.C.V.O. London: H. K. Lewis and Co., Ltd. 1936. Pp. 139. 6s. 6d.

In this small volume Dr. Beaumont gives a lucid and concise presentation of infra-red therapy, suitable for consultation both by the practitioner who wishes to acquaint himself with principles and by the nurse who carries out the treatment. Apparatus is briefly described and indications are given for routine technique. The analysis of over one thousand cases treated by the author shows that relief of pain can be expected in a considerable number of cases of rheumatoid and osteo-arthritis, fibrositis, neuritis, and neuralgia. In a smaller number some permanent improvement is recorded. The subject is approached mainly from the clinical side. The manual makes no claim to be a scientific treatise, and indeed it adds little to our scanty knowledge of the mode of action of infra-red radiations in the relief of symptoms and to the relative value of any given region of the infra-red spectrum. But it has value as a practical guide to treatment and as a record of the results obtained by an experienced and fair-minded observer.

### Psychology and Practical Life

By MARY COLLINS, M.A., B.Ed., Ph.D., Lecturer in Psychology, University of Edinburgh; and JAMES DREVER, M.A., B.Sc., D.Phil., Professor of Psychology at the University. London: University of London Press. 1936. Pp. 307. 5s.

THIS is an elementary text-book which can also be read with interest and profit. Broadly speaking it is devoted to industrial and vocational psychology, but its introductory chapters give clear expositions of fundamental psychological processes and child development, without an understanding of which the untrained reader would not follow the application of psychology to industry and education. Those who are being educated and who ultimately find a place in the community have different capacities

of learning, and different temperaments; the authors have therefore included chapters on tests for emotion, temperament, and volition, as well as on acquisition of skill and methods of learning. Thus the ground is adequately prepared for chapters on vocational psychology, psychology of work, and advertising. Mental deficiency and crime are properly dealt with as social problems; but it is unfortunate that psychology and health have been disposed of in only twenty pages. Psychopathology and child guidance have made it clear to us that the dynamic of character formation influences life at all points; that the child's capacity to learn can be emotionally determined; that monotony can be due to individual peculiarities; and that accidents can be deliberate; and that advertisers must think of vanity, fear, prestige, and sex appeal. Surely this aspect of practical psychology deserved, even in an elementary book, some deeper and wider consideration. This omission, however noticeable to experts, does not detract to any extent from the value of the book, which is clear, informative, and fair in expression of opinion on problems not yet settled.

### British Journal of Surgery

THE April issue (Vol. XXIII., No. 92) contains the following articles:—

Radiography of the Duodenal Cap, by G. R. MATHER CORDINER and G. T. CALTHROP (London). Attention is drawn to the limitations of deformity of the duodenal cap as evidence of ulceration. A description is given of the Berg technique of aimed exposure. The variations in the mucosal folds, the ulcer niche, and fixation by adhesions and by penetration of the ulcer base are described and illustrated.

Encrustation of the Bladder as a Result of Alkaline Cystitis, by H. G. LETCHER and N. M. MATHESON (London). In the case described encrustation involved almost the whole of the mucosal surface, and was visible in a radiogram. Repeated lavage with weak acetic acid solution caused rapid disappearance of the deposit and healing of the underlying ulceration.

Spontaneous Rupture of the Extensor Pollicis Longus Tendon Associated with Colles's Fracture, by THOMAS MOORE (Newcastle). In the three cases described the fracture had been treated by the unpadded plaster cast. Early use of the thumb in the presence of a damaged tendon is suggested as a possible cause.

Solitary Plasmocytoma of Long Bones, by JUDSON T. CHESTERMAN (Sheffield). The features of the case recorded were history of injury, localised pain, and pathological fracture. The relation of this tumour to other types of myeloma is discussed, together with its prognosis. Treatment by curettage and bone-graft are advised.

The Bladder Function in Spinal Injury, by KENNETH H. WATKINS (Manchester). The conclusions reached from observation and repeated tests on eight patients are that in complete transverse lesions reflex involuntary micturition is established, while in lesions of the conus and cauda equina micturition involves voluntary strain, the function of the detrusor muscle being seriously impaired.

A Case of Spinal Tumour, by T. SATAKOPAN and N. MANGESH RAO (Madras). The tumour, a cellular fibroma, lay in the arachnoid unattached to the dura and caused spastic paresis of the legs. It was successfully removed.

A Carcinoid Tumour of the Lower Ileum, by W. QUARRY WOOD (Edinburgh). Successful radical operation was performed. The potential malignancy of these tumours is discussed, and their origin traced to the Kultschinsky cells of the mucosa.

Colloid Tumour of the Urachus Invading the Bladder, by R. CAMPBELL BEGS (Wellington, N.Z.). The patient suffered from recurrent attacks of hæmaturia and fre-

quency. Free excision was performed. The growth was found to be papilliferous with tall columnar epithelium.

Two Cases Illustrating the Latency of Large Renal Calculi and their Relation to Pregnancy, by JAMES COOK (Birkenhead). In one case a large branched stone was discovered owing to an attack of perinephritis during the puerperium; in the other, bilateral calculi threatened anuria in the early weeks of pregnancy.

Three Cases of Duodenal Diverticuli Removed by Operation, by H. N. FLETCHER and L. I. M. CASTLEDEN (Brighton). Pain, gastric flatulence, and vomiting were the most conspicuous symptoms. The justification for operation is discussed. No particular technical difficulty in removal was encountered and the results justified the treatment adopted.

Fracture of the Neck of the Femur, by R. WATSON JONES (Liverpool). A description of the technique and results of a modification of the Smith-Petersen operation. The author exposes the fracture site by a lateral incision and uses a heavier guide than usual over which the hollow nail is threaded and introduced by sight. He obtained bony union in 32 per cent. of the last 35 cases treated.

Two Cases of Cystadenoma of the Pancreas, by ROBERT M. JANES (Toronto). Operation in the first case presented great difficulty and removal was incomplete. A recurrent cyst was subsequently marsupialised.

Prostatectomy with Closure: Addenda and Some Observations, by S. HARRY HARRIS (Sydney). A new sucker-retractor is described. Some misconceptions as to technique are corrected and attention is drawn to the later method of trigonisation.

Intestinal Strangulation, by G. C. KNIGHT and DAVID SLOME, from the Research Department, Royal College of Surgeons of England. An account of experiments which go to prove that the important lethal factor is the production in the tissues of the gut of a toxic substance, which is absorbed into the circulation. Fluid loss was shown to be of very secondary significance.

Papers on rare and interesting cases are also included.

## NEW INVENTIONS

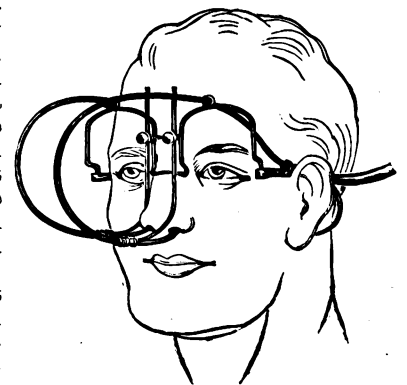

### A NASAL CATHETER HOLDER

THE nasal catheter is commonly employed for oxygen administration as it is often the most practicable method. The catheter is usually attached to the patient's face by adhesive tape. This method of fixation is insecure and may irritate the skin. Another method is to employ a band round the head. Such an appliance is not easily sterilisable and is not well tolerated; in patients who perspire freely it has been known to set up dermatitis of the forehead.

To obviate these disadvantages a modified spectacle frame was devised, the important features of which are: (1) it is light, durable, and does not grip the head; (2) the flexible wire supports are adjustable and ensure that the catheter is directed horizontally backwards and not upwards; (3) it can be readily sterilised.

The makers are Messrs. A. L. Hawkins and Co., Ltd., 66, New Cavendish-street, W.1.

# THE LANCET

LONDON: SATURDAY, MAY 2, 1936

## OVERCROWDING OF HOSPITALS IN LONDON

A CERTAIN amount of prominence has recently been given to overcrowding in the hospitals of the London County Council and especially to the shortage of beds for the chronic sick. In taking over institutions of a great variety in type from a number of independent poor-law authorities, the L.C.C. was faced in 1930 with a complex problem. In addition to 31 hospitals proper, 12 of the 26 mixed institutions were handed over forthwith to the management of the central public health committee, as a provisional arrangement. In October, 1934, however, a new scheme of classification of patients was adopted and a reconstitution of institutions carried out to overcome the administrative confusion of having 4700 public assistance cases under the management of the hospitals and medical services committee and 1600 of their cases in public assistance institutions. It was recognised<sup>1</sup> that the reshuffle would be a difficult and necessarily gradual process, and entail substantial and costly improvements in some of the existing buildings. Until the final effect of these changes become demonstrable it seems wise on the part of the L.C.C. to have deferred its programme for new hospital provision. As Prof. R. M. F. PICKEN pointed out in a recent discussion at a sessional meeting of the Royal Sanitary Institute at Swansea, many questions in relation to hospitals have to be taken into consideration, such as the future numbers and location of the population, the most suitable size of hospitals, the advantages and disadvantages of specialisation, the prospect of extension of voluntary hospitals, and the readiness of the managers of the latter to pool their beds with the rate-aided. The voluntary hospitals, he said, should recognise that the staffs of council hospitals—which are training schools for nurses and may even be attached to medical schools—will not readily agree to the relegation to them of nothing but the chronic, hopeless, and uninteresting types of disease. On the other hand the council hospitals might, he thought, devote special attention to disabling but not emergency conditions which affect so many patients on voluntary hospital waiting-lists—the hernias, hydroceles, varicoceles, hæmorrhoids, and gynæcological troubles. This would be truly in line with the

preventive traditions of local authorities, since it would reduce disability and prolong the productive period of life.

In the meantime, the net effect of the L.C.C.'s efforts appears to have been a reduction in the nominal number of beds available for the sick, while the demand for admission has increased. In 1931 the number of poor-law institutions in London affording accommodation for the sick was 25, with 8890 sick beds, but these figures had fallen to 21 and 6882 in 1934<sup>2</sup>; general hospitals, so-called (they include children's hospitals, convalescent homes, and institutions for epileptics and venereal diseases), had increased from 35 to 40, and the contained beds from 20,141 to 21,210. Altogether, therefore, there has been a loss of nearly 1000 beds which, whether appropriately or not, had been at one time regarded as accommodation for the sick. In the same period the total number of admissions rose from 179,024 to 188,513, an increase of more than 9000 patients. It may justifiably be assumed that, if overcrowding has arisen during this period of adjustment, the patients are otherwise receiving far better medical and nursing care than those who were formerly admitted to the more ample accommodation which was ostensibly reserved for the sick. In the long view there is a strong case for hurrying slowly in this matter of hospital provision. Apart from questions as to the suitability of many former poor-law hospitals and institutions and the imperfect coördination so far established with the voluntary system, the whole complexion of the problem may change rapidly. In London some 1200 to 1300 beds may be occupied at any one time by cases of diphtheria and about 2000 by scarlet fever. If London can follow the American example and institute such a successful scheme of immunisation as Dr. GRAHAM FORBES has worked for over so many years; and if the public can be converted to a less intensive hospitalisation of scarlet fever, so long as it retains its present mild form, accommodation might become available which would be adequate for many forms of acute medical disease now admitted to general hospitals. The population, too, is ageing, a fact which may involve a proportionate increase of chronic illness, with a corresponding change in the type of provision needed. Moreover, as the last two censuses have shown, there is an outward drift of population from the area which the L.C.C. administers, thus creating new and very acute hospital problems for the home counties. If it continues London's difficulties may become less acute.

## AN EIGHTIETH BIRTHDAY

ON the sixth of May eighty years ago, at Freiberg in what is now Czechoslovakia, SIGMUND FREUD was born, the son of Jewish parents. Over forty years ago he began in Vienna the publication of observations and theories that have made his name known throughout the world and will, in the estimation of many people, give it a place in

<sup>1</sup> THE LANCET, 1934, ii., 1187.

<sup>2</sup> Sixteenth Annual Report of the Ministry of Health, 1934-35, p. 98.

the history of the development of human knowledge. FREUD describes in his autobiography<sup>1</sup> how interest led him to the study of organic diseases of the nervous system and how he came to realise the failure of therapeutics when faced

with the crowds of neurotic patients who, as he says, hurried, with their troubles unsolved, from one physician to another. It was with the aim of studying these conditions that he visited CHARCOT in 1886, and it is noteworthy that his accounts of hysteria in men and of the production of hysterical paralyses by suggestion were derided on his return to Vienna.

Further visits to BERNHEIM and LIÉBAULT at Nancy were followed by the development of the method of abreaction of hidden memories under hypnosis as a means of treatment, and the publication, with BREUER, of "Studien über Hysterie" in 1895. This was the end of the pre-analytic era, for FREUD, still dissatisfied with his results, patiently worked out the technique of free association which still remains the essential weapon of psycho-analysis. The existence of an unconscious part of the mind, which had for ages been a speculation of poets and philosophers, now emerged as the key not only to psychoneurotic symptoms but to a great part of human activity. Moreover, its contents were no longer a matter of speculation but of investigation.

Psycho-analysis has now found recognition in all spheres of life where human thought and behaviour are in question, and has so far permeated medicine that even those who still count themselves its opponents have often accepted many of its teachings whilst apparently remaining ignorant of their origin. A curious charge against it at one time was that it dethroned reason, whereas, by its recognition of unconscious emotional forces, it strengthens enormously the function of reason as a guide. In this quality we may see the cause, besides anti-semitism, of its suppression in the totalitarian States of Europe, where publication of books on psycho-analysis is prohibited. The opposition that met psycho-analysis nevertheless calls for examination. FREUD's teachings involved a fundamental change of outlook, for they concern unconscious motives of behaviour, the recognition of which runs counter to our philosophy and our pride, and to this rather than his insistence upon

the importance of sex must be attributed the opposition encountered. This opposition, and the isolation that was forced upon him for years, undoubtedly influenced FREUD's attitude to the scientific world. He made no concessions and never attempted to bring his findings into relation with the general body of psychological theory. Confirmation has come chiefly from the medical side and there is now an attitude very different from that which once found expression in uncompromising hostility. Yet discussion has played little part in this change. FREUD rarely made a direct answer to his critics, nor have his followers in this country often troubled to defend their beliefs. Useful criticism has, indeed, been lacking, for knowledge of the observations upon which the theory is based can only be obtained by making those observations oneself, and most criticism has consisted of a denial of the observations. Hence psycho-analytical doctrine has grown up without that healthy criticism which is both a stimulus and a check to scientific theory. Yet FREUD has always shown himself capable of revising, correcting, or even casting aside his own views, and his writings, when not admittedly speculative, are marked by a realisation of the difficulty the man of ordinary training and beliefs has in understanding views that concern a sphere hitherto separated from his conscious experience.

FREUD has been acclaimed as another DARWIN, and there are resemblances between the opposition he has met and that met by the pioneer of modern theories of evolution. He certainly had as hard a road to travel. DARWIN wounded man's anthropocentric pride; FREUD struck deeper and shook his egocentric beliefs. We are now recovering from the shock and realise that we have lived through another of those controversies that, as much as the discoveries arousing them, form landmarks in the history of science.

## THE NEW GRADES OF MILK

THE grading of milk was introduced in this country in 1923. Its object was to reward producers who took the trouble to abide by certain rules and attain certain standards: they were given a right to call their milk by certain statutory names, which would, it was hoped, give them a commercial return for their pains. Alas, the public was slow to respond, and its apathy was strengthened by inability to understand what the various designations really signified. The passage of 13 years has not completely removed the difficulty of distinguishing between the status of Certified, Grade A (tuberculin-tested), Grade A, pasteurised, and Grade A (pasteurised) milk, and it has long been evident that the original regulations considered the producer too much and the consumer too little. The same may be said of the new Order, issued last Saturday and due to come into force on June 1st, which is summarised on p. 1036.

Whenever of late years the Ministry of Health or the Board of Agriculture has been pressed to deal with the scandal of the existing milk-supply

<sup>1</sup> An Autobiographical Study. By Sigmund Freud, M.D., LL.D. Authorised translation by James Strachey. London: Hogarth Press, 1935. 6s. The photograph here reproduced is taken from the *Galerie hervorragender Aerzte und Naturforscher*, issued in supplement to the *Münchener medizinische Wochenschrift* (1930).

the reply has been that the Government had set up a special committee of inquiry, and that action must wait on its report. This body, the Committee on Cattle Diseases, with Sir GOWLAND HOPKINS as its chairman, sat for nearly two years and studied the milk problem as it has never been studied before. Their conclusions, published in May, 1934, included definite proposals for regulating the whole milk-supply on scientific lines. They recommended, along with important measures for the control of bovine tuberculosis, that *all* milk for consumption in liquid form should be sold under official designation—either as certified milk, pasteurised milk, sterilised milk, or milk (uncertified). Even the last group, which was milk neither pasteurised nor from tuberculin-tested cows, had to reach a certain hygienic standard, and it is noteworthy that it was to be given a name that indicated its unreliable nature. After two years, during which no Government department has acted on these proposals, we have the new Milk Designations Order; and presumably it is all we shall get for a long time to come. This Order, it should be understood, has a very small scope and objective. Not only does it preserve the system by which the main bulk of the milk-supply escapes grading altogether—because the production of designated milk is purely voluntary—but it continues to give official blessing under the new name of “accredited” to the present “Grade A” milk. The accredited producers roll is a scheme by which the Minister of Agriculture is very properly trying to raise the general standard, and “accredited milk,” since it comes only from farms where his higher standard is enforced, should be preferable to the undesignated milk which now constitutes the bulk of the market. Nevertheless it does not deserve confidence. The quarterly veterinary examination of the cows, on which so much depends, is less of a safeguard than it may seem, for it notoriously fails to detect tuberculosis and is of limited value in preventing infection of the milk-supply with the tubercle bacillus. Since, in short, accredited milk is no better controlled than Grade A, it is essentially untrustworthy, and its distribution under a special name can only lead the consumer to a false sense of security. The present Order is in this respect worse than the original draft issued last summer: in suggesting the word “standard” in place of “Grade A,” this made the important reservation that the term was not to serve as a label on milk as sold to the public, and was only to be used in the internal administration of the accredited milk scheme. Is it even now too late to revert to this unobjectionable procedure and avoid the retrogressive step of including “accredited” as a designation approved by the Ministry of Health? The medical profession will remain dissatisfied—and rightly—until arrangements are made to secure a clean and safe milk-supply for the whole community. But failing that, it seems inappropriate that the Health Ministry should give countenance to a type of produce which must often be dangerous.

Under the new Order, or any other for a long time to come, the public will find its safety chiefly in efficient pasteurisation. That pasteurising is often inefficient is only too clear, and it is a minor but still serious ground for criticism of the new regulations that they put the inspection and supervision of pasteurisation in the hands of the local sanitary authorities who grant the licences. As we have urged before, this is highly technical work, and comparatively few of the officers of the smaller local authorities possess the knowledge required for it, whereas it could suitably and profitably be undertaken by fully trained officers of county councils and county boroughs. “The Minister is,” we are told, “pleased to learn that a test for pasteurised milk (the phosphatase test) has recently been devised”; and those who have followed the work of its authors, Prof. H. D. KAY and Mr. F. K. NEAVE<sup>1</sup> will share his satisfaction in a most promising piece of work. But for the present we should only accept it as an adjuvant to skilful and experienced inspection.

#### REHABILITATION AFTER INJURY

An Inter-departmental Committee has been appointed by the Home Secretary, the Minister of Health, and the Secretary of State for Scotland to inquire into the arrangements in this country for restoration of the working capacity of persons injured by accidents, and to report what improvements are desirable. The decision to appoint this committee has been taken after consideration of the report issued by the British Medical Association last year, in which suggestions were made for improving the organisation of fracture treatment, and in which attention was drawn to its industrial importance. The chairman is Sir Malcolm Delevingne, formerly deputy permanent under-secretary at the Home Office, and the medical members are Dr. Muriel Bywaters, Mr. W. A. Cochrane, Dr. Thomas Ferguson, Prof. E. W. Hey Groves, Mr. H. S. Souttar, and Mr. A. C. T. Woodward.

It is announced that the General Education Board, founded by Mr. John D. Rockefeller, has given three million dollars to the Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, to enable it to build a new hospital adjoining the Rockefeller Institute. There will be 200 beds.

THE award of the gold medal of the British Medical Association to Dr. H. Guy Dain will give general satisfaction. Dr. Dain has just retired from the chairmanship of the Insurance Acts Committee which, as everyone should know, and does not, is the executive of the annual panel conference. Both in the conference and the committee he has done much to obtain for medical men employed under the Insurance Acts the conditions they need to make their work satisfying and efficient. Coming as he does from a city where the standard of public service is conspicuously high, he has given skill and devotion to the causes he has at heart; and he has won friendly respect on all sides.

## ANNOTATIONS

## SPECIFIC CONTROL OF MEASLES

IN a recent address to the Hunterian Society on the control of measles Dr. J. A. H. Brincker emphasised<sup>1</sup> the fact that the older methods have failed and expressed the opinion that with the adoption of passive immunisation by means of human immune serum or placental extract we have entered on a promising stage of the battle against the disease. It has been the practice of the county medical officer to issue reports upon successive measles epidemics in London, and the most recent of the series which deals with the 1933-34 epidemic has just been published.<sup>2</sup> As in its predecessors, special attention has been paid to the results of the use of immune measles sera in the control of outbreaks of the disease in L.C.C. hospitals, institutions, and residential schools, and Dr. Wm. Gunn, in conjunction with Mr. W. T. Russell, F.S.S., is again responsible for a statistical study. As our readers are aware, the pooled serum, suitably collected, tested, and prepared, of convalescent measles patients or of adults (preferably young adults who have had an attack of measles not more than ten years previously) may be used either temporarily to prevent or to attenuate, with resultant active immunity, the expected attack of the disease in exposed susceptible children. For obvious reasons convalescent serum is difficult to obtain, but the collection of adult serum in considerable quantity presents no insuperable obstacles if collection is organised. It is the general experience, however, that since the protective value of individual samples of adult serum is lower than that of recent convalescent serum, and that wider variations in value occur, it has to be injected in larger doses and that some batches—due in part, perhaps, to the average attack-bleeding interval being too long—are of relatively low value.

Gunn and Russell base their present statistical study on data derived from 1874 individuals inoculated with either convalescent or adult serum. To confer complete protection a minimum dose of 5 c.cm. of convalescent serum or 10 c.cm. of adult serum was injected into children under 3 years of age within six days of exposure. For attenuation these doses were employed on or after the sixth day; or, alternatively, half these standard doses earlier than the sixth day after exposure. The doses of serum given to older children were graduated according to age. Among the conclusions reached from an analysis of the data is that adult serum prevented the attack in 78.2 per cent. of the instances in which this was desired—compared with 77.9 per cent. in the 1931-32 epidemic. Since in that epidemic experience was held to show that, under institutional conditions, 25 per cent. of exposed children escape attack whether injected or not, the conclusion is reached that injection secures that three times as many children escape attack as would have escaped if no serum had been given. For some reason convalescent serum produced results inferior to those obtained in the preceding epidemic: attenuation 80 per cent. as compared with 87.8 per cent.; prevention 38.5 per cent. against 40.2 per cent. Further, the superiority of convalescent serum over adult serum is not confirmed by the present study—a surprising finding for which, it is said, no ready explanation has been forthcoming. These observers emphasise that, for attenuation,

one-half the standard dose within six days of exposure is preferable to the full dose at a later period. They consider that a flat dose of 10 c.cm. of adult serum is as effective as an age-adjusted dose and that whereas this dose is perhaps too large for attenuation it is more effective for prevention than one of 5 c.cm. It is stated that the protection rates were significantly higher during March to May than in the previous quarter, and at any time were highest among children suffering from diphtheria and lowest among those suffering from scarlet fever and whooping-cough. To account for the high protection rate among diphtheria patients it may be surmised that other factors were operative, such as specially prompt removal of the infecting child.

Direct comparison of the clinical attacks of measles among the inoculated and the controls showed a significant advantage to the former in respect of initial manifestations, severity of main features, complications, and fatality-rates. The apparent equality of adult and convalescent serum must be regarded, even for attenuation, as a singular finding; a partial explanation may be found in the short attack-bleeding interval, the donors being chiefly young women, since, although the number of observations was too small for a decisive test, adult serum with an interval under ten years returned a protection rate of 100 per cent. Experience hitherto has been that although for attenuation there may be little to choose, for prevention convalescent serum is the more reliable. However this may be, it appears probable, as Dr. A. Joe pointed out in our last issue (p. 972), that in placental extract we are likely to be provided with a "reagent . . . less potent perhaps than convalescent serum, but at least equal to adult serum" and, as he says, in view of the difficulty of maintaining an adequate supply of either, its importance can hardly be over-estimated. Although Dr. Joe appears to have had little trouble with reactions following the injection of the products he employed, this is not the universal experience.<sup>3</sup> The earlier American preparations were by no means free from this defect which was believed to be due in part to the presence of tissue proteins. When it has been demonstrated upon a large scale that placental extract is at least as potent as adult serum—which, after all, might reasonably be expected to be the case—and that its injection causes nothing beyond trivial reactions, the control of measles, if the public permits, is in sight. The provision of a supply clearly presents no difficulties. That does not, of course, mean that measles can be prevented.

## FOREIGN BODIES IN THE OESOPHAGUS

FOREIGN bodies stuck in the oesophagus are rightly recognised by patients as surgical emergencies. Unfortunately some of the common oesophageal foreign bodies, such as chicken and fish bones, buttons and boluses of food are relatively non-opaque to X rays. Wendell G. Scott and Sherwood Moore<sup>4</sup> have evolved a routine technique for demonstrating such non-opaque bodies. The method is, briefly, as follows. Antero-posterior and lateral "scout" films of the neck are first taken. If these are negative, the patient is observed by the fluoroscope whilst swallowing a thick barium mixture and any abnormality is noted. Thirdly, antero-posterior and

<sup>1</sup> THE LANCET, Jan. 11th, p. 103.  
<sup>2</sup> London: P. S. King. No. 3180. 1s.

<sup>3</sup> THE LANCET, 1935, ii., 728.  
<sup>4</sup> Jour. Amer. Med. Assoc., March 14th, 1936, p. 906.

oblique radiograms are taken while the patient is rapidly swallowing a thin solution of barium sulphate. The presence of a constant filling defect and a persistent mass of barium in the lumen is regarded as sufficient evidence on which to diagnose a non-opaque foreign body. Rapid exposures and technically perfect films are necessary. The authors consider that œsophagoscopy should be done as soon as the X ray diagnosis is made, since foreign bodies are apt to shift. Even though radiographic evidence is negative, they think œsophagoscopy is warranted if the patient's symptoms point to foreign body, and that the public should be warned against attempting to shift sharp foreign bodies by swallowing large boluses of food, a procedure which may cause perforation of the œsophagus. Films and fluoroscopic studies should include the nasopharynx and stomach.

## THE DEVELOPMENT OF A GENERAL HOSPITAL

SOME 15 years ago Dr. C. J. Macalister wrote a short history of the Royal Southern Hospital, Liverpool, in connexion with the jubilee commemoration fund of new buildings. This work is now out of print and the purpose of a new edition is to provide a more inclusive record of the hospital and of those who have worked for it.<sup>1</sup> The result is an interesting history of a first-class institution and a pertinent commentary on the development of medicine and surgery through all but a hundred years, for the jubilee commemoration, alluded to above, had reference to the existing buildings which were opened in 1872 and not to the original foundation of the hospital whose inception dates from 1838. Consequently Dr. Macalister had vast developments in medical treatment to tell of as implied by the foundation of all the special departments in the Royal Southern, which to-day find their natural centre in a large general hospital. Among these accounts of special work none is more interesting than the rise of the Liverpool School of Tropical Medicine which is described with a detail justified by its seniority, for the Liverpool School of Tropical Medicine preceded the London School in the commencement of its activities by several months. Both schools had their origin in the decision by Joseph Chamberlain, in 1898, to advocate that medical officers selected for appointments in the tropics should have previous and special knowledge of the diseases with which they might have to deal, an opinion to which immediate effect was given by the General Medical Council in recommendations which were reflected in the medical curriculum. The foundation of the Liverpool school will always be associated with the name of William Carter, who had previously called attention to the large number of cases of tropical diseases which from the early days of the Royal Southern had been brought to the wards. Dr. Carter secured the immediate support of Sir Alfred Jones, the well-known shipowner, for the establishment of a tropical school, and in 1899 a laboratory in connexion with the new department was opened by Lord Lister, when the wards allocated for the tropical cases held occupants who represented many nationalities and had contracted their diseases in all parts of the world. The foundation of the fifteen other special departments is noted, and the clinicians associated are enumerated with an appropriate estimate of their work. A picture of successful administration

of a great charity is formed out of chapters upon the clinical teaching, the nursing and almoner's services, and an able study of the social welfare of patients belonging to different types and grades.

A second section of the book sets out brief biographies in order of appointment of past members of the medical and surgical staffs. Among these biographies we find the names of William Carter, Robert Jones, Mr. G. P. Newbolt, Dr. William Alexander, Ronald Ross, the first lecturer in the tropical school, Noel Chavasse, athlete and military hero, and, to end at the beginning, J. L. Minshull, the accredited originator of the hospital who started the school for the blind in Liverpool and remained consulting surgeon to the Royal Southern Hospital until he died at the age of 82.

Dr. Macalister is to be congratulated on a sound contribution to a chapter in medical history where he himself played a prominent part, having been for many years physician to the hospital, member of the board of management, and chairman of the nursing committee.

## PROPHYLAXIS OF WHOOPING-COUGH

It is doubtful whether vaccines have any value in the treatment of whooping-cough, but evidence in favour of their preventive use is steadily accumulating. Dr. A. D. Gardner, in a lucid account of the prophylaxis, treatment, and bacteriology of pertussis, given before the epidemiological section of the Royal Society of Medicine on April 24th, critically reviewed our present knowledge of the subject, to which he himself has made substantial contributions. The use of a vaccine made from *Hæmophilus pertussis* (bacillus of Bordet) usually implies acceptance of the view that it is the sole ætiological agent. Dr. Gardner considers this established by the constant presence of the organism in the early stages of the disease, its absence from healthy persons and those suffering from other illnesses, and its ability to produce experimentally a spasmodic cough in apes and man. An increasing number of workers are accepting this view.

In the preparation of vaccines, it is important to select cultures in the right phase, and those prepared from rough colonies of *H. pertussis* are useless. If, however, the organism is grown on human blood medium, and fresh colonies in the smooth phase are selected, a vaccine is produced whose antigenic power is demonstrable. The more objective evidence of the efficacy of such a vaccine is its ability to stimulate the production of complement-fixing antibodies, which are known to appear in the blood when immunity is acquired by infection, overt or latent. Unfortunately we have no simple test of immunity for clinical use, and it is impossible to determine whether inoculations have conferred protection against the disease. The cutaneous test is unsatisfactory: some claim it to be an immunity index comparable with the Schick and Dick tests; others regard it as a test of hypersensitiveness analogous to the tuberculin tests. The latter seems the more probable explanation. The difficulties of interpreting tests of hypersensitiveness in tuberculosis in terms of immunity need no emphasis, and it is probable that similar difficulties will be encountered with the cutaneous test in whooping-cough. There remains the evidence obtained from a comparison of the frequency and severity of attacks in the inoculated and uninoculated. The difficulty of obtaining properly controlled results in such circumstances is familiar to every worker in the field of artificial immunisation who knows

<sup>1</sup> The Origin and History of the Liverpool Royal Southern Hospital. By Charles J. Macalister, M.D. Edin., F.R.C.P.Lond., Honorary Consulting Physician to the Hospital. Liverpool: W. B. Jones and Co., Ltd. 1936. Pp. 214.

something of the mode of transmission of infectious diseases and the laws of chance. Nevertheless, very suggestive, and sometimes remarkably successful, results have been recorded which justify the prophecy that large-scale protection against whooping-cough is in sight. Even if complete protection is not obtained, attenuation of the disease should be possible; and robbed of its serious complications by attenuation, whooping-cough, like attenuated measles, will cease to exact its present heavy toll of child life.

If active immunisation by vaccines is not yet beyond question, passive immunisation by convalescent or adult immune sera is still less firmly established; but here again there is reason to hope for better success.

### THE TAKING OF SNUFF

THREE hundred pounds of snuff were issued to the 14 mental hospitals of the London County Council in 1934, as compared with 425 lb. issued to 11 hospitals in 1911. This information was given by Sir Robert Armstrong-Jones to Dr. J. D. Rolleston and handed on by him to the Society for the Study of Inebriety and Drug Addiction, when it met on April 21st. But outside mental hospitals the demand for snuff has, it seems, increased threefold during the last five years as the result of a statement in the *Times* by Sir Buckston Browne that the risk of a cold in the head was greatly reduced by taking snuff, its effect being attributed to a stimulation of the nasal mucous membrane, relief of congestion, and a free flow of mucus which washed away the peccant matter. The history of snuff-taking, Dr. Rolleston said, had received more attention from the antiquarian than from the physician. On its first introduction into Europe, in the middle of the sixteenth century, by Jean Nicot, the French ambassador at Lisbon, snuff was used as a medicine, being employed especially in the treatment of migraine, headaches, and colds in the head. It soon however became a luxury, and snuff was taken generally throughout Spain, Italy, and France during the early part of the seventeenth century. In Italy and Spain the clergy became so addicted to it, even during mass, that a papal bull forbidding snuff-taking in churches was issued by Urban VIII. in 1642 and again by Innocent X. in 1650. Snuff was introduced into England at the Restoration by the courtiers and officers who had attended Charles II. in France, and its popularity increased after the Great Plague. Henceforward, until about the middle of the eighteenth century, the snuff-box played an important rôle in the social life of the time; medical works and belles lettres were equally extravagant in praise and denunciation of the new habit. As late as 1870 Dr. J. C. Murray of Newcastle-on-Tyne was recommending its use for the relief of bronchitis and consumption; he stated his belief, in common with others at that period, that snuff was instrumental in preventing scarlet fever, measles, small-pox, pertussis, dysentery, cholera, diphtheria, rheumatism, erysipelas, influenza, and malaria. Other authorities, such as Sir Benjamin Ward Richardson, ascribed to its use various ill-effects, including impairment of the sense of smell, dyspepsia, nausea, loss of strength and appetite, formation of polypi, lead poisoning, and tremor of the hands. After the middle of the nineteenth century smoking rapidly replaced snuff-taking. Up to 1830 the sale of tobacco and cigars was insignificant compared with that of snuff; in 1850 they began to lead. The sanitary commission of 1853 found that snuff was often adulterated with things injurious to health, such as oxide of iron,

chromate and oxide of lead, bichromate of potash, along with considerable quantities of silica and orris root. If snuff was taken pure its effects were, in the commission's view, mainly local. In recent years there has been little or no medical pronouncement on snuff-taking. The chief morbid change due to the habit appears to be a rhinitis, described in 1913 by O. Seifert, which consists in a chronic hyperplasia of the inferior turbinate on one or both sides. Dr. Rolleston said he had been unable to discover how far snuff-taking might become an addiction. An inquiry might be made in printing houses where the habit seems to be fairly general.

### HEARING AIDS FOR THE TEACHING OF DEAF CHILDREN

OF recent years a close study of the factors that influence the audibility of spoken words has led to much improvement in the education of the deaf child. In the April issue of the *Journal of Laryngology and Otology* I. R. and A. W. G. Ewing describe the work done in the department of education of the deaf in the University of Manchester, and those concerned with the problem should not fail to read their paper in the original. It is found, they say, that even a moderately loud conversational type of utterance tends to fall short of complete intelligibility in the technical sense; some of the consonants, especially TH, F, V, and Z, are often heard imperfectly, and, though they appear to be audible, are really filled in by the listener. With normal hearing, moderately loud speech at an intensity of 60 decibels above the average threshold of audibility is intelligible to the extent of 95 per cent., while with very loud speech at an intensity of 70 decibels above the threshold vowels and consonants were perceived with approximately 100 per cent. of accuracy; but there was an increasing loss of distinctness when the intensity of the sound was raised further than this. Quantitative tests of hearing have been made on some 700 deaf children, with normal subjects as controls, by means of prepared lists of words transmitted at fixed levels of intensity through a high-quality amplifier in a sound-proof room. Children who have some residual hearing power—and they are very many—are taught to combine lip-reading and hearing to the fullest possible extent by means of suitable hearing-aid apparatus. But it is essential that the apparatus should be capable of high-quality reproduction, for any distortion is usually reflected in the children's own speech. The apparatus used contains four-stage valve amplifiers, and is not portable, since it has not been found possible to meet the requirements with the small portable hearing aids of wearable type. Three-quarters of the patients tested were severely deaf pupils from the Royal Schools for the Deaf, Manchester, or private patients. The remaining quarter were sent by school medical officers and other doctors. The latter can be divided into three groups: (a) The first comprised partially deaf pupils attending an elementary or private school who were reported as not making satisfactory progress, but whose speech and comprehension of speech appeared to be normal; in every case the degree of deafness shown accounted for the general backwardness. (b) Thirteen patients sent from schools for the backward or mentally defective were also tested, and in eleven of these there proved to be deafness to a degree sufficient to account for the retardation in speech, comprehension of speech and school subjects. It would seem very necessary that the hearing of all apparently mentally defective

children should be carefully examined. (c) Young children not yet attending any school. For these a series of tests with toys and objects has been devised, in which the young child learns in play to respond to certain sounds. In developing the hearing of children who are not completely deaf, an efficient hearing-aid apparatus is usually of immense help, but it is necessary that it should be used by teachers trained in the technique required for this specialised work. These methods usually bring about what can only be described as an extraordinary awakening of the mind, and Mr. and Mrs. Ewing report cases which show how shy and miserable children become cheerful and interested in school subjects. They are certainly justified in claiming that progress in learning to talk, and on every side, is more rapid and normal than it is when only the older means of teaching through sight and touch are used.

### THE DEATH OF A GRAMMARIAN

ALTHOUGH he was in his eightieth year the sudden death of Prof. Karl Pearson will come as a painful surprise to those who, in spite of arithmetical evidence, could not think of "K. P." as an old man or detect in his latest writings any sign of faltering. Championships are well enough in chess or boxing; they have no place in science or literature. It is idle—as K. P. himself would have said—to discuss whether this or that investigator was the greatest of his time. But it is safe to say that no English man of science of the last fifty years has more profoundly influenced the thought of his time. Most educated men and women over fifty will recall their first reading of the "Grammar of Science" as an event in their intellectual development, and to all who have had even the slightest contact with statistical science the name of Karl Pearson is a household word. Karl Pearson was indeed one of the last of the giants. It is probable that in any one of the fields of his activity, pure mathematics, mathematical statistics, philosophy, history, anthropology, eugenics, he has had contemporaries of equal or greater ability; it is certain that no individual has come nearer to the ideal of universal competence. There have been other men with the gift of inspiring enthusiasm in young workers, but none better endowed than Karl Pearson. And when one recalls that, as Johnson would have said, some anfractuosities of temper led "K. P." to reprove what he thought to be backslidings of his pupils with extreme severity, the fact that nobody who has ever worked with him will hear of his death without a painful emotion of bereavement is a proof of his unique power. When, nearly forty years ago, Karl Pearson opened the biometric campaign, statistical methods were almost unknown in the medical profession. There had been one or two great men in official service, such as William Farr and Shirley Murphy, who realised the power of the statistical method. The great Louis long before had perceived the importance of a numerical method to the clinician and William Osler had done something to popularise statistical tabulations. But the methods used were primitive and Pearson found little sympathy among brother mathematicians with his zeal to make mathematical methods available to those who had not been mathematically trained. He found even less readiness among members of our profession to welcome "mathematical" methods. It was almost common form in letters to or articles in the medical press for a writer to say that Prof. Pearson's work might be very interesting to "mathematicians, but——." By

sheer force of personality, "K. P." won his battle almost single-handed. He had indeed a little band of enthusiastic disciples, but he himself was always in the forefront of the battle. And an unfavourable criticism of the work of a pupil was sure to call forth a more trenchant counter-attack than any criticism of his own work. That he was always in the right, that all the methods he invented were useful, all the conclusions he reached correct, and all the opponents he trounced incompetent, nobody would maintain. Like the late Sir Victor Horsley—with whom he once raged battle furiously—he found it hard, in earlier years, to see both sides of a case. Almost the only sign of age noticeable in his later years was a mellowing in this respect.

His influence upon the medical profession has been almost wholly good. Wounds inflicted in controversial warfare have long been healed. The truths that when things *can* be measured and counted they *should* be measured and counted and that often in medical science things *can* be measured and counted much more often than we used to think, have been well learned. Much remains to be done, but, thanks to Karl Pearson, it is easier to do. Burke said that Chatham made the name of Englishman respectable upon the continent of Europe. Karl Pearson made the name of statistician respectable in medical circles. What Farr did for official statistics, Pearson did on a larger scale. There must be universal regret that he is no longer with us. But to pass away suddenly, still full of enthusiasm but conscious that the work he initiated will be continued, is a fitting close of an inspiring life.

### LONDON'S PRINCIPAL RHEUMATISM CLINIC

THE latest annual report of the British Red Cross Society's Clinic for Rheumatism, beside Regent's Park, is an account of services rendered and of aspirations to wider activity. The roll of new patients in 1935 was slightly smaller than in 1934, but the numbers of attendances and treatments are the highest so far attained by the Clinic; in the general out-patients' department there were 89,810 and 135,834 respectively, and in the private patients' department 8561 and 12,727. Mounting figures for attendance are not surprising, perhaps, in a clinic of only five years' standing. More remarkable is the fact that the patients discharged with treatment completed were almost as many as the new patients received, and that of the former 50.9 per cent. were cured or free from symptoms, 35.1 per cent. were definitely improved, 13.2 per cent. were unchanged or but slightly improved, and only 0.8 per cent. were worse. The work has increased in almost every department and new undertakings have been started; but any further development in the present building seems to offer considerable difficulty. The facilities for in-patient treatment at St. Stephen's Hospital, where the London County Council has set aside a number of beds for rheumatic patients, have been little used: the report points out that a considerable number of patients requiring in-patient treatment were unsuitable for admission to such a hospital and that for these there was little provision at the teaching and voluntary hospitals. Many were sent to the convalescent homes available, but the medical board think that better results could be achieved at a home especially designed for rheumatic cases. They state their need, therefore, of in-patient accommodation near the Clinic, where patients might be under the care of the visiting physicians, and of a

convalescent home with 20 beds and room for expansion.

Further provision, too, for research, they fairly claim, is essential if real progress is to be made in the treatment of rheumatism. During the year several books and papers have been published based on the results of investigations carried out at the Clinic, and work has been done on such subjects as the sedimentation-rate (as an index of prognosis and of the value of treatment); the treatment of menopausal arthritis; therapy with vaccines, gold, calcium, histamine, and ovarian preparations; colon irrigation; duodenal drainage; and various physical measures. It may be argued that the function of an out-patient clinic, well furnished with the apparatus of physical treatment, is to concentrate rather on therapeutics than on the wider problems of ætiology. But it is natural enough, no doubt, to find the staff of such a clinic yearning for the regular machinery of investigation—in-patient accommodation (with the chance of autopsy), the paid research workers, space for them to work in, and funds. The realisation of these hopes will presumably depend on the generosity of the public.

### TWO KINDS OF DIABETES?

THE history of diabetes during the last fifty years offers a good instance of how easily false conclusions can be drawn from biological data. The position of the pancreas in the ætiology of that disease was firmly impressed on the mind of the clinician by the observations of Minkowski and von Mering on pancreatotomy, and the much more recent discovery of insulin served only to strengthen the conviction. It was not until Houssay showed that the symptoms of experimental diabetes could be largely prevented by removal of the pituitary as well as the pancreas, that the pancreatic hypothesis of diabetes began to appear inadequate. The clinician has long recognised two distinct clinical types: a severe form occurring in young subjects, accompanied by wasting and gross ketosis, and a relatively benign form in older patients, in which glycosuria and its concomitant symptoms of thirst and pruritus are the presenting and sometimes the only features. The latter form has been from time to time attributed to some defect of carbohydrate storage, but on the whole the tendency has been to incriminate insulin deficiency in both forms. Elsewhere in this issue Prof. de Wesselow and Dr. Griffiths describe experiments which strongly suggest that the two forms may be ætiologically as well as clinically distinct. Their observations show that the blood of elderly diabetics contains considerable quantities of something which checks the development of insulin hypoglycæmia in rabbits. It is not yet clear what this substance is, but it seems to resemble extracts of the anterior lobe of the pituitary in its effect. This is perhaps the first direct piece of evidence to suggest that a common type of human diabetes may have nothing directly to do with the islets of Langerhans. It is interesting to note that patients in whom the unknown principle is present seem to belong to the group which Himsworth<sup>1</sup> describes as "insulin-insensitive." Himsworth attributes this insensitivity to lack of an unknown factor which sensitises the body to insulin. It is difficult to accept both of these two apparently contradictory views, but further knowledge will no doubt reconcile them. Observations of this kind should stimulate others to pay less attention to the

pancreas and more to other endocrine organs in diabetes. It has become almost a platitude to say that no ductless gland can be considered apart from the others. But the general tendency to pin a disease to one gland dies hard.

### INCIDENCE OF POST-VACCINAL ENCEPHALITIS

THE March issue of the *Bulletin* of the International Office of Public Health contains the following information about the recent incidence of post-vaccinal encephalitis in various countries. In Germany 4 cases are reported among 1,200,000 children vaccinated in the course of 1935. A few cases of encephalitis were also observed after vaccination in which it was suggested that activation of a tuberculous infection might be responsible. In England during the period October, 1934, to October, 1935, there was only a single case, which ended fatally, the patient being a woman aged 20. The necropsy revealed characteristic lesions in the brain. In the United States also only a single case was notified during the financial year 1934-35. In Holland, among the 4 patients examined by the neurologists specially appointed for the purpose, the diagnosis was in 2 uncertain and in 1 improbable. The last case was that of a child of 9 months who developed symptoms of encephalitis 28 days after vaccination. Only 17,000 vaccinations were performed in Holland during 1935, so that the proportion of encephalitis cases (1 per 5000 vaccinations) differed little from what it was in previous years. There were only 2 mild cases during 1935 in Sweden, where there have been no deaths due to post-vaccinal encephalitis since 1932. In Switzerland there were 2 cases in 1935 among about 35,000 vaccinated children. These figures show that the incidence of encephalitis after vaccination has been tending to fall in the countries most affected, except perhaps in Holland.

THE biennial dinner of the Royal Society of Medicine will be held on Wednesday, May 6th, at 7.30 for 8 P.M., at the May Fair Hotel, Berkeley-square, London, W.

Dr. J. Godwin Greenfield is to deliver the Morison lectures at the Royal College of Physicians of Edinburgh on Monday, Wednesday, and Friday of next week, at 5 P.M. His title is the Cerebro-spinal Fluid: Some Modern Problems.

WE regret to learn of the sudden death on Monday last of Mr. Albert Carless, consulting surgeon to King's College Hospital and editor of the manual of surgery, originally written in collaboration with the late Mr. William Rose, which maintains under recent editorship its authoritative position.

INSTITUTE OF MEDICAL PSYCHOLOGY.—A week-end course on psychological disorders in childhood will be given on May 9th and May 10th at this institute, Malet-place, London, W.C. Further details may be had from the educational secretary, and the full programme is given in our Medical Diary.

CHILD GUIDANCE COUNCIL.—Three fellowships in psychiatry are offered by this council for half-time work at the London Child Guidance Clinic in Islington. Further information will be found in our advertisement columns, and forms of application may be had from the secretary of the council, Woburn House, Upper Woburn-place, London, W.C.1.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

### XCIX.—PROGNOSIS IN ARTHRITIS

To the lay mind the prospect before the patient attacked by arthritis of any kind is one of pain, crippling, and deformity, with little or no prospect of relief. Such a prognosis is not justified; in a few cases the disease becomes stationary and dies out without any special treatment, and in a large proportion steady perseverance with appropriate measures will lead to the same result, though if care has not been taken to counteract the effects of muscle spasm or atrophy some deformity will persist. In a few cases, probably less than 10 per cent., the disease follows a relentless course to complete crippling before it burns itself out.

The prognosis in osteo-arthritis is essentially different from that of rheumatoid, and all the cases included under the latter head do not present the same characters or tend to run the same course.

Age has a bearing on the incidence and course of both types, but it must be remembered that though rheumatoid arthritis is generally a disease of young adults it may appear later in life, and the condition is not infrequently seen beginning in the sixties or even later; while the first signs of osteo-arthritis may appear in the late thirties or early forties. To draw a sharp distinction may indeed be difficult, for the hypertrophic changes of osteo-arthritis, the formation of osteophytes, and the increase in the density of the bones as shown by the X rays are sometimes the late result of an arthritis of infective origin or of gout, and are in the nature of a reparative process, nature's method of reinforcing weakened ligaments where the active disease has died out. On the other hand, they may indicate a degenerative process due to lowering of local or general resistance to ordinary wear and tear, accelerated perhaps by toxic absorption, and mixed cases are not uncommon in the middle years from such causes. In this group should be included the so-called climacteric arthritis which attacks knee-joints in middle-aged women and here an endocrine deficiency probably plays a part of some importance.

#### Rheumatoid Arthritis

Rheumatoid arthritis is probably the result of a low-grade infection due to a relatively non-pathogenic microbe which has been enabled to attack the joints or other structures by reason of some factor lowering resistance or possibly sensitising the tissue cells to the specific infective agent. Such factors are to be looked for in the conditions of life, unhygienic dwellings or occupations, unsuitable diet due to poverty or to wrong ideas and tastes, excessive fatigue with lack of fresh air and recreation, nervous strain or shock due to prolonged anxiety, bereavement, and so forth. Sensitisation may result from septic foci of long standing, and it must be remembered that if from any cause resistance is lowered, tissues other than the joints may be attacked and pyorrhœa, for example, may be set up side by side with the arthritis and not (as is often supposed) be in itself the main ætiological factor. The general build of the patient must not be overlooked as a prognostic guide; the slender, flat-chested visceropototic type with defective circulatory tone, poor capillary circulation, cold hands and feet, probably chronic constipation and frequently achlorhydria, capricious appetite, and poor digestion is especially liable to develop arthritis of a

severe type. Upon a properly directed and vigorous attack on such predisposing factors the prognosis will materially depend. The one indisputably sound line of treatment in all cases is to raise the patient's resistance to a point which will enable the infection to be overcome, and the principles which have revolutionised the prognosis and treatment of tuberculosis must be applied in rheumatoid arthritis. The earlier the patient is brought under the influence of treatment along these lines the better the prospect is likely to be, but even when the disease has become well established arrest, if not cure, can be looked for in a large proportion of cases.

#### GENERAL MEASURES

Rest should be the key-note. In early cases, in those with pain and swelling of joints of any severity, in those with pyrexia however slight, in fact in all in which the disease is definitely active, this will mean bed for most of the day and often all the time for some weeks. The inflamed joints should be put up in plaster for a short period (not less than two nor more than six days) when the plaster should be bivalved to permit of gentle movement, preferably active rather than passive, in order that circulation and muscular tone may be improved. The splints must be worn at night and often for much of the day as well in order to counteract any tendency to deformity. With rest must be combined suitable diet on the general principle of moderate restriction of carbohydrates, but free consumption of milk, cream, eggs, meat, vegetables, and fruit, aiming at an ample but balanced vitamin supply, for which purpose cod-liver oil will be found a useful addition. Suitable physical treatment to treat constipation, to improve the peripheral circulation, and to re-educate the muscles is also essential and with perseverance along these lines great improvement is likely to be obtained and the patient prepared for further treatment if necessary.

Pemberton's figures of a series of patients with both types of arthritis at all stages who were placed on this line of treatment are remarkable: of 300 cases 89 per cent. were improved, 57 per cent. "definitely," and 32 per cent. "greatly"; 6 per cent. were cured (Jour. Bone and Joint Surgery, xvii, 4, 879). The proportions were similar in both types of arthritis and many of the patients had tried many other lines of treatment before this régime was instituted.

#### SUBSIDIARY MEASURES

The treatment of *focal sepsis* cannot be ignored but will be more effective and less liable to untoward results if carried out in connexion with the general treatment outlined above. Sometimes the removal of teeth or tonsils is followed by most remarkable improvement or even cure, but occasionally by a temporary increase in symptoms due to absorption of toxic material from the raw surfaces. The removal of septic foci can rarely be complete, but if the major ones are adequately dealt with the improvement in resisting power from general measures will keep the minor ones in check and the microbes may continue to exist as saprophytes until some circumstance leads to a renewal of their activity. The joints themselves may be the foci from which a fresh general infection develops. The importance of a

chronic inflamed gall-bladder or appendix must not be overlooked.

It is outside the scope of the present article to discuss the value of vaccines in any detail, but in view of their wide use it is necessary to say that vaccines have in many cases done much more harm than good, chiefly through excessive dosage. It may, in my opinion, be laid down as a principle that any reaction to vaccine is an indication for reduction of dose to a level which produces no reaction. Vaccines should be used as desensitising agents, and the best results may be obtained by a progressive reduction in dosage rather than by increase. Large doses may sensitise the tissues, lower the resistance, and thus cause the disease to become rapidly worse. By the use of minimal dosage no harm is likely to result; and even if there is no evident specific effect the patient feels that a definite line of treatment has been thought out and is being pursued, and gains encouragement from this fact and with it a real increase in power of resistance. One American authority of wide experience has said that though he is doubtful if vaccines have any specific effect he uses them in small doses in order to keep the patient under continual observation, and thus to be able to direct and control a general line of treatment.

*Gold treatment* is another method holding out definite prospect of good results if used cautiously, but it has often in the past been given in too large doses without sufficient precautions, and has thus fallen somewhat into discredit.

The *course of the disease* in all its forms is often characterised by remissions in the symptoms without any obvious cause; pyrexia especially is apt to be variable. The attack may appear to subside, the joints become less painful and swollen, and in early cases there may be an apparent recovery only to be followed by a fresh outbreak which may not subside until the joints have been permanently and seriously damaged. Such relapses may be caused by excessive fatigue, anxiety, or any depressing influences such as an attack of influenza or similar disease. Patients should, therefore, be kept under observation for months after the disease appears to have become stationary, and warned to lead a careful life on lines laid down for each case. The administration of cod-liver oil, especially during the colder months is, in my experience, a most useful measure. Apart from its effect on nutrition it lessens the liability to catarrhal attacks which are so often followed by recrudescence of the arthritis.

An *optimistic attitude* on the part of the doctor is a factor of much importance; the effect of depressing influences such as a lack of therapeutic resource does much to weaken the patients' power to fight the disease.

#### PROGNOSIS AS REGARDS MOBILITY

In most of the cases treated on the above lines by splinting and rest together with local heat, massage, and re-education of the muscles, there will be little deformity, but in a small proportion of them this happy result will not be obtained, and further measures will be required.

The characteristic deformities are due to contraction of the joint capsule or to adhesions between the joint surfaces, together with malposition induced by atrophy of some muscles and overaction of their opponents. Though rest is enjoined, movements should be carried out from the beginning in a systematic manner once or twice a day and should be active whenever possible, as this will help to maintain the tone and nutrition of the muscles. Massage

will aid in this direction, but it is better not to massage the joints themselves though very light friction with analgesic liniments may be permitted.

*Knee and hip-joint.*—The knees are often kept slightly flexed, as this is the most comfortable position for the patient, and there is consequently a danger of loss of full power of extension through contraction of the posterior ligaments. Weight extension will overcome this, if applied early, and is often effective in relieving pain both in knees and hips by keeping apart the inflamed articular surfaces while permitting movements to be carried out. When this can be dispensed with a light splint should be worn at night for a time. If straightening cannot be effected by these means the use of a succession of light plaster shells to support the joint, at each stage being made a few degrees straighter as the limb accommodates itself to the support, may prove successful. In more severe cases the operation of synovectomy may be employed, especially if there is a thickened and painful synovial pad behind and around the patella. Where the defect is due to contraction of the posterior ligament a plastic capsulectomy is sometimes useful. As a last resort, excision of the joint and fixation in a straight position may have to be adopted.

Forcible movement of joints under an anæsthetic is always accompanied by the risk of waking up the acute process which had become quiescent. It is obviously of no service where bony ankylosis or much thinning of the cartilage is evident from a radiogram, but in early cases where limitation of movement has resulted from adhesions and capsulitis the results may be very satisfactory.

The same principles apply to the treatment of *other joints*. There is difficulty in maintaining full and regular movement in an inflamed shoulder or elbow, and excision of the joint may become necessary if ankylosis occurs in such a position that the hand cannot be brought to the mouth. Pronation and supination may be restricted by adhesions in the radio-ulnar joint or in the wrist. The wrists are very frequently the seat of arthritis and rarely escape some restriction of movement, but much can be done for them by such measures as have been described. Light cock-up splints to be worn at night are often desirable. It is necessary to remember that a stiff wrist may be more useful than a weak one resulting from forced movement. If support is needed when the patient resumes walking elbow crutches are preferable to sticks, which throw a strain on the wrists and tend to cause pain and distortion as well as a faulty carriage of the body. When the ankles are affected care must be taken to avoid foot drop while the patient is in bed. When the mandibular joint is affected a screw wedge, which should be used by the patient himself, will help to secure better movement. For the fingers special splints have been devised to apply traction, but good results may be obtained by a little ingenuity with elastic bands. Occupational therapy is often of great assistance if carefully devised and directed.

*Local heat* will help as a preliminary to movement, and moist heat is often more effective than dry. Hot baths, both local and general, with the addition of common salt, soda, or Epsom salts often give much relief, and movements can be carried out more easily when the limbs are supported by water. Poultices are useful for knees and elbows, and these simple measures are often more useful than more

## SPECIAL ARTICLES

## PAGET'S DISEASE OF THE NIPPLE

By J. PATERSON ROSS, M.S., F.R.C.S.

PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON  
DIRECTOR OF THE SURGICAL PROFESSORIAL UNIT,  
ST. BARTHOLOMEW'S HOSPITAL

The clinical features of Paget's disease of the mammary areola are well recognised, but the views held with regard to its pathology are often vague or erroneous. In spite of painstaking research by Cheate and by Muir, some text-books are still disseminating misleading and fallacious opinions about the relationship of Paget's disease to carcinoma of the breast, and it has even been suggested that the skin lesion may not be a pathological entity. Such misconceptions and the consequent uncertainty about the treatment of Paget's disease must be the excuse for this brief review of the subject.

## IS PAGET'S DISEASE A PATHOLOGICAL ENTITY ?

Paget's disease of the nipple is frequently referred to as "eczema," but it differs from simple dermatitis in that it does not spread beyond the areola, it is resistant to all methods of treatment, and it has a characteristic histology, the epithelium containing numerous large clear vacuolated cells which are not found in simple inflammatory lesions of the skin. It must be understood that Paget's disease is not peculiar to the skin of the nipple, and Susman has collected 34 cases which occurred in other parts of the body, most commonly on the skin of the perineum and external genitalia.

Susman (1928) laid special stress on Paget's disease of the glans penis, describing a case of his own which he added to 6 others which had been described previously. Though the clinical details of some of these earlier cases are incomplete it is clear that the nature of the lesion was well established, and in all of them there was a red moist shiny area surrounding the external urinary meatus. The average duration of the disease before the patients presented themselves for examination was two years, and in none of the records is there any mention of previous lymphatic obstruction or oedema. In 3 cases, it is stated, the neighbouring lymphatic glands were not involved late in the disease. Most of the notes refer merely to diagnosis and only 2 record the late results of treatment. In both these cases partial amputation of the penis was performed, and though the patients seemed to do well for a time they eventually died of uræmia resulting from carcinomatous stricture of the remaining portion of the urethra. The illustrations accompanying this article show that the macroscopic and microscopic appearances of Paget's disease in this situation are identical with those of Paget's disease of the nipple.

The term *dermatitis maligna* has the virtue of pointing out that Paget's disease of the nipple is

(Continued from previous page)

elaborate methods, with the advantage that they are inexpensive and available in every household, a matter of importance when treatment must be carried on for many months. The utmost perseverance will be demanded from doctor and patient, and if this is forthcoming the improvement will often astonish both.

C. W. BUCKLEY, M.D., F.R.C.P.,

Hon. Physician, Devonshire Royal Hospital, Buxton,  
and to the Buxton Clinic for Rheumatic Diseases.

(To be continued.)

malignant. But to call it "dermatitis" is a misleading half-truth, for although there is an inflammatory reaction in the cutis vera of the areola, this term suggests that the disease is confined to the skin, whereas similar changes are occurring simultaneously in the epithelium of the ducts of the breast.

## IS PAGET'S DISEASE A COMPLICATION OF A SUBJACENT CARCINOMA OF THE BREAST ?

The title of Paget's original paper in St. Bartholomew's Hospital Reports, "On Disease of the Mammary Areola preceding Cancer of the Mammary Gland," might be regarded as a sufficient answer to this question. Further inquiry, however, is called for, since there are still many teachers who cling to the hypothesis that the skin lesion is a sequel to a carcinoma beneath the nipple, being the result either of blockage of skin lymphatics by permeation, or of irritation of the surface epithelium by cancerous exudates.

Clinical records are unanimous in stating that the nipple lesion is present for a long period, sometimes for many years before carcinoma is palpable in the breast. In support of Paget's own statement to this effect there is a series published by Bowlby in 1891 in which out of 22 patients 9 showed no tumour in the breast when they presented themselves for treatment many months after the onset of the disease. During the ten years 1925-35 there have been 8 cases of Paget's disease of the nipple in the wards of St. Bartholomew's Hospital, and in 6 of these a tumour could not be felt in the breast.

## CASE REPORTS

1. A. B., aged 63. Single. June, 1923, eczema of the right nipple. March, 1925, breast excised. Section of nipple showed Paget's disease, but no carcinoma could be found in the breast. The patient died in 1934 without recurrence of disease.

2. C. D., aged 61. Single. December, 1924, eczema of right nipple. February, 1926, breast excised. Section of nipple showed Paget's disease, but no carcinoma could be found in the breast. Patient cannot be traced.

3. E. F., aged 66. Married, five children. May, 1925, eczema of the right nipple. November, 1926, nipple destroyed but no lump palpable in the breast. Breast excised. Section of the nipple showed Paget's disease, and dilated ducts were found deep to the nipple. A focus of spheroidal-celled carcinoma was discovered histologically. May, 1929, recurrence of carcinoma in scar; February, 1931, died with metastases in liver.

4. G. H., aged 58. Married, two children. June, 1927, eczema of the right nipple. June, 1930, nipple replaced by sore area, but no lump palpable in breast. Breast excised. Section showed Paget's disease of the nipple, and the ducts close to the nipple showed dilatation and cellular hyperplasia but no carcinoma was found. October, 1935, spheroidal-celled carcinoma appeared in the scar and in the right axillary glands.

5. I. J., aged 68. Single. January, 1927, eczema of the right nipple. July, 1929, nipple partially destroyed but no lump palpable in breast. Section from nipple showed Paget's disease. Three radon seeds (1.5 m.c.) inserted deep to nipple. September, 1929, nipple lesion healed. December, 1931, no evidence of disease on nipple or in breast. Patient cannot be traced.

6. K. L., aged 55. Married, no children. July, 1934, eczema of the right nipple. February, 1935, nipple destroyed but no lump palpable in breast. Section of nipple showed Paget's disease. Enlarged supraclavicular gland excised and found to be carcinomatous. X ray treatment to chest, but in July, 1935, the patient died with visceral deposits of carcinoma.

The tumour when it does appear may be found in any part of the breast, and is frequently remote from the nipple; there is no statistical evidence to favour the view that Paget's disease occurs when the tumour is closely related to the areola. Further, it is significant that no mention of pre-existing subjacent carcinoma has been made in the accounts of Paget's disease in other parts of the body.

A superficial carcinoma of the breast infiltrating the skin may resemble Paget's disease clinically, but histological examination reveals the true nature of the disease. This difficulty has not always been recognised, even in publications, and is undoubtedly responsible for some of the existing confusion.

On anatomical grounds it is hard to understand how a growth deep to the nipple could block the lymphatics of the areola, from which drainage is provided by vessels which run over the surface of the breast to enter the deep lymphatics at its periphery. The characteristic *peau d'orange* resulting from lymphatic blockage is associated with extensive disease in the breast, and is always regarded as one of the most serious features influencing the prognosis of carcinoma. But it cannot be too strongly emphasised that *peau d'orange* is neither a precursor nor even an accompaniment of Paget's disease.

The discharge which sometimes occurs from the ducts in chronic mastitis can cause simple eczema of the nipple, but there is no evidence that Paget's disease can result either from such a discharge or from the exudate of a carcinoma. If it were so Paget's disease might be expected to be more common. Injury and simple inflammation of the nipple do not seem to be factors, since Paget's disease occurs with equal frequency in women who have and those who have not borne children.

#### IS PAGET'S DISEASE OF THE NIPPLE FOLLOWED BY CARCINOMA OF THE BREAST?

Though a variable and often a long period of time may elapse between the appearance of the nipple lesion and the discovery of a tumour in the breast this question must be answered by an emphatic affirmative. Both Cheatle and Muir have given detailed descriptions of the hyperplastic changes in the epithelium of the ducts which are always to be found in cases of Paget's disease. The histological changes observed in the epithelium of the nipple and of the ducts are essentially malignant in nature.

Muir believes that the disease commences as carcinoma in the ducts close to their orifices, and that the nipple is involved by intra-epithelial infiltration from them. Cheatle regards the cellular phenomena in the skin and the ducts as the response to a common carcinogenic agent. If the fundamental conception that there is malignant disease in both situations be accepted, the question of their exact interrelationship may be regarded as a matter more of academic interest than of practical importance. The occurrence of Paget's disease in other parts of the body suggests that the production of the superficial lesion is not dependent upon the extension of a neoplastic process originating deep to the skin.

Cellular hyperplasia extends deeply into the breast along the ducts and, though malignant from the start, growth is confined for a time within their epithelial lining. Eventually, however, these abnormal cells burst through into the breast substance, it may be at a considerable distance from the nipple, and a carcinoma develops which resembles in every respect, both in its morphology and in its natural history, the usual carcinoma of the breast. The cellular

changes in the ducts and the earliest stages of the resultant carcinoma are clinically impalpable, and it is therefore possible for metastasis to occur before a lump is discovered in the breast.

The intimate relationship between Paget's disease and carcinoma is not confined to the breast, and both Paget and Susman refer to carcinoma of the urethra following Paget's disease of the glans penis.

#### HOW SHOULD PAGET'S DISEASE OF THE NIPPLE BE TREATED?

Experience has shown that excision of the nipple is futile, and though excision of the breast alone may sometimes eradicate the disease, complete removal of the breast, pectoral muscles, and axillary glands is the safest method of treatment. Thorough irradiation of the whole breast and the areas of lymphatic drainage may be considered as an alternative, but when the primary growth cannot be identified as a circumscribed lump radium treatment is less satisfactory than amputation of the breast.

Study of the eight cases already mentioned is instructive, for in three the treatment adopted was simple excision of the breast. There was no tumour to be found in the specimens after operation. One patient lived for nine years and died of heart failure; one cannot be traced; but the third returned five years after operation with spheroidal-celled carcinoma in the operation scar and in the axillary glands. A tumour was found in the breast after operation in two cases. In one of these the patient was treated by radical amputation of the breast, pectoral muscles, and axillary glands, but five years later she died with visceral deposits of carcinoma; and in the other the breast and lymphatic areas were irradiated, the disease of the nipple and the lump in the breast disappeared, but the patient died with visceral metastases two years later. One patient who was very obese had Paget's disease of the nipple, a lump could not be felt in the breast, but an enlarged supraclavicular gland was found to be filled with spheroidal-celled carcinoma. The breast, axilla, and mediastinum were treated with X rays but she died six months later with cerebral metastases.

It seems justifiable to conclude from such experiences and from the results of pathological research that Paget's disease of the nipple is evidence on the surface of an associated carcinomatous process in the breast; and since this deeper process can spread into the breast substance and even to the nearest lymphatic gland before there is any palpable evidence that it is no longer confined within the epithelial lining of the ducts, the disease must be treated by immediate radical removal of the breast with the axillary glands.

Complete and beautifully illustrated descriptions of the pathological changes which occur in the skin and in the ducts of the breast are given in the following articles:—

---

LOWESTOFT AND NORTH SUFFOLK HOSPITAL.—There is a nursing staff here of 32 nurses but only 30 beds for their use, so that unless two nurses are always away on leave, beds must be hired outside the hospital. An appeal for £20,000 is being launched for the provision of a nurses' hostel and other improvements to the hospital.

## RADIOLOGY IN THE CURRICULUM

THE section of radiology of the Royal Society of Medicine, which has been considering the place of radiology in the medical curriculum, has now sent in its recommendations to the curriculum committee of the General Medical Council. These recommendations are based on a report to the section of a committee made up of Dr. F. M. Allchin, Mr. J. F. Carter Braine, Mr. Rock Carling, Dr. N. S. Finzi, Prof. F. R. Fraser, Dr. F. Hernaman-Johnson (chairman), Dr. G. Harrison Orton, Dr. Russell J. Reynolds, Dr. C. G. Teall, Dr. E. W. Twining, and Dr. Douglas Webster.

### Recommendations

I. Instruction in the physics of radiation should be given in the preclinical period.

II. Radiology should be utilised where practical in the teaching of anatomy, physiology, and pathology.

III. Instruction in the scope of X rays in diagnosis, and of X rays and radium in treatment, should be required during the clinical period of the curriculum. This may be accomplished by :

(a) Combined teaching by clinician and radiologist in ward rounds at the invitation of the physician or surgeon.

(b) The radiologist conducting demonstrations in the X ray department on selected films. Physicians and surgeons should attend these demonstrations and take part in the discussions.

(c) A number of lecture-demonstrations by a radiologist being included in the courses of lectures on medicine and surgery.

(d) The formation of an exhibition of radiograms illustrating typical cases.

The scheme adopted can best be left to the individual schools to decide upon, but a combination of either (a) or (b) with (c) and (d) would be most satisfactory. No opinion is offered as to the precise amount of time which should be spent on the teaching of radiology ; a schedule sets out the wide differences in the time devoted to organised teaching in British schools to-day. In some schools instruction is given in diagnosis only, in others in radiotherapy only ; any regulations which are framed should specify instruction in both divisions.

### Summary of Present Position at Home

RADIOLOGICAL ANATOMY is now taught to undergraduates at :

- University College Hospital.
- St. Thomas's Hospital (one hour daily by X ray assistant).
- St. Bartholomew's Hospital (about 30 lectures).
- Guy's Hospital.
- Oxford.
- Cambridge (and with physiology).
- St. Andrews.
- Dundee.
- Manchester.
- Birmingham.

LECTURE COURSES in radiology are given to undergraduates at :

- London Hospital (weekly through final year, and ward demonstrations).
- St. Mary's Hospital (11 lectures in autumn term, demonstrations in X ray department).
- Middlesex Hospital (11 lecture-demonstrations in autumn term).
- Charing Cross Hospital (6 to 8 lectures).
- St. George's Hospital (short course of lectures, and frequent demonstrations).

King's College Hospital (3 or 4 introductory lectures —supplementary course later).

St. Bartholomew's Hospital (3 lectures in therapy only).

Guy's Hospital (8 lectures in diagnosis only).

Liverpool (11 lecture-demonstrations).

Manchester.

Leeds.

Durham (6 lectures each term).

Dundee (occasional lectures, with clinical medicine course).

Glasgow (20 meetings and demonstrations).

Birmingham.

ATTENDANCES in the X ray department are required of undergraduates at :

Charing Cross Hospital (3 months as clerk).

Royal Free Hospital (1 month as clerk).

University College Hospital (a fortnight as clerk).

Westminster Hospital (12 attendances).

(In these hospitals attendances are all compulsory ; students must be signed up.)

St. Thomas's Hospital (demonstrations).

Middlesex Hospital (clerks appointed).

### And Abroad

For comparison a summary is appended of instruction in radiology as at present given in the United States of America and in Sweden.

*United States of America.*—There are 53 Class A medical schools, in about half of which instruction in radiology is given in the second year (average 10 hours) with anatomy and physiology. In 80 per cent. in the third year (average 30 hours), a general exposition of roentgenology. In 98 per cent. in the fourth year (average 25 hours), clinical applications. And in 42 per cent. laboratory courses are given in addition to the lectures.

*Sweden.*—Compulsory course : one term in X ray diagnosis (about 20 hours, lecture-demonstrations). Optional course : for eighth to tenth year students, 2 months' course (about 44 hours, X ray diagnosis and X ray and radium therapy).

## MEDICINE AND THE LAW

### Litigation Over Sale of Practice

IN litigation over the sale of a medical practice (With *v. O'Flanagan*) the Court of Appeal last month gave a decision which is likely to be noted in the text-books on the law of contract. It was a London practice, carried on at two different premises. The prospective purchasers naturally obtained information beforehand about the value. They were told that the practice had produced £2000 a year and that the number of panel patients was 1480. They agreed to pay £4000 (two years' purchase) as the price of transfer. The date for completing the contract of purchase was May 1st, 1934. During the four months preceding that date the vendor was obliged by illness to be absent from his work. He managed to return occasionally and worked for about 30 days at one of the premises ; meanwhile the practice was carried on by other doctors acting as locum tenens. One of the latter, who was acting from April 10th to May 1st, gave an account of the practice which showed that conditions had changed since the figures had originally been given to the purchasers. The average takings were said to be as low as £5 a week, and the panel patients had dropped to 1250. The vendor became very ill and died. The purchasers, finding that they had bought something which was worth very little, brought proceedings

against his executors, asking for rescission of the contract. Mr. Justice Bennett held that the vendor had been aware of the altered value of the practice and that the purchasers had not been told of the change. But he dismissed the claim for rescission, apparently on the ground that the representations were true at the time when they were made and that the buyers had no legal right to be told of the altered value.

Some observations of Sir Edward Fry in *Davis v. London and Provincial Marine Insurance Co. (1878)* seem material. When parties contract with one another, he said, they may (unless there is a duty to disclose facts) observe silence even as to matters which each thinks would operate on the other's mind. There is, however, a duty to disclose when an agent is contracting with his principal, a solicitor with his client, a guardian with his ward, or a trustee with the person towards whom he stands in a fiduciary relation. The agent, solicitor, guardian, or trustee can in these circumstances contract only after the most ample disclosure. Then there are contracts sometimes called contracts *uberrimæ fidei* (of the utmost good faith) where the courts will specially require disclosure from one of the contracting parties—such as contracts about marine insurance or partnership. Lastly, in ordinary contracts the duty of disclosure "may arise from circumstances which occur during the negotiations. If a man makes an honest misstatement of fact on some material point and during the negotiations he discovers it is wrong, he has a duty to correct his misstatement, although, if he had never said anything at all, he might have been entitled to hold his tongue." So again, continued Sir Edward Fry, "if a statement has been made which is true at the time, but which during the course of the negotiations becomes untrue, then the person who knows that it has become untrue is under an obligation to disclose to the other the change of circumstances." Following these views the Court of Appeal has overruled Mr. Justice Bennett. The judges say that the change in the circumstances of the practice ought to have been communicated to the prospective purchasers before they were allowed to close the transaction. The contract could not stand. Put in another way, the representation about the value of the practice, which had induced the purchasers to enter into the contract, was a continuing representation. As was remarked in the old case of *Kay v. Smith*, "the representation does not end for ever when the representation is once made; it continues on." The Court of Appeal has now decided that the purchasers are entitled to a declaration rescinding the contract of purchase. It is a situation which might often be created on the transfer of a practice.

#### Penal Servitude for Bogus Doctor

Edward Waugh Atkinson, aged 51, a male nurse, pleaded guilty at the Central Criminal Court last week to a charge of obtaining £124 10s. by false pretences, and was sentenced to five years' penal servitude. Though he was apparently not charged with infringing the Medical Act, he had assumed the description of doctor in order to impose upon his victims. He caused telegrams to be sent to himself describing him as possessing medical qualifications; he borrowed £10 to buy a stethoscope, and he introduced himself as a doctor. He even gave surgical treatment to a woman from whom he obtained £44, extracting pieces of bone from her injured shoulder. The prisoner asked that four other outstanding charges might be taken into account. The police

told the court that he had seven previous convictions, including two terms of penal servitude. In passing sentence the Recorder referred to him as a menace to the public.

Some people may draw the moral that any untrained person can perform a surgical operation with success. Others may deduce that the Medical Act is not without its value. Apart from any question of professional training, the presence of a name on the Medical Register is some evidence of the owner's non-criminal character. Those who summon a registered practitioner to their houses need not, we hope, lock up the spoons.

## SCOTLAND

(FROM OUR OWN CORRESPONDENT)

### DIMINISHING PRIVATE PRACTICE

THE increasing number of patients who attend for treatment at the Glasgow Ear, Nose, and Throat Hospital has necessitated the building of an extension which will cost about £25,000. Comparison with the figures of eight years ago shows that the number of patients attending the hospital for treatment has increased by 34 per cent.; in 1935, 14,746 new patients received treatment. In moving the approval of the medical report, Dr. John Dunbar said that the medical staff must view the growing attendances in no very favourable light. It meant that the medical staff must be increased to cope with the position and showed that the scope of private practice was becoming steadily less. He said that the surgical staff did not object to treating patients who could not afford to pay, but they did object to being exploited. Dr. Hinton Robertson, who seconded the motion, said that there was a large and growing body of opinion in the medical profession, particularly among the younger generation, which was uneasy about the present trend towards hospitalising increasing numbers of the sick population. This would lead to an economic deadlock, for the hospitals would require so many doctors to carry on the work that they would be far in excess of the number that could be maintained by the remaining private patients. As it is, the profession has tended in recent years to incur a certain amount of odium because pressure of circumstances had converted its members into Robin Hoods who rob the rich to pay the poor.

The exploitation of the voluntary hospital by many who are able to pay for medical attention is becoming increasingly apparent. The number of medical and surgical specialists has to be increased to meet the extra work, while the scope of private practice is steadily diminishing. The payment of the staffs in voluntary hospitals seems to be an inevitable result that should not be much longer delayed. The appointment of almoners who can investigate the income of patients attending hospitals has become a real necessity.

### CHAIR OF DENTISTRY

At a meeting of the university court of St. Andrews it was announced that a sum of about £17,500 has been offered to the University towards the establishment of a chair in dentistry. The donor is Mr. William Boyd who has already subscribed liberally towards improvements in the Dundee dental hospital, and his offer was gratefully accepted by the court. The annual income of the sum provided will amount to about £500 per annum.

## IRELAND

(FROM OUR OWN CORRESPONDENT)

## UNIVERSITY REPRESENTATION IN DÁIL EIREANN

LAST week the Dáil took the final step in the abolition of university representation in that assembly. It is nearly two years since the Bill passed the Dáil, and was rejected by the Senate. The power of the Senate, however, is only to hold up a Bill temporarily, not to reject absolutely, the period of suspension being limited to eighteen months. At the expiration of that period early this year the Bill was again sent up to the Senate which gave it a second reading, but amended it by introducing a section which postponed its coming into effect until six months after the next general election. The Dáil refused to assent to the amendment, and last week exercised its power by resolution of "deeming the Bill to be passed by both Houses" when the period of six weeks had elapsed from the second reading of the Bill from the Dáil to the Senate, and the latter body had not passed it. The Bill now becomes law on receiving the signature of the Governor-General. There are two universities in the Irish Free State,

the University of Dublin (best known as Trinity College, Dublin) and the National University of Ireland. Dublin University has had the privilege of representation since 1613, a little more than twenty years from its foundation. Its members sat in the Irish Parliament up to the date of the Union in 1800, from which time until 1921 they sat at Westminster. The National University was first given the right of representation in 1918. By the Constitution of the Irish Free State which came into force in 1923 each university was privileged to return three members. At present Dublin University is represented by two fellows of Physic College and a professor of the School of Trinity; the National University is represented by two barristers and a writer. The Bill does not become effective until the next general election.

## DEAN OF THE SCHOOL OF PHYSIC, TRINITY COLLEGE, DUBLIN

Dr. Joseph Warwick Bigger, professor of bacteriology and preventive medicine since 1924, has been appointed dean of the medical faculty, Trinity College, Dublin, in succession to the late Prof. A. F. Dixon. Dr. Bigger has also succeeded Dr. Dixon as representative of the University of Dublin on the General Council of Medical Education and Registration.

## PANEL AND CONTRACT PRACTICE

## Drugs in Lancashire

WE have repeatedly referred to the growth in Lancashire of the habit of taking medicines. The insurance committee has had a report prepared on the cost and frequency of prescribing during the year 1935. This report quotes the opinion of the C.M.O. of the Ministry of Health that, while a certain increased demand is to be expected from the extending use of costly, though necessary, modern methods of treatment, a considerable proportion of the total outlay on drugs could be eliminated without detriment. Nor can he find evidence that the standard of health is higher in areas where the habit of taking medicines is highly developed. The report points out that during the last five years only one doctor under agreement with the Lancashire committee has been surcharged on the grounds of excessive prescribing; indeed, since the inauguration of the present system twelve years ago, money has been only withheld on four occasions. During the same period the cost of drugs has increased from 34 to 41 pence per person per year, and the number of prescriptions from 3.87 to 5.05. In the seven regions into which Lancashire (apart from its county boroughs) has been divided by the Ministry of Health for the purpose of investigation, the estimated average total cost of drugs per insured person varies from 37.36 to 51.45 pence while the number of prescriptions ranges from 4.74 to 6.14. It is curious to note that the average drug cost in non-mortgaged practices in Lancashire is 40.78 pence, against 44.23 in mortgaged practices. There are fortunately six times as many insured persons in the former category. Practitioners with colonial qualifications, it seems, show a rather heavier return than home-qualified men, while those who have qualified between 1926 and 1935 are definitely more generous with drugs than their elders. It might have been anticipated that small lists would show a heavier average drug cost than the larger ones, but actually the heaviest total (44.08 pence) is in panels of 2500 to 3000. Moreover in medical lists which are rapidly increasing there is a rising cost

per person; where for instance the practice is grown by one half in the year the average cost for drugs per person is nearly 70 pence. The insured person does not as a rule trouble to secure acceptance or transfer unless he requires treatment. The committee which drew up the report believe that a substantial economy would follow upon a careful investigation of the prescribing of doctors (1) who have qualified since the war; (2) whose medical lists are rapidly increasing; (3) whose practices are mortgaged; (4) whose lists exceed 2000; (5) who practise in the district around Manchester. They would like the panel committee to examine the data from a therapeutical standpoint.

## Appliances at Cost Price

A correspondent in the *Chemist and Druggist* draws attention to what he describes as the custom of a few doctors. Those practitioners who have ordered appliances other than those scheduled, or perhaps foods, on insurance prescription forms, will remember that if the chemist supplies what is ordered he is entitled to be paid and the cost is recovered from the doctor. This particular chemist has noticed that certain doctors are in the habit of ordering expensive appliances, and cheerfully accept the surcharges. He has made inquiries and one doctor gives the following explanation:—

"Let us take a proprietary inhalant as an example. The medicament I order is allowed as a charge on N.H.I. funds, but the cost of the atomiser or inhaling apparatus that the makers recommend is not a proper charge. If my patient wants it he must pay for it himself, and it may cost him 21s. Now, suppose I order it on a prescription form with the liquid medicament. The patient gets the inhaler just the same and they charge it to me, but only at cost price (according to drug tariff rules). The patient in turn pays me for it, and saves, say 5s. on the transaction; the value is deducted from my next cheque, so everybody is satisfied!"

The chemist is not so sure that everyone is satisfied. He has supplied a non-scheduled appliance, and instead of receiving his normal profit on the transaction he has to be content with a mere dispensing fee. But the idea is ingenious.

## OBITUARY

**SIR WILMOT HERRINGHAM, K.C.M.G., C.B.,  
M.D. Oxon., F.R.C.P. Lond.**

THE death occurred on April 23rd of Sir Wilmot Herringham, consulting physician to St. Bartholomew's Hospital, and widely known for his services to medical education and nursing, while his war record was of marked distinction.

Wilmot Parker Herringham was the son of the Rev. W. W. Herringham, of Old Cleeve, Somerset, a prebendary of Wells, by Matilda, daughter of the late Colonel J. B. Parker, commandant, Woolwich. He went to Winchester as a collegier and gaining a classical exhibition at Keble College, Oxford, graduated with classical honours in 1877. A decision to go to the Bar was marked by entrance as a student at Lincoln's Inn, but almost immediately he decided on a medical career and became a student at St. Bartholomew's Hospital. He qualified as M.R.C.S. in 1881 and graduated as M.B. Oxon. in the following year, taking also the diploma of M.R.C.P. Lond. He served as medical registrar at the hospital and was for two years casualty physician, but as was so commonly the case at his school had to wait a period for advancement, not being elected assistant physician to St. Bartholomew's until 1895. He was however elected physician to the West London Hospital and to the Paddington Green Children's Hospital, at both of which institutions he did excellent work. And he had to wait no excessive time at St. Bartholomew's for promotion, as he became full physician in 1904. He lectured for a time on clinical and forensic medicine and published papers on clinical subjects in the transactions of various learned societies and in the columns of the *Journal of Physiology, Brain*, and the *British Medical Journal* and the *St. Bartholomew's Hospital Reports*, but no manual or textbook came from his hand.

Herringham was elected F.R.C.P. Lond. in 1889, and was examiner for the College through two periods. In the course of his educational and hospital work he became deeply interested in the constitution and machinery of the University of London. The controversies involved made bewildering reading at the time, and even when the statutes and regulations made by the Commissioners of the University of London Act (1898) were published few could have followed their meaning, their implications, or their indications for development with any certainty. Herringham was among that small group and displayed in debating the difficulties of organisation a blend of fairness and acumen which led to his election to the vice-chancellorship of the University. This post he held for three years from 1912, and it

was an exceptional compliment to him on the part of the Senate to grant a tenure of office for three years. We have received from one who was admitted to a special degree of intimacy with Herringham during this period the following tribute to his work:

"The two epithets that spring to my mind as specially characteristic of him in that capacity are 'masterful' and 'greathearted' (*μεγαλόψυχος*). To which I may add a third Aristotelian virtue—versatility. These qualities, which were his in an exceptional degree, gave him the ability to control the Senate to their own frank enjoyment and to the speedy transaction of the complicated and frequently controversial business with which they were habitually confronted. Although this body contained a considerable number of experts in various branches of academic attainment, some of whom

moreover were not wholly in agreement with their immediate colleagues, not to speak of inevitable inter-collegiate difference, no one ever appeared to resent Herringham's handling of the situation—all recognised that their corporate choice had fallen upon the right man, and that his essential authority lay not in his office but in himself. His swift and orderly intelligence perceived at once the value and bearing of any suggestion that might however unexpectedly be sprung upon the meeting, both in its immediate application and (what is of wider and more vital consequence) in its relations to the other aspects and interests of the university; and his judgment was never, as far

SIR WILMOT HERRINGHAM

as I can remember, at fault. He had moreover in an especial degree the divine gift of humour, which never deserted him or offended those upon whom it was directed."

In 1913 Herringham had a notable opportunity for displaying similar powers of organisation when he was elected honorary general secretary to the International Medical Congress held in London in 1913 under the presidency of Sir Thomas Barlow. Any who can recall the conduct of the business arising out of that remarkable gathering of the nations will remember Herringham's careful but almost comically informal method of dealing with it. With various assistants round him he saw everyone who needed counsel, attended to all questions with promptitude, always apparently knowing at once to which of his assistants he could look for an exact reply. He could delegate as well as advise. He was precise in any instructions which he gave with regard to the delivery of contributions, and quite stern, even when he appeared to be flippant, with those who defaulted without adequate excuse from supplying promised assistance. The congress, to which notable contributions came from distinguished colleagues in

many lands, was a great success and Herringham received a knighthood which was fully earned.

The following year war broke out and Herringham went to France immediately as consultant physician to the forces overseas. He was already lieutenant-colonel commanding the medical unit of the University of London O.T.C., so that his qualities as physician were supported by complete familiarity with military routine. He did distinguished work as a consultant and it is noted in the "Official History of the War" that with J. W. McNee he reported the first case of relapsing fever where the initial period of pyrexia was shorter and the relapses more frequent and severe. This case led to investigations as to what type of fever was presenting itself, but during the early part of the war none of the exhaustion sequelæ of trench fever were observed, as the many observations were individual, and it was not until 1917 that the Trench Fever Committee was appointed. Herringham was also largely responsible for the sending in to the No. 3 mobile laboratory the notes and specimens which later were represented in a summary of the chief findings in a series of cases of war nephritis, collected by Shaw Dunn and later published in the reports of the Medical Research Committee and the *British Medical Journal*. Herringham recorded his general war experiences in a volume entitled "A Physician in France." This book appealed to a wide circle of readers and brought home to the lay public the important part played by the medical service in an army at war. The book appeared within a year of the cessation of hostilities and supplied information of great public value. He commented on many questions, social, political, and economic, and his criticisms and reflections were throughout relieved by his friendly humour. The work was timely as it defended the Royal Army Medical Corps effectively from much carping detraction which had been put forward by the ill-informed. In noting the advance in medicine during the war, he brought out the romance of scientific investigation as well as the value of organised research, and Herringham's lessons here are equally applicable to the conditions of peace or war. He was appointed C.B. (Military) in 1915, was promoted major-general A.M.S., and received the K.C.M.G. at the close of hostilities.

The nursing profession owes a large debt to Herringham. The General Nursing Council for England and Wales was appointed by the Minister of Health and held its first meeting on May 11th, 1920, and was therefore still in its infancy in February, 1922, when he was asked by the Minister to assume the office of chairman. We owe to Miss E. M. Musson, LL.D., chairman of the Council, this tribute of his work in the chair: "The Council was in 1922 passing through a crisis and it was primarily due to Sir Wilmot's knowledge of committee work and to his determination and prompt action that it became possible to continue. He spent unlimited time probing into every detail of office work and obtained an independent and expert opinion on the organisation with the result that additional staff and more equipment were obtained to cope with the tremendous rush of applications for registration as well as with the work of committees. He not only attended the meetings of council and of all committees, which then met weekly, but spent many hours at the office dealing with the numerous problems inseparable from such a great undertaking. His first concern was to arrange for the election of a new council—the preliminary to which was the formation of the electorate by publication of the first Register in July, 1922. The

first elected council met in February, 1923, Sir Wilmot being unanimously elected chairman, a position to which he was re-elected in 1924 and again in 1925. From the first he maintained that it was due to the dignity of a profession that the chair should be held as soon as possible by a member of that profession and that before the end of the first elected council, elected for five years, the chair should be occupied by a registered nurse. In 1926 he therefore declined nomination, but, at my urgent request, kindly consented to be nominated for the newly created post of vice-chairman, and for the two years during which he remained on the Council he gave me unstinted help and advice whenever I appealed to him. Sir Wilmot's experience in the examination work of a university and the help he was able to obtain for the Council from the University of London were invaluable in the drawing up of the rules and regulations for the conduct of the State examinations and their organisation, as were also his guidance, and that of Sir Jenner Verrall, in legal matters or those where disciplinary situations arose. The financial side of the work always received Sir Wilmot's careful consideration, and he was proud that he left the Council in a sound position in that respect."

At the Royal College of Physicians of London Herringham was a prominent figure. Early appointed an examiner, he became a member of the council in 1908 and served as senior censor. He represented the College on the Senate of the University of London for eight years and was Harveian orator in 1929. His Harveian oration, a fluent delivery without a manuscript, was completely different from all of those exercises. He took it for granted that his audience knew of the researches derived from experiment which had led Harvey to his great discovery, and that the bearings of that discovery on all subsequent medicine must be equally evident to them. He turned to the question of what were the family influences and social environment that accompanied Harvey's work and ministered to its accomplishment, and gave a graphic picture of the family life of the great philosopher. In this oration, an expanded edition of which was published in *THE LANCET* (Nov. 2nd, 1929, p. 911), Herringham displayed his deep and learned interest in late mediæval culture. This was an aspect of history on which he was singularly well informed. He read steadily to the end of his life history, especially French and English, from the time of Harvey until the beginning of the last century, and acquired a store of minute information on the science, art, religious movements, and general politics of the whole period, carrying apparently in his head the reactions of things as they occurred and their influence on the times that followed up till to-day.

Herringham was a member of the University Grants Committee from 1919, the year of the institution of the Committee, until 1932. He took from the first an important part in advising the Committee as to the needs of medical education, and his wide knowledge of the subject enabled him to give real impulse to the movement for the clinical unit system in the London medical schools. He worked in close association with the officiate throughout, and rendered high service from his technical knowledge, contributing also through his warm-hearted personality to the success of the periodical visits paid by the Committee to the university institutions.

Sir Wilmot Herringham married as a young man Christiana, daughter of Mr. T. W. Powell, of Piccard's Rough, Guildford. She was a highly accomplished painter both in tempera and water-colour, a scholar,

and learned in the arts she practised. Their only son was killed in the war, and Lady Herringham was an invalid for several years before her death in 1929. Towards the close of his life he sought consolation and pleasure from his historical studies and the practice of water-colour painting, of which he became an able exponent. An example of his skill appears in the Royal Academy exhibition this year, a drawing of Llanthony Abbey.

Dr. C. M. Wilson writes: "It is, I think, remarkable that in an age of journalism the death of so unusual a man as Herringham should pass almost unrecorded. Successful physicians are common, but good chairmen are rare, and many bodies profited by the fact that his days were not taken up in practice, for Herringham was born to preside over men. It was not a rôle for which he appeared to be cut out. Many would have predicted that he would have been impatient, intolerant, and even aggressive. They would have been very wide of the mark. He believed it was his duty as chairman to sink his own personality. This masterful man with strong opinions on almost everything appeared to have none as he sat there on the bench sifting the evidence. He had always mastered the subject under discussion, and his judgment was seldom at fault; besides he had the chairman's final gift—courage, for he was quite without fear. In the years of his prime it was no doubt this wisdom in council that set him apart from his fellows, and yet strong administrators with vision are common enough. What was unusual was that the man who possessed this gift was a scholar whose life was ruled by a passion for beauty.

"He had an insatiable thirst 'to learn something new and to see something beautiful,' and he had leisure after the war to feed these desires. He went through the countryside whenever he could in a small car—out of which, owing to his rheumatism, he was extracted with difficulty—perhaps to some Oxford or Cambridge college to read an old manuscript play, perhaps to see spring in the fields (for he was a countryman) or an old picture, or some ancient church. He would put some oatcake and a flask of whisky in his haversack along with painting things and start off after breakfast. His painting was not all plain sailing. 'I am doing it very badly. The greens puzzle me and they are not made any better by the continually shifting shadows from the clouds. I love the sunlight on a green hill and all the lines running down the face of it, showing the different slopes, are lovely too.'

"He had mellowed and was content to accept what fate had brought: not that there was much virtue in that, he would add, since it had laid his life in pleasant places under the shadow of old walls—Winchester, Oxford, and St. Bartholomew's, that great school of medicine which for more than forty years had been the centre of his life. It was as natural for him to turn to the past for an explanation of the present as it is to a lawyer to turn to precedents. And in the interpretation of history he sometimes found a key in his knowledge of the arts. He had been looking at some Dutch pictures, scenes of jollity: 'It looks,' he wrote, 'as if Calvinism which was as rabid in Holland as anywhere did not have much effect on popular life.' But when he tried to apply the same test to England, he found nothing but Herrick's *Hesperides*, which was about as foreign to Puritanism as anything could well be. When he was in the 'seventies he taught himself Spanish so that he might read Don Quixote in the original. He spoke French like his own tongue, and could

quote his Dante when it was apt and native to the occasion. But his most intimate friends were the Greeks, whom he read and re-read every day of his life until they were part of him, just as our forbears lived with their Bibles. Herringham did not exist in a land of memories, he lived in the present. Age kept at arm's length from the formidable old man, and it was only a few months before his death that he handed over his fishing tackle to my son. He grew rather lame, a little deaf, but his mind remained supple and his memory was never touched by time. When he was nearly eighty he thought he ought perhaps to retire in favour of a younger man as chairman of Bedford College, but they would not hear of it for the reason that he was so supremely efficient. To the very end Herringham enriched the lives of those who knew him."

#### HENRY JASPER CARDALE, M.B. Edin.

Dr. Henry Cardale, who died at his home in Cubitt Town, on April 22nd, in his sixty-sixth year, was the son of the late Vice-Admiral Charles S. Cardale, and was born at Alverstoke, Hants. He was educated at Kingsley College, Westward Ho! and at Sherborne. He studied medicine at Edinburgh University, winning distinction in many subjects, and graduated in 1895, afterwards holding resident appointments at the Royal Albert Hospital, Devonport, and Fisherton House Asylum, Salisbury. He started in general

practice at Harrow, but in 1902 he moved to the Isle of Dogs and remained there throughout his life. He became an assistant medical officer of the Education Department, and a district medical officer under the L.C.C. hospitals and medical services committee. He was medical officer to a number of societies and insurance companies, police surgeon of the K and Thames Divisions, medical

referee of the Ministry of Pensions, and from time to time acted as a regional medical officer of the Ministry of Health. During the war he was responsible for the medical service of the Inland Water Transport when it was stationed in the dock area, and he rendered service on war pensions under the British Red Cross Society. All this in addition to the grinding toil of a busy private and insurance practice.

The practice which the National Health Insurance Acts brought him Dr. Cardale abundantly repaid by services freely rendered to the administration of medical benefit. He was one of the original members of the London panel committee and became its chairman in 1914, remaining in that office until his death. He was a member of the Insurance Acts Committee, and in 1930 and 1931 was chairman of the annual panel conference. In 1921 he became

DR. CARDALE

(Photograph by Elliott & Fry)

a member of the London insurance committee, serving both on the committee itself and on various of its subcommittees. In March, 1925, he was appointed one of the medical members of the London medical service subcommittee, and his interest in its work may be gauged by the fact that, out of a possible 243 meetings held during the period of his membership, he attended no less than 226. A man of strong opinions, Dr. Cardale was sometimes regarded as intolerant of opposition, but those who knew him best realised that it was an honest conviction of the rightness of his own views which made him seem unappreciative of the viewpoint of others. For this reason he was more effective as a fighter than as a negotiator, although in either capacity he had the happy knack of friendliness. A born raconteur, he could often reduce to helpless laughter his opponents of a few minutes earlier. His passing removes one of the few people who have completely mastered the insurance acts and regulations.

#### THE LATE SIR HAMILTON BALLANCE

WE have received the following tributes to Sir Hamilton Ballance as a surgeon in supplement of the notice published last week. In that notice the statement that Sir Hamilton was originally in general practice was not correct.

Mr. A. J. Blaxland, surgeon to the Norfolk and Norwich Hospital, writes: "Ballance was wholeheartedly devoted to his profession, and even his hobbies of carpentering and deep-sea fishing had an indirect bearing on the perfection of his surgical technique. His enthusiasm for and untiring devotion to his work were a constant source of inspiration and encouragement to his colleagues, and they would all gratefully acknowledge the debt they owe to his example. Those of us who have had the privilege of being his house surgeons and also all his surgical colleagues on the staff of the Norfolk and Norwich Hospital would like to have recorded our deep respect and affection for him as a man, our great admiration for him as a surgeon, and our indebtedness to him for all that we have learnt from him. He was a man of absolute integrity and trustworthiness, and he had a great charm of manner. No one could wish for a better colleague. His chief characteristics as a surgeon were thoroughness and meticulous care, not only in the technique of an operation, but in diagnosis and preparation of a patient and in after-treatment. No time or trouble was too great for him if it were at all likely to add to the comfort or benefit of a patient." Mr. Blaxland adds that not content with being a pioneer in surgery in Norwich he devoted a large proportion of his time to the interests of the profession through official work with the B.M.A. where his high ethical standard proved invaluable.

Dr. A. J. Cleveland, senior physician to the Norfolk and Norwich Hospital, writes: "Ballance came to the hospital at a time when surgical technique was making great advances; the antiseptic method was being supplanted by the aseptic; pathological investigations were becoming a part of clinical surgery; and X rays opened a new field of diagnosis. No man was better equipped for the introduction of the new methods than Ballance, and in conjunction with his colleague Dr. S. H. Long he took up the task with enthusiasm. Extremely painstaking and possessing great powers of application, his work was marked by thoroughness and a conscientious attention to detail. For his clinical judgments he relied

on wide study of surgery and powers of sound deduction rather than on intuition, and these, added to a personality which inspired confidence, soon gave him a high place in his profession. He was unselfishly devoted to the interests of the Norfolk and Norwich Hospital, and all his life took a prominent part in its administration, bringing to the task the same qualities of sound and restrained judgment which marked his surgical work. After close association with him for 30 years it is difficult to express an opinion of the surgeon and the man which is not biased by the affection felt for a friend. But that he deserved the recognition he received and that he was in every way worthy of the position in his profession to which he attained, no one who knew him and his work would question for a moment."

#### THE LATE DR. HAMBLIN SMITH

W. N. E. writes: It was on account of the increasing importance of the medical work at Birmingham prison that it was decided in 1920 to send a medical officer there with special knowledge of mental diseases, and Hamblin Smith was the natural selection for the post. His ripe experience, clinical acumen, and sound judgment were invaluable assets in the daily work of a prison, and enabled him to determine with accuracy the mental states of the trial prisoners under his care. His opinion in the difficult and intricate problems connected with criminal responsibility was relied upon in the courts and by the Prison Commissioners, and his concise and complete reports were models of what a medico-legal report should be. He had not only the prisoners from the Birmingham area but also those sent from outlying prisons for medical observation, and he visited adjacent prisons to confer with their medical officers in capital cases. He was a loyal colleague and in all his work combined charity to the frailties of his patients with jealousy for the reputation of the service. An omnivorous reader of philosophy and speculative psychology, he maintained a clear distinction between assumptions and facts and his theoretical inclinations never obtruded on his daily duties. It was this scientific outlook tempered with common sense that captured and retained the confidence of the courts he worked in.

Dr. WALTER SIRR SHELDON, whose death occurred on April 15th, was educated at St. Paul's School and went for his medical training to University College Hospital where he was junior and senior Fellowes medallist in clinical medicine. He took the English double qualification in 1898 and filled the resident posts of house physician and house surgeon and obstetric assistant. He was also for a time clinical assistant at the Royal London Ophthalmic Hospital. During the war with the rank of temporary captain, R.A.M.C., he served in the Ypres and Etaples centres. He practised in the Bayswater district of London for many years, in succession to his father, the late Dr. Thomas Sheldon.

Dr. HARRY MASON, who died on April 23rd from pneumonia after a short illness, was 59 years of age and had been county medical officer for the North Riding of Yorkshire since 1924. He qualified at Edinburgh in 1900 and, after demonstrating both in anatomy and pathology, began to practise in

## CORRESPONDENCE

## TREATMENT OF PHLEBITIS IN VARICOSE VEINS

To the Editor of THE LANCET

SIR,—The article by Dr. Biegeleisen in your last issue calls for certain comments. Firstly, it contains many statements of fact with which I find myself in complete disagreement; and secondly, the treatment of phlebitis by means of sclerosing injections during the active phase of the disease is diametrically opposed to current teaching in this country.

Dr. Biegeleisen opens by saying: "The conservative treatment of phlebitis in varicose veins has proved unsatisfactory and the purpose of this paper is to present a new method of treating this rebellious disorder, which so often terminates in a permanently damaged extremity." Does clinical experience support this? The statement is also made that phlebitis in varicose veins differs from "ordinary phlebitis" in being subacute or chronic. Actually this so-called ordinary phlebitis is so rare as to provide no real comparison.

After characterising the existing treatment of phlebitis as "confused and timid," Dr. Biegeleisen makes the following statements: "(1) phlebitis in varicose veins rarely heals spontaneously; (2) the danger of embolism is greater in the untreated cases; (3) temporising means permanent lymphatic and tissue damage; and (4) sclerosing injections can safely occlude the dilated infected vessels." My own experience leads me to believe that the so-called phlebitis in varicose veins invariably subsides with conservative treatment, and in many cases does so almost irrespective of the treatment. As regards the danger of emboli, I feel sure an unnecessary bogey has been made of this. Statistics on the point are difficult to obtain but personally I have yet to see a fatal or a non-fatal pulmonary embolus following spontaneous phlebitis in varicose veins. Emboli certainly do occur from time to time, but patients with this complication are rarely seen in the out-patient departments, in the wards, or in the post-mortem room. The argument that conservative treatment of phlebitis leads to permanent lymphatic and tissue damage is only true of the very small group of cases in which the phlebitis really becomes subacute or chronic.

Dr. Biegeleisen states he has carried out immediate sclerosis in a series of 300 cases of phlebitis with good results. As a guide to the infective element in the phlebitis he uses the sedimentation-rate of the blood, and on the basis of his figures divides his cases into four groups, those with active infection and those with probable absence of infection as extremes. This very elaborate investigation is fol-

(Continued from previous page)

Barnsley. Having taken the D.P.H. Leeds he entered the public service as medical inspector of schools in the West Riding, later moving to the North Riding, but never leaving the county of his birth. He was an administrative officer of considerable breadth of view whose devotion to the public welfare made him widely beloved. One of his colleagues writes that his fellow workers found him courteous and kind, always determined to make their way easy for them.

lowed by injection treatment which has to be gauged very carefully to avoid the "flare-ups" which he admits occur after the injection of phlebitic veins. I think, however, the clue to Dr. Biegeleisen's article is to be found in the legend accompanying Fig. 1, which reads: "Phlebitic varicose veins: no tenderness, thrombosis, or hyperthermia. Varicose ulcer present. Sedimentation-rate 20 minutes." If the word phlebitis is capable of being used for a process in which tenderness, thrombosis, and hyperthermia are not present, then it has become too loose in its meaning to have any clinical application. It would appear that he is using the word in a sense other than the accepted one, and that many of his cases are really ones in which old, quiescent, and clinically hard and painless mural thrombi are palpable in varicose veins. Dr. Biegeleisen makes so many statements which are frankly contrary to my own experience, and his use of the word "phlebitis" seems to be so unusual that I must hesitate to accept his arguments in favour of immediate injection treatment in cases of phlebitis. The subject of phlebitis in varicose veins is a thorny one in relation to nomenclature, and the word may be used to cover anything from a thrombosis to a frankly suppurative process. Injection treatment of the type of case he deals with may be safe, but the most acute "flare-ups" I have ever been called to see have followed injection of veins recently the site of phlebitis. In addition to this some at least of the recorded cases of fatal pulmonary emboli have occurred when injections were carried out shortly after an attack of phlebitis.

The conservative treatment of phlebitis is satisfactory in almost all cases of the acute, subacute, and chronic disease. A few cases in all of these groups necessitate surgical treatment, but they are exceptional; the remainder are safely and efficiently dealt with by injections after the phlebitis has subsided. The interval of six months which I observe in these cases is purely arbitrary, but its observance has at least avoided any complications even where the antecedent phlebitis has been of the most acute type.—I am, Sir, yours faithfully,

Harley-street, W., April 25th. REGINALD T. PAYNE.

## VARICOSE VEIN INJECTIONS

To the Editor of THE LANCET

SIR,—I have read with interest Mr. Bennett-Jones's observations in your issue of March 7th (p. 537) on the empty vein technique for the injection treatment of varicose veins. He stresses what I preach in season and out, particularly in "The Cure of Hæmorrhoids and Varicose Veins" (London, 1934). If all injectors would use this method one would not encounter so many of other people's failures. That technique leads to smaller clots, a quicker cure, and less after-pain for the patient. Certainly the tourniquet is to be recommended as a routine measure, but in expert hands, particularly when great numbers have to be dealt with by teamwork at a clinic, there are two quick "dodges" that obviate a tourniquet:

(1) Stand the patient on a stool alongside the operating couch. Place one's left thumb over the vein. Quickly lay the patient on the couch, pierce the vein with the needle, release the thumb, make sure that the needle is in the vein, and inject; or

(2) With the patient standing with a full vein and no

tourniquet, pierce the full vein with a needle. Let it bleed a drop or two, catching the drops on wool. Gently lay the patient down backwards on the couch, affix the syringe to the needle (which is now in an empty vein), draw blood into the syringe (to make sure the needle is still in the vein), and inject.

The tourniquet moreover is unpleasant for nervous patients, especially when pumped up to the arbitrary level of 180 mm. Hg. These "dodges" also save time.

I note that Mr. Bennett-Jones uses exclusively sodium salicylate 30 per cent. Sicard's work was done exclusively with this. But, from long experience with various sclerosing fluids, I have come to the conclusion that different fluids are indicated in different types of veins and also in different types of patients. I largely use lithium salicylate 35 per cent. with 1 per cent. Ethocaine (an injection fluid we owe to R. Maingot), which has all the advantages of sodium salicylate and none of its disadvantages. It has however one drawback that I recently pointed out (*Brit. Med. Jour.*, 1935, ii., 229)—viz., that clots seem to get bigger even ten weeks after an injection and lead occasionally to ulcers many weeks later. Therefore I avoid this fluid in superficially placed or thin-walled veins. Quinine is, I think, the most constant fluid to be effective; but patients do not like its associated momentary flushing of the face, buzzing head, and palpitation. Sodium morrhuate is most useful for small superficial veins, and its froth for skin venules. But it has its dangers in susceptible people (see *Brit. Med. Jour.*, 1933, i., 430, 674).

I would commend to Mr. Bennett-Jones the value of firm pressure over a large strip of the vein, for three days subsequent to its injection, of a firm wad of wool held in position by Elastoplast. In this way one secures smaller clots, a greater likelihood of occlusion, and, I am convinced, less chance of ultimate recanalisation.

I am, Sir, yours faithfully,

Liverpool, April 21st.

STUART MCAUSLAND.

## GASTRIC ACIDITY AND ITS SIGNIFICANCE

*To the Editor of THE LANCET*

SIR,—In an article under this title in your issue of Jan. 4th Prof. F. L. Apperly states that it was he who with Crabtree showed in 1931 that the  $\text{CO}_2$  content of the fasting blood plasma governed the acidity of the gastric contents after a test-meal in any one individual, and that the  $\text{CO}_2$  content of the plasma was responsible for the differences in gastric acidity existing between different individuals. I wish to call attention to the fact that this observation was made and described first by me (*Klin. Woch.*, 1924, iii., 1951), and that I subsequently enlarged on this subject in several other publications (*A New Approach to Dietetic Therapy, Metabolism of Water and Minerals and Its Disturbances*, Boston, 1933, &c.). I showed, in addition, that in reality it is the concentration of all the acid substances in the blood rather than that of  $\text{CO}_2$  alone that, in accordance with the rules of physicochemistry, influences the concentration of hydrochloric acid in the gastric cavity. The acid substance of the blood which is quantitatively most important is  $\text{CO}_2$ , and since the variations in the concentration of this acid are the most common occurrences, in most (but not all) cases a parallel behaviour might be found between its concentration in the blood and the gastric acidity.

In addition to the concentration of the acid substances in the blood I showed that there is another factor that influences the concentration of hydrochloric acid in the gastric cavity. This is the permeability of the membrane formed by those cells of the mucosa of the fundus of the stomach in which the production of hydrochloric acid takes place. If the permeability of this membrane decreases, as may occur as a consequence of a chronic gastritis, a low hydrochloric acid concentration or, in other words, a hypochlorhydria or achlorhydria may be found, notwithstanding the presence of a high  $\text{CO}_2$  concentration in the blood or, generally speaking, in spite of a "hyperacidemia." (This relationship is similar to the association of a high urea-nitrogen content in the blood with a low urea-nitrogen content in the urine as a consequence of decreased permeability of kidney cells in chronic glomerulonephritis.) The existence of a chronic gastritis and the consecutive decrease in the permeability of the gastric mucosa would explain the seeming contradiction (to which Dr. Hurst calls attention in your issue of Jan. 18th, p. 168) that notwithstanding there is a high  $\text{CO}_2$  content of the blood the hyperchlorhydria postulated by Apperly is absent in bronchial asthma.

Another statement made by Apperly is that "there is a direct relationship between the red cell content of the blood and gastric acidity." This observation also was first published by me in the year 1924 (*Zeits. f. d. ges. exper. Med.*, 1924, xli., 342, &c.). I described my findings in a statement that the higher the percentual volume of the red blood-cells in the whole blood ("hematocrit value") the higher the gastric acidity. The existence of this relationship was explained by the observation that both the hematocrit figure and the gastric acidity are governed by the concentration of the acid substances in the blood. Mention should be made, however, that the behaviour of the red blood-cells is identical with that of acid substances in the blood, so that not only are these former influenced by the concentration of the latter, but that the red blood-cells in their turn influence the concentration of the acid substances in the blood, hence influence the gastric acidity as well. Consequently, a hypochlorhydria or achlorhydria may follow if there is a decrease in the red blood-cell content of the blood, an occurrence which I described in 1924 as "hematogenous hypochlorhydria or achlorhydria" (*ibid.*, 1924, xliii., 247) and to which Apperly's anæmic achlorhydria corresponds.

It would appear, therefore, that Hurst goes too far in his contention that the red blood-cells do not influence the gastric acidity. In the production of the hydrochloric acid concentration in the stomach, however, consideration must not be given to the presence and physiological significance of only one acid substance, such as the erythrocytes, but to the concentration of all the acid substances. Thus the acids of the blood represented by the red blood-cells may be decreased on account of anæmia and yet the sum total of all the acids may be normal or higher than normal. This would explain the observation that anæmia may exist without achlorhydria or with normal hydrochloric acid concentration or even with hyperchlorhydria, the existence of such cases contradicting, as pointed out by Hurst, the assertion of Apperly that, when the red blood-cell content of the blood falls to about one-half or two-thirds normal, free acid disappears from the stomach.

I am, Sir, yours faithfully,

New York City, March 14th.

EUGENE FÖLDES.

### PROPHYLACTIC ENUCLEATION OF LOWER WISDOM TOOTH FOLLICLES

To the Editor of THE LANCET

SIR,—I am sure that the medical profession as a whole will be grateful to Mr. Bowdler Henry for bringing forward such an easy and entirely satisfactory procedure to cope with what is often a menace—namely, a badly impacted unerupted lower molar tooth. By such a prophylactic measure as Mr. Henry has introduced, all the numerous risks which are attendant upon maleruption are eliminated. Surgeons are familiar with some of the complications which follow the extraction of a badly unerupted third molar and it has been my lot to be called into consultation several times when fracture of the jaw has resulted from attempts to remove such a tooth. I can vouch that prophylactic enucleation is entirely free from trauma, and is quite a simple operation; one only wonders why such an easy remedy had not been thought of years ago.

I am, Sir, yours faithfully,

CECIL P. G. WAKELEY.

Queen Anne-street, W., April 22nd.

### PURPURA HÆMORRHAGICA FOLLOWING MEASLES

To the Editor of THE LANCET

SIR,—Your last issue contained an account of purpura complicating scarlet fever, and it may be of interest to put on record a case in which it followed measles.

A girl, aged 4, was admitted to this hospital on April 8th, with the provisional diagnosis of "black measles." It appeared that she had a measles rash on March 29th; on April 7th she came out with a hæmorrhagic rash and passed blood in the fæces and urine. She had widespread petechial and purpuric hæmorrhages all over the body and sordes of coagulated blood. The hands were a deep dark blue, the face pale and the child obviously poorly. Temp.,

99° F.; pulse-rate, 120. She was given 20 c.cm. of whole blood from her father, as well as glucose and saline intramuscularly. Both punctures bled very freely, but curiously when 20 c.cm. of scarlatinal antitoxin was given, also intramuscularly, the puncture did not bleed. She passed a dark tarry stool; the urine was bright red with blood. Blood-platelets numbered 35,000 per c.mm.; otherwise there was nothing strikingly abnormal in the blood. Prof. J. F. Wilkinson was consulted and advised intensive vitamin-C therapy, both oral and hypodermic; ascorbic acid was used, and in addition eight lemons were given daily. She continued to pass blood until April 15th, when both fæces and urine were clear. The skin gradually cleared, but peeled profusely and serum continued to ooze in places. She is making good progress towards complete recovery. On April 24th the blood-platelets were up to 100,000 per c.mm., and the general condition has improved considerably.

I am, Sir, yours faithfully,

W. EDGE,

Medical Superintendent, Ladywell Sanatorium and Isolation Hospital, Salford.

April 27th.

### OMNIPRATICIENS

To the Editor of THE LANCET

SIR,—I have just observed that in a circular emanating from the publishers of a medical book in Paris they state that "Tous les médecins (omnipraticiens et spécialistes) doivent avoir ce petit volume sur leur bureau." The word "omnipraticiens" is new to me, and I suppose is nearer akin to the English "general practitioner" than was the old expression "médecin praticien." I have no knowledge of how far the new word is generally used in France, but it is certainly compact if it means "general practitioner" as in English, and it may be quite useful to our own doctors visiting France if they wish to describe their position concisely in modern language.—I am, Sir, yours faithfully,

London, April 24th.

BLANCUS.

## PUBLIC HEALTH

### Revised Milk Designations

THE Milk (Special Designations) Order, 1936, was made available last Saturday and will come into force on June 1st. It supersedes the two draft orders which have been issued and lays down the new system of milk grading.

The grades at present in force are :—

Certified  
Grade A (tuberculin tested)  
Grade A  
(Grade A (pasteurised))  
Pasteurised.

There is no necessity for producers to conform to the standards established for these grades, and most milk sold to the public is undesignated. The new regulations make no change in this policy: they do not require that all milk shall be graded. Instead they continue the plan by which designations are given as a mark of commendation for efforts to reach a better standard.

The new scheme is simpler than the old, and essentially there are only three grades :—

Tuberculin-tested  
Accredited  
Pasteurised.

Additional descriptions may, however, be added by

producers who are suitably qualified. If tuberculin-tested milk has been bottled on the farm—like the present Certified milk—it may be described as tuberculin-tested (certified); if it has been pasteurised it will be called tuberculin-tested (pasteurised). Furthermore accredited milk may be described as "farm bottled." Hence the varieties available to the public (not necessarily in order of merit) will be—

Tuberculin-tested (certified)  
Tuberculin-tested (pasteurised)  
Tuberculin-tested  
Accredited (farm bottled)  
Accredited  
Pasteurised

and, of course, undesignated milk.

It will be observed that all tuberculin-tested milk will now be described as such—whether or not the term "certified" is applied in addition. The old requirements were that certified milk should contain not more than 30,000 bacteria per c.cm. and Grade A (T.T.) not more than 200,000; and until the end of this year the latter standard will hold good for the new T.T. grade. After that time the bacterial plate-count will be discontinued in favour of a methylene-blue reduction test (see THE LANCET, April 11th, p. 866). In addition, no coliform bacilli should be found in 0.01 millilitre—a requirement similar to that for Grade A (T.T.). Tuberculin-

tested milk (pasteurised) must contain less than 30,000 organisms per millilitre.

Accredited milk corresponds closely with the present Grade A. To qualify under the Milk Marketing Board's scheme, the accredited herds, like the Grade A herds, undergo routine examination by veterinary surgeons every three months, and the milk they yield will have to pass the same methylene-blue test as the T.T. milk. The cows, however, are not tested with tuberculin.

The regulations governing pasteurised milk are not substantially altered from those of 13 years ago, except that temperature records must be made and kept for not less than a month. It must contain fewer than 100,000 organisms per millilitre at any time before delivery to the consumer. The licensing authority for pasteurising establishments is, as before, the local sanitary authority (i.e., the council of a borough—including a metropolitan borough—or of an urban or rural district). But licences to producers of tuberculin-tested milk will in future be granted by the councils of counties and county boroughs and not directly by the Ministry of Health.

### INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED  
APRIL 18TH, 1936

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1858; diphtheria, 892; enteric fever, 29; pneumonia (primary or influenzal), 897; puerperal fever, 27; puerperal pyrexia, 103; cerebro-spinal fever, 25; acute poliomyelitis, 2; acute polio-encephalitis, 1; encephalitis lethargica, 5; dysentery, 45; ophthalmia neonatorum, 93. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 24th was 6528, which included: Scarlet fever, 972; diphtheria, 904; measles, 3335; whooping-cough, 560; puerperal fever, 10 mothers (plus 6 babies); encephalitis lethargica, 282; poliomyelitis, 5. At St. Margaret's Hospital there were 24 babies (plus 10 mothers) with ophthalmia neonatorum.

*Deaths.*—In 122 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 102 (46) from measles, 6 (2) from scarlet fever, 42 (11) from whooping-cough, 26 (6) from diphtheria, 51 (26) from diarrhoea and enteritis under two years, and 52 (5) from influenza. The figures in parentheses are those for London itself.

Measles remains the most fatal infectious malady of the period, the number of deaths for the last eight weeks working backwards being 102, 103, 81, 104, 114, 105, 84, 88 for the country as a whole, and 68, 60, 43, 62, 62, 58, 47, 38 for Greater London. Birmingham reported 4 deaths, Barking, Leyton, Southampton, Bradford, Liverpool, and Manchester each 3, no other great town more than 2. Birmingham also reported 4 deaths from whooping-cough, Liverpool, Manchester, and Wigan each 3. Deaths from diphtheria were reported from 16 great towns, no more than 2 from any one of them.

The number of stillbirths notified during the week was 291 (corresponding to a rate of 44 per 1000 total births), including 41 in London.

**A Festschrift for Dr. Lambotte.**—In recognition of his contributions to surgery, the friends, pupils, and patients of Dr. Albin Lambotte, of Antwerp, have decided to publish a jubilee book in his honour. The value of his work in bone surgery particularly in the open reduction of fractures and their fixation by metal prostheses, has had world-wide acknowledgment, and it is fitting that the book also should be international in its scope. Among the more than fifty contributors will be Albee, Fairbank, Hey-Groves, Leriche, Putti, Sauerbruch, Smith-Petersen, and Steindler. The work will be devoted to the surgery of bones and joints, and particulars may be had from Dr. Jean Verbrugge, 75, Avenue Van Ryswyck Antwerp, Belgium.

## THE SERVICES

### ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. T. J. O'Riordan to *Royal Sovereign*; L. F. Strugnell to *Pembroke* for R.N.B.; H. H. Babington to *President* for R.N. Recruiting Headquarters; and E. L. Markham, O.B.E., to *Pembroke* for R.N.B.

Surg. Lt.-Comdrs. S. J. Savage to *Drake* for R.N. Hosp., Plymouth; and D. C. Drake to *Guardian*.

Surg. Lt.-Comdrs. (D) A. A. Gardner to *Greenwich*; H. A. Ginn to *Valiant*; and A. W. Wallace to *Maine*.

Surg. Lts. A. F. Ferguson and H. P. L. Rhodes to *Drake* for R.N.B.; D. N. Williamson to *Victory* for R.N.B.; and J. B. Morris to *Pembroke* for R.N.B.

Surg. Lts. (D) A. W. Y. Price to *Pembroke* for R.M. Infirmary, Deal; and W. C. G. Ford to *Malabar* for R.N. Hosp., Bermuda.

### ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lts. J. E. L. Morris to *Ramillies*; and F. J. S. Gower (proby.) to *Curacao*.

Surg. Sub-Lt. R. T. Gaunt to be Surg. Lt.

Surg. Sub-Lts. J. Scott to *Pembroke* for R.N. Hosp., Chatham; P. de B. Turtle to *Vernon*; and R. T. May to *Royal Sovereign*.

### ROYAL ARMY MEDICAL CORPS

Lt.-Col. W. H. S. Burney, having attained the age for retirement, is placed on ret. pay.

Maj. R. E. Barnsley, M.C., to be Lt.-Col.

Short Service Commissions: Lts. G. S. Musgrove and N. I. McLeod to be Capt.

Maj. B. H. C. Lea-Wilson is secd. for serv. under the Foreign Office.

### REGULAR ARMY RESERVE OF OFFICERS

Maj. J. W. Houston, D.S.O., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

### ARMY DENTAL CORPS

Short Service Commissions: the undermentioned to be Lts. (on prob.): D. V. Taylor, D. S. Wilson, and R. Walker.

### TERRITORIAL ARMY

Capt. J. R. Robertson is restd. to the Estab.

Lts. A. Cowie and C. K. D. Edwards to be Capt.

Supernumerary for service with O.T.C.: S. M. Whitteridge (late Cadet, Univ. Coll. Sch. Contgt., Jun. Div., O.T.C.) to be Lt. for duty with the Univ. of Lond. Contgt. (Med. Unit), Sen. Div., O.T.C.

### TERRITORIAL ARMY RESERVE OF OFFICERS

Capt. R. M. Allardyce, from Active List, to be Capt.

### ROYAL AIR FORCE

Flight Lts. G. W. McAleer to Medical Training Depôt, Halton; C. G. Harold to Central Medical Establishment, London.

Flying Officer F. W. Whitehead to Medical Training Depôt, Halton, on appointment to a short service commission.

W. J. Fowler is granted a short service commission as Flying Officer with effect from Dec. 2nd, 1935.

Flight Lt. R. G. Freeman is promoted to the rank of Squadron Leader.

### INDIAN MEDICAL SERVICE

Majs. to be Lt.-Cols.: A. C. Craighead, P. H. S. Smith, and H. J. H. Symons.

Cpts. to be Majs.: M. K. Afridi and G. S. Chawla.

Lt. (on prob.) E. H. Wallace is seconded while holding an appt. at the Cumberland Infirmary, Carlisle.

Capt. V. A. Edge retires.

**ELIZABETH GARRETT ANDERSON HOSPITAL, LONDON.** The accounts for last year show an excess of income over expenditure of £385, and during the past year 2264 patients were admitted. An appeal was made in 1935 for £50,000 for the new nurses' home and private patients' wing.

## PARLIAMENTARY INTELLIGENCE

### NOTES ON CURRENT TOPICS

#### The Budget and the Social Services

ON April 22nd the House of Commons went into committee of ways and means on the Budget resolutions.

Mr. PETHICK-LAWRENCE said he doubted whether in peace time any Budget statement so staggering in its future outlook had ever been presented in that House. Was there no prospect that the resources of the nation were to be utilised for the development of the country as a whole? Were they to see an enlightened change in the treatment of the unemployed, and the abandonment of the cruel and indefensible means test? No. The policy of the Chancellor of the Exchequer squandered national prosperity by increasing armaments. The Labour Party, quite as much as their opponents, believed in the defence of the country, but they believed that defence depended on foreign policy.

Sir ARCHIBALD SINCLAIR said that the Liberal Party did not deny the necessity for adequate provision for defence against foreign aggression, but they said that defence problems must be considered as a whole. They urged that the Government should work for peace and economic co-operation between all countries with as much will and energy as they were throwing into their policy of rearmament.

Mr. MINTO RUSSELL said the rearmament programme was an insurance premium which had got to be paid; there were other fields in which the national expenditure could be drastically cut down. He suggested the setting up again of a committee on the lines of the May Committee to investigate how this could be done. He asked the Chancellor to consider the advisability of broadening the basis of direct taxation. There were at the last election some 31,000,000 electors, and only 3,000,000 direct taxpayers. He saw the gravest danger of certain sections of the electorate voting to themselves, either consciously or subconsciously, benefits and amenities at the expense of other sections. To lower the basis of direct taxation would help to bring into clearer relief the correlation between cause and effect. Unless there was some greater control over finance, the country would find itself again going down the slippery slope.

Mr. BENSON said that in spite of the tremendous growth of the wealth of the country, there was the shameful fact that 50 per cent. of the population still showed signs of malnutrition. In this Budget the Chancellor had thrown a still greater burden on the indirect taxpayer, who was primarily the small man. Of the proposed increase of £64,000,000 in expenditure, a bare £3,000,000 was allocated for the distressed areas. Apparently he did not anticipate any more social legislation for the next 12 months. He had made no allowance for the new scales of unemployment benefit.

Mr. M. BEAUMONT said that they could not redistribute wealth through high taxation and social services and through increased wages at the same time. He believed that the latter was the sounder way. They would be foolish if they believed that this increased expenditure on armaments was temporary. The country was now able to carry the burden because it was on the upward grade of a trade cycle. But they were approaching the point where they would not be able to find new sources of revenue with which to meet the national liabilities.

Mr. DAVID ADAMS urged special treatment for the distressed areas. There ought to be specific grants made for each of the social services in order to equalise to some extent the huge disparity in rating burdens.

Mr. R. J. TAYLOR regretted no mention in the Budget speech of the problem of maternal mortality. Those who were going into the Army wanted something to fight for, not surtax payers, but decent comfortable homes.

Sir ISIDORE SALMON said that he did not think a better method could be found of giving the people something in their homes than by finding work for them.

Mr. DALTON suggested that the Chancellor should consider next year whether the surtax limit should not be brought down from £2000 a year to £1500 a year. By that means he estimated they would bring in at least 40,000 more contributors, and bring under taxation at least £70,000,000 more of income each year.

Mr. W. S. MORRISON, Financial Secretary to the Treasury, replying to the debate, claimed that the securing in time of danger of adequate defences for the nation was a true work of national importance which every citizen had an absolute right to see carried out. All other expedients for using the public credit for various purposes of a sectional or local character, important and valuable as those works might be, faded into insignificance when compared with the primary task of seeing that the country had adequate defences which would enable it to play its full part in a policy of collective security and would put us in the last resort in a position, not to be a menace to our neighbours, but, if the idea of force prevailed in the world, to render it a more difficult and dangerous enterprise for anyone to attack us.

#### THE DEBATE RESUMED

ON April 23rd Mr. MCGOVERN said that during the financial crisis of 1931 large numbers of people were involved in considerable suffering and sacrifice. They were led to believe that those sacrifices were temporary, and that when prosperity returned the Government would make good the losses which the people were being asked to bear. As a result of this so-called crisis social reform seemed to have been relegated to the background, and since 1931 no first-class measure of social reform had been passed in this country. Changes were made by the Act of 1932 that took away the right to maternity benefit from a large number of wives of unemployed men and also took away medical rights. Surely they ought now to annul those extreme measures and give these people the security to which they were entitled.

Mr. CHURCHILL recalled that the Chancellor had referred with pride to the increasing growth of our social services. He shared in that feeling. The social services must not be considered as a weakening of the strength of the nation. He believed that those services had given us that foundation which was essential to national unity and without which it would be hopeless for us to attempt to make headway against the many perils which were moving towards us.

Mr. MORGAN JONES said that the distressed areas had been described as a creeping desert. The people in those areas were as much entitled as any other section of the community to generous consideration.

Mr. ELLIS SMITH said that unless the Government dealt with the means test very soon it would be faced with a similar position to that with which it was faced not very long ago. Throughout the country, particularly in the North, men were being driven to suicide, and domestic friction was being created unnecessarily. He asked for a drastic change in the administration of the means test and the early introduction of new unemployment regulations.

Mr. LYONS said that our social services—the greatest ever known—had continued unimpaired. Something had been said in the debate about the omission of the Budget to deal with maternal mortality, but in a few days the House would consider

a Bill providing, for the first time in this country, for a national system of paid nursing services to expectant mothers. It was no use saying that maternal mortality, deplorable as the figures were, was one of those things which could be related to unemployment. Nobody would deny that unemployment, malnutrition, and bad nursing were factors which had to be provided for, and which he hoped would be provided for when a full account was taken. But they were not all. Whatever might be our duty to the country and to collective security, there was to be no reduction in the social services and no halting in their progress.

Sir ARNOLD WILSON suggested that it was within the power of the Government to get better value for what they were spending. He found from the report of the Charity Commissioners for 1934 that there were 244 charities for blind persons. There were only 63,000 blind persons in England; one society for every 250 persons. That was a waste of money. As many charities were entitled to a rebate of income-tax the Chancellor might reasonably inquire from the Commissioners a certificate that they were efficiently organised, and that there was no overlapping. They would have to get back before long to the minority report which advocated the breaking up of the 6000 independent units of friendly societies and the reconstitution of them on a basis of county and county borough, making the cost of administration far less.

Mr. ARTHUR GREENWOOD said that this was a war budget with no consideration for the social services. The scale on which rearmament had been envisaged by the Government would necessitate an expenditure so large that it could only be met by increased taxation of the rich or by further impoverishing the poor and putting posterity in pawn.

Mr. CHAMBERLAIN, replying to the debate, said this was a Defence budget. He had deliberately put on fresh taxation because he believed that the people of this country ought to feel that they had to pay for the necessities of the situation.

#### Paying Patients in Voluntary Hospitals

On April 28th Standing Committee B of the House of Commons considered the Voluntary Hospitals (Paying Patients) Bill.

Clause 1, which defines the meaning of the terms "voluntary hospital," "committee of management," and "Order," was agreed to.

Clause 2 provides for accommodation for and charges to paying patients, and subsection (4) enacts that the Charity Commissioners may, from time to time on the application of the committee of management, vary or revoke an Order authorising the provision of such accommodation and treatment if in their opinion there has been any material change in the circumstances existing when the Order was made.

Mr. R. J. DAVIES moved an amendment to provide that the Order might be varied or revoked if for any other reason the Charity Commissioners thought it was expedient. He said that the object of the Bill was the very simple one of removing the legal obstacles that now stood in the way of providing private accommodation in hospitals for persons requiring surgical or other treatment and were able and willing to pay for such treatment. So far, they agreed to the full with that proposal. They had a feeling, however, that in the case of persons who could afford to pay they might, by the Bill, take up accommodation for what might be called members of the middle-class community, and that by doing that—although with the very best intentions and it was necessary it should be done—they might preclude the provision of accommodation for those who required the same treatment, but could not afford to pay at all. The amendment sought to give power to the Charity Commissioners so to vary the Orders that the point he raised would be met. If

the promoters of the Bill would accept the idea propounded in the amendment and put down words on the Report stage to meet the case, he would not unduly press the amendment.

Mr. STOREY said that the amendment was based on a misconception. He differed from Mr. Davies in the view that under the Bill accommodation which should be free might be taken up. His experience of hospitals was that the provision of accommodation for paying patients freed the ordinary beds. In a hospital with which he had been very closely connected for many years, they took into the ordinary wards patients who could afford to pay. They provided accommodation for paying patients and thereby freed beds in the ordinary wards because the paying patients went into the paying wards. Clause 4 of the Bill contained a general overriding provision that an Order should not be made if it would result in less accommodation being available. As Clause 2 was now drawn, any material change of circumstances would enable the Charity Commissioners to revoke or vary the Order. That would apply, for instance, if a hospital suddenly had more funds that would enable it to treat ordinary patients, or any other circumstance of that sort.

The point which really weighed with him was that if they were to go out and collect money for paying patients' wards, they must be able to give some security to the persons who provided the money. They would have difficulty in collecting money for such wards if they had to tell the subscribers that the Charity Commissioners could come along and, for any other reason unspecified, change the whole purpose of the trust for which the money was being given. If there were an unexpected demand for ordinary beds, and if a hospital had the ability to finance ordinary beds, that would be a material change of circumstances which would enable the Charity Commissioners to step in; but they ought not to be left with power for any other reason unspecified to vary a trust which had been created for a specific purpose. These Orders would be made for a period, and it would then be possible for them to reconsider the Order if there had been any material change in the circumstances.

Mr. DAVIES said he would withdraw the amendment and consider what should be done on the Report stage.

Mr. STOREY said he would be willing to discuss the matter before the Report stage and if they could agree on some form of words which would give the security required he would be very glad.

Mr. W. A. ROBINSON asked if there was any possibility of the Bill cutting across any existing schemes such as the penny in the £ scheme.

Sir ALAN ANDERSON, as one who had had a great deal to do with the finances of hospitals in London since the war, said that so far from the existence of pay-beds reducing the number of beds available for persons who could not pay, it had had exactly the opposite effect. The movement for paying wards was a very great advance in the facilities available for those persons who could not afford to pay.

Mr. FRANK ANDERSON asked if there was anything in the Bill which would safeguard the position of paying patients with regard to doctors' fees. He wanted to be assured that if patients came into this category they would not be subjected automatically to an increase in the doctors' fees. He had a case in mind, which occurred not long ago, where a patient went into a certain institution not far from Manchester. The doctor, in the first place, said that the fee would be two guineas, but when it was found that the person in question was possibly able to pay more, the doctor immediately increased the fee to three guineas.

Sir DONALD SOMERVELL, Attorney-General, said that the Bill was designed solely to provide a convenient procedure whereby certain hospitals could get over legal obstacles which now prevented them

from establishing beds for paying patients. Those hospitals, and there were many of them, which could start paying beds by the terms of the trusts under which they operated, without having to come to Parliament for a private Act, or to take any step of that kind, would be quite unaffected. The Bill was merely designed to provide a convenient procedure in the case of those hospitals which, by reason of a private Act of Parliament, or their original trusts, were not able, without parliamentary sanction, to undertake such a scheme. There was general agreement in the Committee that this was a desirable object. Penny in the £ schemes, or twopenny contribution schemes, which were so valuable an aid to hospital finance, were outside the Bill altogether and had nothing to do with it. The point raised by Mr. Anderson, as to the actual arrangements which particular hospitals might make as to doctors' fees, was also outside the Bill. They could operate with or without the Bill. The whole question of what charges should be made and what charges were proper, was one which affected all the hospitals of the country, and all that the Bill did was to say that those hospitals which could not proceed at present under their own powers, and would have to come to Parliament for a Private Bill could go to the Charity Commissioners and get an Order. It was quite true that that Order would, as part of its terms, deal with the general charges that should be made, and would no doubt follow what seemed to the Charity Commissioners—he thought they could be trusted in this matter—to be a proper and reasonable scale to apply to any scheme they might draw up.

Mr. STOREY, replying to points raised by other members, said that the Bill would ensure that the provision for pay beds would be met out of monies given for the purpose, and that existing funds available under the original trusts would not be used, except in circumstances that would cause no loss of facilities for ordinary patients. Land must not be used unless it would not in any case be used for ordinary beds; existing buildings would not be used unless it was not possible to use them for ordinary patients, or they were not required for ordinary patients owing to lack of demand: or unless the hospital authorities provided additional buildings in exchange. If he thought that the Bill would harm the Penny in the £ scheme he would oppose it. The question of doctors' fees for services from the resident staff was covered in the Bill. If special treatment was required that would be a matter for arrangement between the patient and the doctor concerned.

Mr. ANDERSON said that if a patient had entered an institution and it was found that possibly he could afford to pay more, he should have the right to know whether or not a proper charge was being made on him in accordance with the Order.

Mr. STOREY said that there would be a definite scale of charges laid down for the whole treatment rendered by a hospital and its resident staff. That scale of charges could not cover specialist fees for professional services rendered by visiting surgeons or physicians.

The amendment was withdrawn and the clause was agreed to.

[The remaining clauses were agreed to, and the Bill was ordered to be reported, without amendment, to the House.]

In the House of Commons on Wednesday, April 22nd, Mr. CLEMENT DAVIES presented the Buckingham Charity in Dunstable Bill, a measure "to confirm a scheme of the Charity Commissioners for the application or management of the Charity of Arthur Frederick Buckingham for a cottage hospital in the borough of Dunstable in the county of Bedford." The Bill was read a first time.

On Monday, April 27th, the Bill was read a second time.

## HOUSE OF COMMONS

WEDNESDAY, APRIL 22ND

### Medical Facilities in Palestine

Captain STRICKLAND asked the Secretary of State for the Colonies whether he was aware of the complaints as to the existing dangerous condition of the road between Jaffa and Haifa, and that on many occasions large communities were completely isolated, unable to market their produce or even secure medical assistance during one-third of the year; and if he was yet in a position to state to what extent the construction of the road between these two places was to be accelerated during the current year.—Mr. THOMAS replied: I am aware that complaints have been made. The expenditure of £25,000 on the construction of the road during the current year has already been approved, and I hope that, if the financial position permits, it will be possible to make increased provision later in the year.

### Poison Gas and Food Contamination

Mr. WILSON asked the Minister for the Coördination of Defence what steps had been or were being taken in Sheffield for the prevention of the contamination of food-supplies in the event of an air attack in which poison gas was used.—Sir T. INSKIP replied: I am not aware of any particular steps which have been or are being taken in Sheffield, but I am informed that the Home Office is preparing for general guidance a memorandum on the protection of food-supplies against gas contamination. When this is published local authorities will be asked to take whatever precautions seem desirable, acting in collaboration with local merchants and purveyors of foodstuffs.

### Death of Child at a Children's Home

Mr. LOVAT-FRASER asked the Minister of Health if his attention had been called to the death of a boy of six years of age at the Burnham-on-Sea Children's Home on Feb. 9th, in respect of which a jury returned a verdict that the cause of death was shock caused by intense cold in a case of malnutrition of body and multiple minor injuries; and if he would ascertain and inform the House what were the multiple minor injuries from which the child was suffering.—Sir KINGSLEY WOOD replied: I am aware of this case which has received careful consideration and has been fully investigated by a special committee appointed by the county council as a result of which the appointment of the matron of the home has been terminated.

MONDAY, APRIL 27TH

### Accredited Milk Producers' Scheme

Sir PERCY HURD asked the Minister of Agriculture how many milk producers had entered the accredited milk producers' scheme and the amount of their gallonage in relation to the total milk sales in England and Wales.—Mr. ELLIOT replied: The number of accredited producers as at April 1st, 1936, was 15,762. The number who were on the roll during March was 15,350, and sales by these producers in that month under the Milk Marketing Scheme amounted approximately to 24½ million gallons, equal to nearly 30 per cent. of the total sales under the scheme during that month.

### Cleanliness of Imported Butter

Mr. LAMBERT asked the Minister of Health if he had information as to the condition of the cows in the Soviet Union, Finland, Estonia, Latvia, and Lithuania from which countries butter was exported to Great Britain; and if he was satisfied as to the cleanliness of the methods employed in making such butter.—Mr. SHAKESPEARE, Parliamentary Secretary to the Ministry of Health, replied: No, Sir, but my right hon. friend is advised that practically all milk and cream used in the preparation of imported butter is pasteurised.

TUESDAY, APRIL 28TH

### Overcrowding in Scotland

Mr. MAXTON asked the Secretary of State for Scotland how many reports as to the state of overcrowding had

now been received, what percentage that number was of the total, and what was the percentage of overcrowded houses as revealed by the reports.—Sir GODFREY COLLINS replied: Reports have been received from 216 local authorities, representing 94.7 per cent. of the total number of local authorities in Scotland. The percentage of overcrowding in surveyed houses as revealed by these reports is 23.5 per cent.

#### National Health Insurance and Dental Benefit

Sir ARNOLD WILSON asked the Minister of Health (1) how many men and women, approximately, were entitled to dental benefit at the rate of 50 per cent., more than 50 per cent., less than 100 per cent., and 100 per cent. of the cost of treatment, respectively; and how many men and women so entitled in each category actually received treatment during 1934; (2) whether he was aware that the amount spent on dental benefit under the National Health Insurance Acts had fallen steadily from £2,425,000 in 1930 to £1,791,000 in 1934, whereas the sum of £2,437,000 was available in that year for dental benefit; and whether, in view of the need for an extension of dental benefit to all insured persons, he would initiate special inquiry into the position; and (3) whether he was aware that, out of an insured population of 12,000,000 men and 6,000,000 women, only 9,000,000 men and 2,000,000 women were at present entitled to dental benefit,

and of the 11,000,000 persons thus eligible only 700,000 received treatment of any kind during 1934; and whether, in view of this evidence that the dental benefit scheme was not meeting the needs of insured persons, he would initiate a special inquiry into the position.—Sir KINGSLEY WOOD replied: The figures given by my hon. friend are approximately correct. As he is aware, however, dental benefit can be provided under the National Health Insurance Act only by an approved society which has a disposable surplus on valuation and which elects to include it in its scheme of additional benefits. It is estimated that about two-thirds of the insured persons entitled to dental benefit are covered by schemes which provide for the payment of 50 per cent. of the cost of treatment. The proportion of the total entitled to receive the full cost of dental treatment is very small. No particulars are available as to the numbers of men and women in the various categories referred to, and to obtain this information it would be necessary to ask for a return from each of the 5000 societies and branches which provide the benefit. The Royal Commission on National Health Insurance in 1926 reported that the provision of dental benefit as a statutory benefit available to all insured persons could be met only by an increase in the contributions, and nothing has since arisen in the conclusion. I am not therefore prepared to institute a special inquiry as suggested by my hon. friend.

## MEDICAL NEWS

### Society of Apothecaries of London

At recent examinations the following candidates were successful:—

*Surgery.*—O. H. Galloway, Royal Colleges, Edinburgh; L. Gottlieb, Univ. of Frankfurt and London Hosp.; M. G. H. Jones, Welsh National School of Medicine and St. Mary's Hosp.; N. Mukherjee, Univ. of Durham; M. A. Partridge, Univ. of Oxford and Guy's Hosp.; E. C. Randell, Royal Free Hosp.; C. J. S. Sergel, Univ. of Cambridge and St. Mary's Hosp.; and P. Tobin, Middlesex Hosp.

*Medicine.*—B. Jensen, Univ. of Liverpool; P. D. Lynch, Guy's Hosp.; E. C. Randell, Royal Free Hosp.; H. M. Sinclair, Univ. of Oxford and Univ. Coll. Hosp.; and J. W. Thomas, Welsh National School of Medicine.

*Forensic Medicine.*—B. Jensen, Univ. of Liverpool; P. D. Lynch, Guy's Hosp.; E. C. Randell, Royal Free Hosp.; H. M. Sinclair, Univ. of Oxford and Univ. Coll. Hosp.; H. W. Smithies, St. Mary's Hosp.; and J. W. Thomas, Welsh National School of Medicine.

*Midwifery.*—C. L. Blacklock, Univ. of Cambridge and Guy's Hosp.; J. T. Boocock, Univ. of Leeds; E. R. Brown, Guy's Hosp. and Univ. of Leeds; N. Mukherjee, Univ. of Durham; E. C. Randell, Royal Free Hosp.; F. Schwartz, Charing Cross Hosp.; H. M. Sinclair, Univ. of Oxford and Univ. Coll. Hosp.; and R. L. Williams, London Hosp.

The following candidates, having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery, and midwifery: M. G. H. Jones, P. D. Lynch, M. A. Partridge, E. C. Randell, and H. W. Smithies.

### Institute of Medical Psychology

The Sir Halley Stewart trust has granted a research fellowship for three years to this institute, and it has been awarded to Dr. Erich Wittkower for the continuation of his research on the influence of the emotions on the functions of the organs. His monograph on this subject, based on work at the Charité in Berlin, and latterly at the Maudsley Hospital, was reviewed in our issue of March 21st (p. 673).

### Chadwick [Public] Lectures

On Thursday, May 7th, at 8.15 p.m., at the Royal Institute of British Architects, 66, Portland-place, London, W., Mr. S. D. Adshead, professor of town-planning in Liverpool University, will give a lecture on London under statutory town-planning. On Thursday, June 11th, at 5 p.m., in the Chelsea Physic Garden, Swan-walk, S.W., Sir William Wilcox will lecture on plant pharmacology and medical practice. Both meetings have been arranged by the Chadwick Trust, and further information may be had from the secretary at 204, Abbey House, London, S.W.1.

Mr. G. Gordon-Taylor has been elected a corresponding fellow of the Vienna Surgical Society.

### International Congress of Dentists

We are informed that the ninth International Congress of Dentists will be held in Vienna in August, and the International Dental Exhibition, which will be held there at the same time.

### University of London Medical Graduates Society

The annual general meeting and dinner of this society will be held at the Langham Hotel, Portland-place, London, W., on Tuesday, May 12th, at 7 for 7.30 p.m., when the guest of honour will be Mr. H. L. Eason, the vice-chancellor of the University. The hon. secretary may be addressed at 38, Queen Anne-street, London, W.1.

### Demonstrations of Contraceptive Technique

On Thursday, May 7th, at 2.30 p.m., a practical demonstration of the technique of the use of a variety of contraceptive methods will be given by Mrs. Marie Stopes, D.Sc., and Dr. Evelyn Fisher. Medical practitioners and senior students only should apply for tickets to the hon. secretary of the Society and Clinic for Constructive Birth Control, 108, Whitfield-street, London, W.1.

### The Guardianship Society

At the annual meeting of this society at Brighton on April 18th the gathering stood in silence as a tribute to the memory of the late Miss Grace Woodhead, the founder and hon. secretary of the society. When she was living at Heathfield in Sussex some 35 years ago, Miss Woodhead had the idea of boarding out London children for country holidays. This drew her attention to the large number of children who were mental defectives, and in 1913, in compliance with the Mental Deficiency Act of that year, she formed the society and moved her headquarters to Brighton. The growth of the work is marked by the fact that during 1935 no fewer than 1190 cases were under the care of the society in an occupational centre, on training farms, or in charge of foster parents. Dr. S. E. Gill, formerly a commissioner of the Board of (Lunacy) Control, has taken over the duties of hon. secretary, and he is also medical director. At the meeting an address was given by Dr. F. Douglas Turner, medical superintendent of the Royal Eastern Counties Institution at Colchester. He said that the higher-grade mental defectives could with proper care and training be made fit to play a useful part in the world's affairs. The society was playing an important part in the struggle for the ideal of a resocialisation of the mentally deficient.

**King's College Hospital, London**

An anonymous donor has given £4000 of housing stock to this hospital. The money is to be available for general purposes.

**New Municipal Hospital at Huddersfield**

A site has been chosen for a new municipal hospital which is to be erected at a cost of £100,000, and is to have 160 beds with accommodation to allow extension to 250 beds.

**Gift to St. Mary's Hospital, London**

Lord Beaverbrook has given £24,900 to this hospital. In 1929 he gave £63,000 towards the rebuilding of its medical school.

**Post-graduate Course at St. Bart.'s**

A post-graduate course, open to all medical practitioners, will be held at St. Bartholomew's Hospital medical college on June 18th, 19th, and 20th. On Thursday afternoon surgical and medical cases will be shown, and there will be a pathological demonstration. Members of the course will also be welcome in the operating theatres on that afternoon. Lectures will be given on Friday by Dr. F. G. Chandler (asthma and emphysema), Mr. Basil Hume (surgical treatment of gastric and duodenal ulcers), Mr. F. C. W. Capps (diagnosis and treatment of sinusitis), Mr. S. L. Higgs (deformities of the spine), Prof. L. J. Witts (anæmia in women), and Mr. R. S. Corbett (fractures of the leg), and on Saturday by Prof. Paterson Ross (head injuries), Dr. Geoffrey Bourne (the use and action of drugs in heart failure), Mr. John Beattie (contraceptives), Mr. H. W. Rodgers (technique and uses of gastroscopy), and Dr. A. W. Spence (recent advances in hormone therapy). The course will conclude with a lecture on anæsthesia and analgesia in labour. Further information may be had from the dean of the college.

**Progress in Maternal and Child Welfare**

Sir Kingsley Wood, Minister of Health, speaking on Monday at the annual general meeting of the East End Maternity Hospital, gave figures showing the progress and results of maternity and child welfare work in England and Wales during 1935. The outstanding event of the year was the establishment of a new low record in the rate of deaths of infants under one year of age, the figure for England and Wales being 57 per 1000 live births, as against 66 in 1931, 83 in 1921, and 130 in the year 1911. The key to the reduction of infant mortality had been in particular, he thought, the education and instruction of the mother through the infant welfare centres, the health visitors, and the institutions dealing more especially with maternal care. The number of infant welfare centres had increased by 117 during the year, and now numbered over 3300. The number of children under one year of age who attended them for the first time during the year was 351,000, being 58 per cent. of the total number of births during 1935. Visits were paid by health visitors to 584,000 children under one year of age, being over 97 per cent. of the total births. It was also satisfactory, though there was need for expansion, that 588,000 children between the age of 1 and 5 years attended the centres in 1935 against 546,000 in 1934. It was a matter of concern on the other hand that the recorded rates of maternal mortality had remained comparable with those of 30 years ago. The provisional figure for 1935 of maternal deaths per 1000 live births in England and Wales had however been found to be 4·10, which compared with a rate of 4·60 for 1934, and was the lowest figure recorded since 1925 when the rate was 4·08. The actual number of maternal deaths in 1935 was 2457, or 291 less than in 1934, although the number of births in 1935 was rather more than in 1934. But there was much more to be done in investigation and endeavour. It was a gratifying fact that for the years 1921-28 the maternal mortality-rate of the patients of the East End Maternity Hospital was only 0·68 per 1000 births, and that in the seven years that followed only 21 deaths had occurred in over 13,500 confinements.

**Air Ambulances in Britain**

Speaking at the annual meeting of the Surrey branch of the British Red Cross Society at Wimbledon last Monday, Mr. S. J. Noel-Brown said that Great Britain is much behind other countries in air ambulance services; "France, Sweden, Italy, Poland, and the United States all have organised ambulance organisations, but, generally speaking, we are years behind." The society had given a valuable lead by the formation of its air ambulance detachment, and one of the leading makers of civil aircraft was completing the first British complete aeroplane to be designed and built as a flying hospital. In addition to the usual equipment of a dressing station, the machine would carry blood transfusion apparatus and an oxygen tent. The air would provide rapid and comfortable transport for the sick and injured, and it was reasonable to anticipate that in the not distant future every municipal authority possessing its own aerodrome would have its own air ambulance units.

**Appointments**

- ASHBY, W. R., M.D. Camb., D.P.M., has been appointed Pathologist, St. Andrew's Hospital, Northampton.
- BRAMLEY, G. F., M.D. Leeds, D.P.H., Medical Officer of Health for Bexley.
- LOWE, JOHN, M.D., F.R.C.S. Edin., Chief Medical Officer and Superintendent to the G.W.R. Medical Fund Society, Swindon.
- POLLITT, ALFRED, M.B. Dub., D.M.R.E., Assistant Radiologist at University College Hospital.
- Medical Referee under the Workmen's Compensation Act, 1925: GEORGE LOUIS MALCOLM SMITH, M.B., Ch.B., F.R.C.P., of Edinburgh, for the Midlothian and Peebles Sheriff Court Districts (Sheriffdom of the Lothians and Peebles).
- London County Council Hospital Staff.*—The following appointments, promotions, and transfers are announced. A.M.O. (I.) and (II.) = Assistant Medical Officer, Grades I. and II.:
- GRAY, G. M., M.B. Edin., F.R.C.S. Eng., A.M.O. (I.), St. Mary Abbots;
- BAGSHAW, H. B., M.R.C.S. Eng., F.R.C.S. Edin., A.M.O. (I.), Lambeth;
- DORLING, G. C., F.R.C.S. Eng., A.M.O. (I.), St. Alfege's;
- JAMES, CLIFFORD, M.D. Lond., A.M.O. (I.), Lewisham;
- HURFORD, J. V., M.D. Belf., D.P.H., A.M.O. (II.), Colindale;
- MCILROY, ALEXANDER, M.B. N.Z., A.M.O. (II.), New End;
- GRIFFIN, T. F. R., M.B., A.M.O. (I.), Mile End;
- FARRINGTON, G. G., M.B. Lond. A.M.O. (I.), St. George-in-the-East;
- HART, V. E. L., M.R.C.S. Eng., A.M.O. (II.), Lewisham;
- OLDAKER, JOAN M., M.B. Lond., A.M.O. (II.), St. Leonard's;
- QUINN, T. R., M.B. Sydney, F.R.C.S. Edin., House Surgeon, St. Mary Abbots;
- MCWHIRTER, J. R., M.B. Belf., House Physician, St. Luke's (Chelsea);
- HYNES, H. T. J., M.R.C.S. Eng., House Physician, Dulwich;
- BURBRIDGE, D. H. D., M.R.C.S. Eng., House Physician, St. Andrew's;
- WARDALE, ALAN, M.R.C.S. Eng., House Physician, St. Giles';
- BARNES, J. E. M., M.R.C.S. Eng., House Physician, St. James';
- BARRITT, JOHN, M.D. Irel., House Surgeon, St. James';
- HENRY, T. C., M.R.C.S. Eng., House Physician, St. James';
- STEIN, SIDNEY, M.R.C.S. Eng., House Physician, St. Giles';
- LIPPIST, W. N., M.R.C.S. Eng., House Physician, St. Olave's;
- MACLEAN, W. E., M.B., Ch.B. St. And., House Physician, St. Olave's;
- SALKFIELD, J. P., M.R.C.S. Eng., House Physician, St. Mary Abbots;
- PARK, JACK, M.B. Edin., House Surgeon, St. Mary Abbots;
- SEGALOV, COLEMAN, M.R.C.S. Eng., House Physician, St. Alfege's;
- ERSKINE, DAVID, M.B. Lond., D.P.H., House Physician, North-Western;
- WALKER, E. O., M.R.C.S. Eng., A.M.O. (II.), St. Luke's (Chelsea);
- ANDERSON, I. G., M.B. Lond., A.M.O. (II.), Lewisham;
- ROSS, J. A., M.B. Edin., A.M.O. (II.), St. Andrew's;
- CLOTHIER, JOHN G., M.B., House Physician and House Surgeon, St. Alfege's;
- LILLIS, W. J. P., L.R.C.S. Irel., Senior A.M.O. (II.), Northern;
- LOYD, E. T., M.R.C.S. Eng., D.P.H., Senior A.M.O. (II.), South-Western;
- DENNISON, F. R., M.D. Lond., D.P.H., A.M.O. (I.), Colindale;
- BRADBURY, ERIC, B.Chir. Camb., A.M.O. (I.), St. Peter's;
- BAX, E. C., B.Sc., L.M.S.S.A., A.M.O. (II.), Constance-road Institution;
- FURST, H. C., B.Sc. Sydney, L.R.C.P. & S. Edin., A.M.O. (I.), Lambeth;
- BYRNE, P. A., M.B., B.Ch., B.A.O. Dub., A.M.O. (II.), Constance-road Institution;
- BJORREBOREN, MARGARET E., M.R.C.S. Eng., D.P.H., Senior A.M.O. (II.), Northern;
- PEARCE, RICHARD, M.D. Camb., A.M.O. (I.), Paddington.

NOTES, COMMENTS, AND ABSTRACTS

JOINT LUBRICATION

BY ERIC SHIRLEY JONES, M.R.C.S. Eng.

BECAUSE the engineer has an extensive knowledge of lubrication in machine bearings, it is instructive to apply his principles to the human joint, and in a former article I described experiments which showed the value of synovial fluid as a lubricant (THE LANCET, 1934, i., 1426).

In 1886 Osborne Reynolds formulated his law<sup>1</sup> which states that a well-lubricated shaft, rotating at a fair speed, becomes separated from its bearing by a film of liquid oil, which is under pressure. The frictional resistance is then entirely due to the viscosity of the oil. Much work has since been done and present knowledge may be roughly summed up by considering a horizontal shaft, at first stationary in its bearing, and then rotating at some speed.<sup>2</sup> At rest, the shaft lies in line-contact with the bearing, so that no fluid oil intervenes and there is a form of solid contact

FIG. 1.—Transverse section of a horizontal shaft rotating in a bearing.

FIG. 3.—Graph of rate of slowing in fluid friction.

FIG. 2.—The modified Stanton pendulum. Length=7 ft. 6 in.

the shaft (w). The curve below shows the pressure. It will be noted that while the resultant acts in opposition to the load, the peak is beyond the load line on the outlet side of the film. Thus a heavily loaded shaft can rotate, literally floating on a pad of oil and having no contact with its bearing.

There are three essentials for the formation of this pressure-film: the viscosity of lubricant, the speed of rotation, and the eccentricity of the shaft.<sup>4</sup>

FIG. 4.—Graph of rate of slowing with different loads. Fluid friction.

In engineering practice all the following are known or can be calculated:—

- (a) Inlet and outlet thickness of the film.
- (b) " " temperature of the oil.
- (c) " " viscosity of the oil.
- (d) The pressure at all points in the film.

It seems probable that the physical laws which govern the behaviour of lubrication in a bearing also apply to that in a joint, and reflection on our ignorance of the matter should lead to a healthy feeling of humility. Since clearances are of the order of thousandths of an inch, it is not possible at once to decide whether there is solid or fluid friction. The relationships of friction, load, and speed, however, can be measured. In the first, friction is proportional to load and is unaffected by speed (Amonton's law<sup>5</sup>), while in the second, friction bears no relation to load, but varies with the square root of the speed.<sup>6</sup>

Some testing apparatus was needed to compare load and friction, and the Stanton pendulum<sup>7</sup> was modified (Fig. 2). The original apparatus was used by the late Dr. Stanton at the National Physical Laboratory for the study of friction in heavily loaded bearings and consists of a heavy pendulum swinging through a few degrees with the bearing under test as its pivot. The proximal interphalangeal joint of an amputated finger replaced the bearing; the middle phalanx was fixed, and the proximal phalanx was clamped to the side members of the pendulum. By studying the way in which it slows down, it is possible to see how the friction varies, and whether it is proportional or not to the fixed load.

It has been shown that if friction does not vary both the time and the loss of swing will be the same for each oscillation. It follows that a graph of the slowing down will show that a straight line can be drawn through the extreme points of all the swings. This is the criterion of solid friction. Should the friction, however, be related to a speed

COEFFICIENT OF FRICTION OF INTERPHALANGEAL JOINT. (LOAD, 13 LB. 5 OZ.; TEMP., 54° F.)

Angle of swing, degrees .. .. .	4.0	3.5	3.0	2.5	2.0	1.5	1.0	0.5
Number of oscillations per half degree .. .. .	11	13	16	21	27	38	56	
Coefficient of friction .. .. .	0.114	0.097	0.079	0.060	0.047	0.033	0.022	
Rubbing speed, ins. per min. .. .. .	0.8	0.8	0.7	0.6	0.5	0.3	0.2	

that is steadily falling, a curve will result, since the friction tending to stop the motion will decrease with the speed (Fig. 3). This is to be expected where fluid friction is the stopping force.

The pendulum was first swung from a knife-edge to discover the effect of air resistance and this was found to be negligible. Fig. 4 shows the type of swing obtained with loads from 9 lb. to 228 lb., and it will be noted that all are curved, meaning that fluid film lubrication occurred in all throughout the main part of the swing. The result in the heaviest load (228 lb.) is particularly noteworthy, as it amounts to a surface pressure of about 900 lb. per sq. in. At this load crushing of bone set in. The coefficients of friction—

$$\mu = \frac{\text{friction}}{\text{load}}$$

can be calculated and these have been added in the Table. Mr. C. Jakeman, of the National Physical Laboratory, has kindly examined the curves, and believes that they represent mixed lubrication—i.e., a fluid film during movement and solid friction at the starting and stopping points. It seems to follow from Reynolds's law that there can be no fluid film between the surfaces while at rest or at the moment of beginning movement before the film has had time to form. There must then be some kind of solid friction, but the nature of this is not known. There may be friction equivalent to that between dry articular cartilage, or some form of "boundary" or "greasy" friction, for Timbrell Fisher has shown<sup>8</sup> that there is mucin inside the articular cartilage.

An inherent defect of the apparatus is that it allows one to estimate the friction only for a complete swing, and *not* that at the middle or end. A machine is now being made to allow the friction to be read at all points of the cycle of movement, and it is hoped to communicate results when they become available.

#### CONCLUSIONS

1. Fluid film lubrication is the usual form of lubrication in human joints.
2. The pressure-film is dependent for its formation upon (a) viscosity of lubricant, (b) speed of surfaces, (c) eccentricity of surfaces.<sup>9</sup>
3. The film survives a load which can crush bone.
4. Some form of solid friction must occur when speed and/or eccentricity are not enough to maintain a pressure-film.

The coefficients of friction so far obtained are high compared with those in machinery, but there was a high viscosity of the lubricant because the experiments were carried out at a temperature many degrees below that of the body.

My thanks are due to Mr. Dee, of Birmingham University, Mr. C. Jakeman, of the National Physical Laboratory, and Mr. E. C. Ulrich.

#### HOSPITAL "CALL-SYSTEMS"

THE ancient sport of finding the house surgeon, played in various ways in different hospitals, is more or less difficult according to the technique employed and the size of the hospital. The system still obtains, in at least one large hospital, of using one or more porters as bloodhounds to track down the victim. These sleuths are forbidden to return to the base until they have delivered their message and the sight of them, travel-stained, weary, and hopelessly out of scent, is an all too common one. Improvements in this primitive and labour-wasting device has been made and in certain hospitals in the United States loud speakers, operated from the telephone-board, are fixed in the corridors. Two obvious disadvantages of the loud-speaker system are that it is impossible to call several persons simultaneously and that it disturbs the quiet so much to be desired in a hospital. The call-system, with signal-boards bearing electrically illuminated numbers, is better than the loud-speaker, but some time may elapse before the victim sees that his number is up; though doubtless, should he try to turn a blind eye, kind friends will hasten to point it out to him.

Mr. H. Ekman, chief engineer of the electric plants of the fire-brigade in Stockholm, has ingeniously improved the above system, and an account of his method, supplied by Prof. Einar Key, appears in the February issue of the *Hospital*. In every possible haunt of the house surgeon (or other person likely to be wanted at short notice) there is a marking-cabinet on which is a number of buttons, each marked with the name of one of the persons incorporated in the system. At the telephone-board is a "call" or "seeker" table furnished with a like number of similarly marked buttons. There is also, in full view of the operator, a light-signal table with a signal-lamp for each haunt (ward, operating-theatre, laboratory, &c.). The house surgeon, Mr. X, notifies his entrance to any particular haunt by pressing his button on the marking-cabinet. Should Mr. X be wanted, the operator presses the button marked X on the call table and the signal-lamp of the ward in which Mr. X last pressed his button lights up. At the Maria Hospital, Stockholm, the device has been still further improved. If the house surgeon is called by the operator and has neglected to check in anywhere by pressing his button, the next time he does press a button he receives not, as might be supposed, the shock he deserves but a buzzing signal which tells him that he is wanted. By pressing a special cancellation button he may temporarily "sport his oak" and cease to exist so far as the system is concerned. On the other hand, he may do so unwittingly by neglecting to indicate a fresh location and so become temporarily and inconveniently "lost."

A still more recent attempt has been made to improve on the above system by using display panels showing a double row of lamps. On one row, each lamp represents a calling party; on the other, an official required. To draw attention to the display, signals audible but not loud enough to disturb the patients or intermittent flashes are used, the whole being under the control of a telephone operator. This system, which is described in the April issue of the *Hospital*, can only call one person at a time, but appears to be the best so far devised. To the frivolously inclined these light-signal systems seem to offer facilities for practical joking on a large scale. As to what might happen were the apparatus to become slightly deranged so that everybody received somebody else's call, we must leave to the imagination.

#### PREDISPOSING CAUSES OF UTERINE CANCER

IN a study of 982 cases of carcinoma of the uterus, comprising 879 of cancer of the cervix and 103 of cancer of the body, P. Natale endeavours to determine the aetiological factors concerned (Tumori, 1935, ix., 185). He decides that the following are of minor importance: race, social position, functional dis-

turbances of the uterus or ovaries, sexual abuse, heredity, and individual constitution. As regards age, he emphasises that carcinoma of the uterus may develop at any period of life; in the present series the maximal incidence was at 50-54, while if cervical and corporal cases were separately considered, the former showed the highest incidence between 40 and 54, the latter between 60 and 64. Natale reaches the common conclusion that the most important predisposing factor is some antecedent lesion of the cervix, especially of an inflammatory character. A history suggestive of chronic cervicitis was obtained in a very large proportion of the cases of cancer of the cervix, and since none of these women had had any medical or operative treatment for the former condition, he believes that many of them would have been saved from developing carcinoma had such treatment been carried out. To support this view he quotes Bossi, who in a series of 7000 cases of plastic operations on the cervix, followed up for many years, had no cases of subsequent cancer. Unlike most investigators, Natale finds that multiparity has little influence upon the incidence of cervical carcinoma; of his 879 patients as many as 132 (15 per cent.) had borne no children. On the other hand, the 103 cases of cancer of the body of the uterus included 40 (38 per cent.) nulliparæ.

**PLACENTAL EXTRACT IN MEASLES.**—The Bioglan Laboratories, Ponsbourne Manor, Hertford, inform us that they are willing to supply Embryonin, a placental extract, to hospitals that wish to test its value in the prophylaxis of measles.

**SAN TOOTHBRUSH.**—One of the chief disadvantages of a toothbrush is that parts of the teeth are inaccessible to its action. It is difficult to remove the stagnant detritus accumulated in the inter-spaces, and the adjacent surfaces cannot be cleaned. The San toothbrush is constructed to overcome this in a simple way. Very similar to many brushes in common use, it differs in one particular—the end of the handle is U-shaped. The resilient prongs are notched and a thread can be fixed so that a length of about  $\frac{3}{4}$  in. is held taut by the notches. This can be passed to and fro between the teeth. Besides cleaning, another useful purpose is served when fraying of the smooth thread reveals a sharp surface, the result of hidden decay. The makers (S. Aki Shoten, 30, City-road, London, E.C.1) also supply lengths of floss silk that have been treated with an abrasive dentifrice.

## Vacancies

For further information refer to the advertisement columns

- Accrington, Victoria Hospital.—H.S. £150.  
 Acton Hospital, W.—Hon. Cons. Physician.  
 Altrincham General Hospital.—Jun. H.S. At rate of £120.  
 Belfast, Forster Green Hospital, Fortbreda.—H.P. At rate of £150.  
 Birkenhead Education Committee.—Asst. School M.O. £500.  
 Birmingham and Midland Eye Hospital.—Res. Surg. O. £200.  
 Birmingham, Selly Oak Hospital.—Jun. M.O. At rate of £200.  
 Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. At rate of £120.  
 Brighton, New Sussex Hospital for Women, Windlesham-road.—H.S. £100.  
 Brighton, Royal Alexandra Hospital for Sick Children.—H.P. £120.  
 Bristol City and County Mental Hospital.—Med. Supt. £1000.  
 Burton-on-Trent, General Infirmary.—H.P. and Cas. O. £150.  
 Cambridge, Addenbrooke's Hospital.—Res. Surg. O. £225. Also H.P. At rate of £130.  
 Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Assts. in Out-patient Dept.  
 Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall, Gt. Barrow.—H.P. At rate of £150.  
 City of London Hospital for Diseases of the Heart and Lungs Victoria Park, E.—Med. Reg.  
 Coventry, Gulsong-road Municipal Hospital.—2nd Asst. Res. M.O. £250.  
 Deansbury County Borough.—M.O.H. and School M.O. £900.  
 Doncaster, Royal Infirmary and Dispensary.—H.S. At rate of £175.  
 Durham County Council.—District Tuber. M.O. £500.  
 Eastbourne, Royal Eye Hospital, Pevensey-road.—H.S. £275.  
 Epsom County Hospital.—Res. Asst. M.O. At rate of £375.  
 Evelina Hospital for Sick Children, Southwark, S.E.—Part-time Pathologist. £250-£300.  
 Exeter, Devon Mental Hospital, Exminster.—Jun. Asst. M.O. £350.  
 Fareham, Hants, Knowle Mental Hospital.—Deputy Med. Supt. £700.  
 Folkestone, Royal Victoria Hospital.—Jun. Res. M.O. At rate of £120.  
 Glasgow, Southern General Hospital.—Deputy Med. Supt. £500.  
 Gordon Hospital for Rectal Diseases, Vauxhall Bridge-road, S.W.—Res. H.S. At rate of £150.  
 Guildford, Royal Surrey County Hospital.—H.S. £150.  
 Hertford County Hospital.—H.S. At rate of £180.  
 Hospital for Sick Children, Great Ormond-street, W.C.—Res. H.P. and Res. H.S. Each at rate of £100.  
 Hull Royal Infirmary.—H.S. to Ophth. and Ear, Nose, and Throat Dept. Also Second Cas. O. Each at rate of £150.  
 Ipswich, East Suffolk and Ipswich Hospital.—Orthopaedic Surgeon. £500.  
 Ipswich Mental Hospital.—H.P. At rate of £150.  
 Isolation Hospital, Muswell Hill, N.—Res. M.O. £500.  
 Kidderminster and District General Hospital.—H.S. £150.  
 Kilmarnock Infirmary.—H.P. and H.S. Each £110.  
 Kingston District Hospital.—Res. Asst. M.O. At rate of £375.  
 Leeds, St. James's Hospital.—Res. M.O. Also Res. Surg. O. Each £350.  
 Leicester Royal Infirmary.—Hon. Asst. Radiologist. Also Visiting Anaesthetist.  
 Liverpool, Stanley Hospital.—H.S. At rate of £100.  
 Liverpool University.—Lecturer in Dept. of Bacteriology £600-£700.  
 Llanelly and District Hospital.—H.S. £150.  
 London Child Guidance Clinic, 1, Canonbury-place, N.—Three Fellowships in Psychiatry. Each £300.  
 London County Council.—Asst. M.O. £600. Sen. Asst. M.O.'s, Grade II. Each £500. Also Asst. M.O., Grade II. £250.  
 London Homoeopathic Hospital, Great Ormond-street, W.C.—H.S. At rate of £100.  
 London (R.F.H.) School of Medicine for Women, Hunter-street, W.C.—Demonstrator in Physiology. £250-£300.  
 Macclesfield General Infirmary.—Sen. H.S. At rate of £180.  
 Manchester, Ancoats Hospital.—H.S. for Ear, Nose, and Throat Dept. At rate of £100.  
 Manchester City.—Vacancies on Consultant Medical, Surgical, &c., Staffs of Municipal Hospitals. £125-£400.  
 Manchester Royal Children's Hospital, Pendlebury.—Res. Surg. O. At rate of £125.  
 Manchester Royal Infirmary.—Hon. Asst. Surgeon. Also H.S. At rate of £50.  
 Manchester, Victoria Memorial Jewish Hospital, Cheetham.—Cas. O. At rate of £125.  
 Manor House Hospital, Golders Green, N.W.—Jun. M.O. £200.  
 Margate, Royal Sea-Bathing Hospital.—H.S. At rate of £200.  
 Mount Vernon Hospital, Northwood.—H.S. At rate of £150.  
 National Temperance Hospital, Hampstead-road, N.W.—H.P. At rate of £100.  
 Newcastle-upon-Tyne Hospital for Sick Children.—Hon. Physician to Skin Dept.  
 Northampton General Hospital.—H.S. At rate of £150.  
 North Riding of Yorkshire C.C.—County M.O.H. and School M.O. £1200.  
 Norwich, Norfolk and Norwich Hospital.—H.S. Also Cas. O. Each £120.  
 Oxford, Wingfield-Morris Orthopaedic Hospital, Headington.—Lord Nuffield Scholarship in Orthopaedic Surgery. £200.  
 Plymouth, Prince of Wales's Hospital, Greenbank-road.—H.S. At rate of £120.  
 Preston, Whiston Public Assistance Institution, near Prescot.—Visiting Surgeon. £450.  
 Princess Louise Kensington Hospital for Children, St. Quintin-avenue, W.—H.S. At rate of £100.  
 Queen's Hospital for Children, Hackney-road, E.—H.P. and Cas. O. Each at rate of £100. Also Clin. Asst. to Surgical Out-patients. 5s. per attendance.  
 Redhill, Royal Earlswood Institution.—Jun. Asst. M.O. At rate of £250.  
 Rotherham, Oakwood Hall Sanatorium.—Asst. M.O. £300.  
 Royal Free Hospital, Gray's Inn-road, W.C.—Asst. M.O. £350.  
 Royal Naval Medical Service.—M.O.'s.  
 Royal Northern Hospital, Holloway, N.—H.S. and H.P. Each at rate of £70.  
 Royal Society of Medicine, 1, Wimpole-street, W.—Nichols Fellowship. £150.  
 St. Bartholomew's Hospital, E.C.—Surgeon.  
 St. John's Hospital, Lewisham, S.E. S.E.—Hon. Ophth. Reg.  
 Sheffield Royal Infirmary.—Ophth. H.S. At rate of £120.  
 Southampton Isolation Hospital and Sanatorium.—Jun. Res. M.O. £200.  
 Southampton, Royal South Hants and Southampton Hospital.—Sen. H.S. £200. H.P. H.S. Also Res. Anaesthetist and H.S. to Ear, Nose, and Throat Dept. Each at rate of £150.  
 Stafford, Prestwood Sanatorium.—Jun. Asst. M.O. £250.  
 Stoke-on-Trent City.—Asst. Tuber. O. £500.  
 Sunderland Royal Infirmary.—H.S. and H.P. Each £120.  
 Surrey County Council.—Asst. M.O. £600.  
 Swansea General and Eye Hospital.—H.P. and Cas. O. Each at rate of £175.  
 Warwickshire and Coventry Mental Hospital.—Med. Supt. £1200.  
 Wembley U.D.C.—M.O.H. £1000.  
 Western Ophthalmic Hospital, Marylebone-road, N.W.—Hon. Asst. Surgeon.  
 Wolverhampton Royal Hospital.—H.P. At rate of £125.  
 Woolwich and District War Memorial Hospital, Shooter's Hill, S.E.—Hon. Asst. Obstet. Surgeon. Also two H.S.'s. Each at rate of £100.  
 York County Hospital.—H.P. £150.  
 The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Penarth (Glamorgan) and Old Deer (Aberdeen).

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

### SOCIETIES

- ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.**  
**TUESDAY, May 5th.**  
*Orthopaedics.* 5.30 P.M. (Cases at 4.30 P.M.) Annual General Meeting. Mr. Laming Evans: 1. Osteochondritis of Lower Epiphysis of Femur. Mr. V. H. Ellis: 2. Pathological Fracture of the Tibia. Mr. H. J. Seddon: 3. Empyema Secondary to a Tuberculous Spinal Abscess. 4. Rupture of a Tuberculous Spinal Abscess into the Oesophagus.
- WEDNESDAY.**  
*History of Medicine* 5 P.M. Annual General Meeting. Dr. J. A. Glover: Finding an Asklepiion, and Some Minor Archeological Adventures in a Doctor's Life. *Surgery.* 5.30 P.M. Annual General Meeting.
- THURSDAY.**  
*Tropical Diseases and Parasitology.* 8.15 P.M. Dr. P. H. Manson-Bahr: The Diagnosis and Treatment of Dysentery and Colitis in Tropical Practice. (Presidential Address.)
- FRIDAY.**  
*Clinical.* 5.30 P.M. (Cases at 4.30 P.M.) Annual General Meeting. Cases. Dr. M. L. Rosenheim (for Dr. J. W. McNee): 1. Myxoedema Strongly Resistant to Thyroid Treatment. Dr. J. H. Lawrence (for Dr. McNee): 2. Extraordinary Recurrent Pyrexia of Over Two Years' Duration. Dr. Philip Ellman: 3. Bilateral Pulmonary Tuberculosis Treated by: (a) Partial Artificial Pneumothorax for the Right Lung. (b) Thoracoplasty for the Left Lung. (c) Insulin.
- MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY.**  
**THURSDAY, May 7th.**—8 P.M. (B.M.A. House, Tavistock-square, W.C.), Dr. Alfred Adler: The Psychological Approach.
- WEST KENT MEDICO-CHIRURGICAL SOCIETY.**  
**FRIDAY, May 8th.**—8.45 P.M. (Miller General Hospital, Greenwich), Dr. J. R. Wylie: The Functions of a Radiologist. (Presidential Address.)
- BIOCHEMICAL SOCIETY.**  
**SATURDAY, May 9th.**—2.45 P.M. (Rockefeller Department of Biochemistry, Museum, Oxford), Short Communications and Demonstrations.
- LECTURES, ADDRESSES, DEMONSTRATIONS, &c.**
- UNIVERSITY OF LONDON.**  
**TUESDAY, May 5th. THURSDAY, and FRIDAY.**—5.30 P.M. (London School of Hygiene, Keppel-street, W.C.), Prof. A. Butenandt: Biochemistry of the Sterol Group.
- BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducaun-road, W.**  
**MONDAY, May 4th.**—2.15 P.M., Dr. Duncan White: Radiological Demonstration. 3.30 P.M., Prof. R. W. Johnstone: Hormone Therapy in Gynaecology.  
**TUESDAY.**—2 P.M., Prof. E. H. Kettle: Pathological Demonstration. 3 P.M., Dr. Janet Vaughan: The Monocyte-lymphocyte Ratio.  
**WEDNESDAY.**—Noon, Clinical and pathological conference (medical). 2.30 P.M., Clinical and pathological conference (surgical).  
**THURSDAY.**—2.30 P.M., Dr. W. S. C. Copeman: Arthritis. 3 P.M., Dr. Chassar Moir: Operative Obstetrics. 2.30 P.M., Sir Henry Gauvain: Surgical Tuberculosis.  
**FRIDAY.**—2.15 P.M., Dr. A. A. Davis: Gynecological Pathology.  
 Daily, 10 A.M. to 4 P.M., medical clinics, surgical clinics or operations, obstetric and gynecological clinics or operations, refresher course for general practitioners.
- FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.**  
**MONDAY, May 4th, to SUNDAY, May 10th.**—St. John's Hospital, Lisle-street, W.C. Afternoon course in dermatology.—BROMPTON HOSPITAL, S.W.3. Sat. and Sun., course in chest diseases.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. All-day course in medicine, surgery, and gynecology.—MAUDSLEY HOSPITAL, Denmark Hill, S.E. Afternoon course in psychological medicine.—Courses open only to members of the Fellowship.
- INSTITUTE OF MEDICAL PSYCHOLOGY, Malet-place, W.C.**  
**SATURDAY, May 9th.**—11.30 A.M., Dr. Laura Hutton: Common Disorders in School Life. 2 P.M., Dr. J. A. Haddfield: Origin of Psychopathological Conditions in Early Childhood. 3.15 P.M., Dr. Grace Calver: Diagnostic and Therapeutic Methods. 5 P.M., Dr. Emanuel Miller: Common Behaviour Disorders of Early Childhood and their Treatment.  
**SUNDAY.**—11 A.M., Dr. E. A. Hamilton-Pearson: Physiological and Temperamental Factors in the Aetiology of Childhood Disorders. Noon.—1 P.M., General Discussion on Course.
- LONDON SCHOOL OF DERMATOLOGY, 5, Lisle-street, W.C.**  
**MONDAY, May 4th.**—5 P.M., Dr. S. E. Dore: Epidiascope Demonstration of Skin Diseases.  
**TUESDAY.**—5 P.M., Dr. H. Thompson Barron: Common Skin Diseases in Childhood.

- THURSDAY.**—5 P.M., Dr. J. M. H. MacLeod: Infections of the Skin with Yeast-like Organisms.  
**FRIDAY.**—5 P.M., Dr. W. K. Sibley: Alopecia.  
**HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.**  
**WEDNESDAY, May 6th.**—2 P.M., Dr. R. T. Brain: Endogenous Factors in Eczema. 3 P.M., Dr. A. Signy: Intestinal Parasites.  
 Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.  
**NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W.**  
**TUESDAY, May 5th.**—5.30 P.M., Dr. D. Evan Bedford: The Thyrototoxic Heart and its Treatment.  
**UNIVERSITY OF BIRMINGHAM.**  
**TUESDAY, May 5th.**—3.30 P.M. (Children's Hospital), Prof. Leonard Parsons: Demonstration of Cases of Diseases of Children.  
**THURSDAY.**—4 P.M. (Medical Faculty Buildings), Mr. Percival Hartley, D.Sc.: The Chemistry of Antigens and Antibodies. (Second William Withering lecture.)  
**FRIDAY.**—3.30 P.M. (Queen's Hospital), Mr. Harold Round: Teeth from the Points of View of the General Medical and Dental Practitioner.  
**MANCHESTER ROYAL INFIRMARY.**  
**TUESDAY, May 5th.**—4.15 P.M., Dr. W. Fletcher Shaw: The Use of Radium in Gynaecology.  
**FRIDAY.**—4.15 P.M., Dr. P. B. Mumford: Demonstration of Common Dermatological Conditions.  
**GLASGOW POST-GRADUATE MEDICAL ASSOCIATION**  
**WEDNESDAY, May 6th.**—4.15 P.M. (Royal Hospital for Sick Children), Dr. Stanley Graham: Gastro-enteritis in Childhood.

## Births, Marriages, and Deaths

### BIRTHS

- ALLEN.**—On April 22nd, at Fulwood, Shotley Bridge, the wife of Dr. R. Barclay Allen, of a daughter.  
**FOTHERGILL.**—On April 18th, at Ambleside, Westmorland, the wife of Dr. E. L. Fothergill, of a daughter.  
**HILLMAN.**—On April 23rd, at Newlands, Liss, the wife of O. Stanley Hillman, M.S., F.R.C.S., of Southsea, of a daughter.  
**HOUSE.**—On April 19th, the wife of Arthur House, M.R.C.S. Eng., of Bicester, Oxon., of a daughter.  
**HUMPHRIS.**—On April 25th, at King's Lynn, the wife of Dr. J. Howard Humphris, of a daughter.  
**LAWRENCE.**—On April 21st, at Albert Bridge-road, London, the wife of Dr. R. D. Lawrence, of a son.  
**MACIVER.**—On April 21st, at Edinburgh, the wife of D. P. Maciver, M.C., M.D. Edin., of a son.  
**REES.**—On April 24th, at Cardiff, the wife of Dr. Edward J. Rees, Pontypridd, of a son.  
**RUTHERFORD.**—On April 20th, at Longtown, Cumberland, the wife of Robert Rutherford, F.R.C.S. Eng., of a daughter.  
**SPENCER.**—On April 20th, at Chorley, Lancs, the wife of Dr. John Spencer, of a daughter.  
**STEELE-PERKINS.**—On April 23rd, at Rosemont, Exeter, the wife of Dr. Guy Steele-Perkins, of a son.

### MARRIAGES

- FLAVEL—LITTLEJOHN.**—On April 18th, at St. John's Church, Alton, Staffordshire, Sidney William Flavel to Mary Victoria Littlejohn, M.B. Aberd., D.P.H.  
**MIN SEIN—YIN MAY.**—On March 15th, at Rangoon, Burma, Captain Min Sein, M.B. Cal., M.R.C.P. Lond., I.M.S., to Ma Yin May, M.B. Cal., M.R.C.P., and F.R.C.S. Edin.  
**SHEARER—DANN.**—On April 24th, in London, Gavin Shearer, M.B. Glasg., Colonial Medical Service, Nigeria, to Rita Mary, eldest daughter of Major E. W. Dann, Reading.  
**SNELL—SUTHERLAND-HARRIS.**—On April 25th, at Burwash Parish Church, Vincent Clark Snell, F.R.C.S. Eng., to Joan Sutherland-Harris, of Heathfield, Sussex.  
**TAIT—POPE.**—On April 22nd, at Holy Trinity Church, Exmouth, Charles Brooke Vaughan Tait, M.B. Lond., D.O.M.S., to Roselle Mary Gladstone Pope, only daughter of the late P. G. Pope and Mrs. Pope, of Exeter.

### DEATHS

- ARMSTRONG.**—On April 14th, at Singida, East Africa, James Septimus Armstrong, M.B. Dub.  
**CARDALE.**—On April 22nd, at Glongall-road, Isle of Dogs, Henry Jasper Cardale, M.B. Edin., in his 66th year.  
**CARLESS.**—On Monday, April 27th, at Worthing, Albert Carless, C.B.E., M.S. Lond., F.R.C.S. Eng., of Overdale, Crief, Perthshire, in his 74th year.  
**HERRINGHAM.**—On April 23rd, at his sister's home, Lyminster, Hants, Major-General Sir Wilmot Parker Herringham, K.C.M.G., C.B., D.M. Oxon., F.R.C.P. Lond., in his 81st year.  
**JACKSON.**—On April 26th, suddenly, at Esher, John William Jackson, M.B. Glasg., late of Shanghai.  
**LOCK.**—On April 21st, in Chelmsford Hospital, the Rev. Lyonel John Lock, M.A. Camb., M.R.C.S. Eng., Rector of Walsoken Norfolk.  
**MASON.**—On April 23rd, at Northallerton, Harry Mason, M.B. Edin., D.P.H., County Medical Officer of Health, North Riding, Yorkshire, aged 59.  
**RUTHERFORD.**—On April 22nd, at Overstrand, Norfolk, Allan Freer Rutherford, M.B. Edin.  
**SEYMOUR.**—On April 15th, at Redhill, Lionel William Seymour, M.R.C.S. Eng., late of Oxford and of Sind Survey, son of Capt. L. W. Seymour, Bombay Light Cavalry, E.I.C., aged 81.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## ADDRESSES AND ORIGINAL ARTICLES

## EXTIRPATION OF THE LUNG\*

By GEORGE A. MASON, M.B. Durh., F.R.C.S. Eng.  
HONORARY ASSISTANT SURGEON TO THE HOSPITAL FOR SICK  
CHILDREN, NEWCASTLE-UPON-TYNE; THORACIC SURGEON TO  
THE NEWCASTLE GENERAL HOSPITAL AND THE  
SUNDERLAND MUNICIPAL HOSPITAL

(WITH ILLUSTRATIVE PLATE)

CERTAIN patients with unilateral pulmonary disease not amenable to other therapeutic measures, for whom the outlook is otherwise hopeless, may be relieved or even cured by removal of the affected organ.

Sauerbruch and the German school, with true international courtesy, credit Macewen<sup>1</sup> with the first successful operation of this kind in 1895; but the published account of this case reveals that although the necrotic remnants of a broken-down tuberculous lung were removed in several stages, no formal pneumonectomy, in the modern sense, was performed; the hilus was not interfered with, and it was considered inadvisable to remove the adherent apex completely. Another interesting case is that reported by Sauerbruch<sup>2</sup> in 1923; accidental interference with the blood-supply of the left lung during removal of a large ganglioneuroma from the posterior mediastinum of a young woman led to necrosis of the whole lung, the sloughs of which were removed, and the patient recovered.

A host of investigators, commencing with Gluck<sup>3</sup> in 1881, demonstrated the possibility of the successful extirpation of an entire lung in the experimental animal. Thirty years later Kümmell<sup>4</sup> performed the operation, but unsuccessfully, in man, and although others, notably Meyer,<sup>5</sup> Lilienthal,<sup>6</sup> and Archibald,<sup>7</sup> repeated the attempt, it was never successful until a further twenty years had elapsed—i.e., in 1931, when Nissen,<sup>8</sup> working in Sauerbruch's clinic in Berlin, resected the entire left lung of a girl of 12, who was suffering from bronchiectasis secondary to a traumatic rupture of the left main bronchus. In the following year Haight,<sup>9</sup> working in Alexander's clinic in Michigan, repeated this success when he removed the entire left lung of a girl of 13, in whom bronchiectasis had followed delayed removal of an aspirated foreign body.

The greater risk of sepsis may possibly make the operation more hazardous for bronchiectasis than for neoplastic disease, and although additional successes have been reported during the last three years, these have been mostly with growths.

A year ago a preliminary report was published of two of my cases in each of which an entire lung had been successfully removed some months previously for bronchiectasis.<sup>10</sup> About the same time, in an issue of the *Post-Graduate Medical Journal*, specially devoted to lung surgery, the most radical treatment suggested for bronchiectasis involving more than one lobe, even when unilateral, was thoracoplasty. The successful cases of pneumonectomy recorded by Tudor Edwards and Roberts<sup>11</sup> show that this view is no longer held. Ferrari<sup>12</sup> and Haight have both published excellent papers in which the relevant literature is critically reviewed, and reference to which is well worth while.

A personal series of six cases of bronchiectasis in

which a whole lung has been extirpated, in four with success, is the experience on which this communication is based. Additional experience, derived from a considerably larger series in which lobectomy only was performed, is also drawn upon when necessary.

## Indications

Pulmonary diseases for which this operation may be required include gangrene, suppuration, tuberculosis, and new growth.

*Gangrene* of the lung is frequently found without any considerable degree of adhesion-formation between it and the parietes. As yet no opportunity has arisen, but I am impressed with the probability in these cases of success attending the application of mass ligatures to the hilus and amputation of the gangrenous mass beyond.

*Suppurative diseases* of the lungs include congenital multicystic lung, unresolved pneumonia, and multiple pulmonary abscesses, with or without some degree of accompanying bronchial dilatations; it is to these pathologically diverse yet clinically similar conditions that the term bronchiectasis is loosely, but at present often conveniently, applied. Their gravity is such that the indications for extirpation are necessarily elastic, it being for some of them the only form of curative treatment.

"Dry" cases are naturally among those most likely to survive operation, and this is generally advised. Its recommendation is of much more importance if hæmoptysis has occurred, or if the case has once been "wet," because relapse is likely. Here it should be mentioned that in clinically "dry" cases it is not unusual to find quantities of purulent secretion expressed into the bronchus during operative manipulations of the lung, even if it has been collapsed for some time. Constitutional treatment and postural drainage are employed in an endeavour to abolish or diminish sputum production before operation, but too much time can be wasted over such measures. Tonsillectomy may be a dangerous preliminary measure, for the operation area may be readily infected by the sputum. Vaccine therapy is advocated by some, but in my experience no improvement has followed other than could be accounted for by the measures already alluded to; nor have I observed any favourable influence exerted thus on the post-operative course. Artificial pneumothorax, pleural tamponnage, extrapleural pneumolysis (plombage), phrenic paralysis, and thoracoplasty are amongst the measures available to collapse a lung, and on occasion they prove useful by diminishing the previously excessive production of sputum before proceeding to the major operation.

A history of a previous empyema, in connexion with the affected lung, has not proved a contra-indication to operation. The adhesions in such cases, although generalised, are more often than not easily separated.

Occasionally cases are encountered in which bronchography shows one lung to be replaced by large saccular cavities, while there is a less serious but similar condition in the contralateral lobe. At present in such cases collapse therapy, rather than extirpation, seems indicated and, indeed, sometimes does give considerable relief by diminishing expectoration.

*Tuberculosis* when strictly unilateral seems to offer scope for this operation. Macewen's case has already been referred to. Although not a pneumonectomy in the modern technical sense of the word,

\* Based on a Hunterian lecture delivered before the Royal College of Surgeons of England on Jan. 31st, 1936.

it was one to all other intents and purposes. It demonstrated not only the possibility of even a gross tuberculosis lesion being unilateral, but also the possibility of the patient's survival for many years of active life after its successful elimination. The increasing popularity of the conservative—and hence apparently safer—collapse therapy has diverted interest from the possibility of extirpation. It has gradually become appreciated, however, that many cases, especially those of a predominantly “exudative” nature, are unsuitable for such treatment, and it is for this material that more radical measures may possibly be adopted with success. Actually Reinhoff,<sup>13</sup> adopting a technique to be mentioned subsequently, has successfully resected an entire lung for tuberculosis.

*New growths* of the lung are being recognised with increasing frequency. The situation of most of them, malignant or benign, is usually such as to preclude lobectomy. Further, complete removal of an organ affected with malignant disease is a generally accepted principle in surgery. The vast majority of these growths have progressed beyond the bounds of legitimate surgical enterprise when first seen by the thoracic surgeon; this has been my own experience, but Graham,<sup>14</sup> Archibald, and Reinhoff,<sup>15</sup> among others, have successfully resected lungs thus affected.

When hæmoptysis, abnormal expectoration, &c., are regarded as symptoms requiring investigation just as urgently as hæmaturia or optic neuritis, many cases will be diagnosed during a phase amenable to extirpation.

#### Technique

*Anæsthesia* is obtained with either chloroform or ether vapour and oxygen, administered by the intratracheal method to facilitate both the use of differential pressure and the evacuation, when necessary, of sputum. The patients in this series being young, Avertin was employed in each as a preliminary basal narcotic: Omnopon-scopolamine is preferable as a sedative before operation in older subjects.

The approach is usually by a posterolateral incision through an intercostal space, the patient lying on the opposite side with a sandbag under the chest. A long incision extending from the spine almost to the sternum was employed in the first three cases of the present series; this crossed the lower end of the scapula, which was then retracted to permit access between the 5th and 6th ribs: a shorter incision below the angle of the scapula sufficed in the later cases. Forcible separation of the ribs by a suitable retractor gives adequate exposure, but with a shorter incision it is advisable to divide or, better still, to resect subperiosteally small portions of the adjacent ribs. More extensive costal resections may be required with chest walls of a more rigid type.

An incision which, although similar, is predominantly anterior, is required for those cases in which a formal dissection of the individual elements in the hilus is undertaken.

Incisions entailing the use of an osteoplastic flap have been generally discarded, but such an incision is an essential feature of the method suggested and described by Ferrari,<sup>12</sup> “la exoneumopexia extrapleurale”; through this incision, after mobilising the lung and ligaturing its hilus, extensive subperiosteal resections of the ribs are carried out transpleurally. Thus, the cavity being obliterated, it is possible to exteriorise the exsanguinated lung which subsequently sloughs off. The lung is mobilised by

division of the pulmonary ligament and of such adhesions as may be encountered.

There are three methods by which the actual removal of the lung may be effected:

1. A careful dissection is made of the pulmonary pedicle, the vascular elements are divided between ligatures, and the bronchus, having been divided at a convenient level, is closed by interrupted sutures to allow approximation. The chest is then closed. This method should be employed in neoplastic disease, being the most radical and hence approximating most closely to the ideal for such cases. An artificial pneumothorax may with advantage be induced and maintained during the ten or fourteen days preceding operation. Adhesions render the operation difficult, and it should be avoided where there is reason to suspect any induration of the pedicle, the thin-walled vessels being only too easily lacerated, and, under such circumstances, difficult to control.

Reinhoff,<sup>13 15</sup> using this technique, had performed successfully five such operations before February last year. All, except one which was for tuberculosis, were for growths. The youngest patient was aged 3, and the oldest 70.

2. The Brunn-Shenstone technique for lobectomy may be applied to these cases. The pulmonary pedicle being controlled by either a tourniquet or a clamp, the lung itself is then amputated about  $\frac{3}{4}$  in. beyond this. A series of hæmostatic and stay sutures are used to transfix the vascular and bronchial elements in the pedicle, such parenchyma as may be available is utilised to cover over the stump by suturing. The chest is then closed, and airtight drainage provided through a small separate wound below.

Evarts Graham<sup>14</sup> in 1933 successfully used this technique for a case of bronchial carcinoma, the first successful one-stage pneumonectomy with closure of the chest to be performed. An almost identical technique was used in three of the present cases, although only one lobe was removed at a time. This was necessary because of the somewhat ambiguous bronchograms available, the state of the upper lobe being undetermined in two of the cases until a second instillation of lipiodol was made after removal of the lower lobe. The condition of the patient after mobilisation of the lower lobe may also be such as to make this procedure sometimes advisable.

3. The remaining or two-stage method is that in which the pulmonary circulation is abolished by the application of mass ligatures either to the pedicle of the lung as a whole, or to the pedicles of the individual lobes, after their mobilisation. Tampons are arranged around the lung, and the wound closed temporarily after provision is made for irrigation with antiseptic solutions. The chest is reopened after a period of 10–12 days, the packs changed and the necrotic lung removed. Tardy separation of the sloughs may necessitate removal of the lung just beyond the ligatures, which will be extruded spontaneously shortly afterwards.

This technique should probably be used only when the mediastinum is known to be comparatively immobile and when a previous inflammatory process has so altered the pleura that its normal absorptive powers are likely to be greatly diminished. Its adoption in the presence of a virgin pleura seems to be little more than criminal, and in such cases the Sauerbruch and Alexander schools, both of whom favour the method, endeavour to promote adhesions between the visceral and parietal pleuræ at a preliminary operation—the former by using an extra-

pleural "plombe" and the latter by stroking the pleura with gauze.

Inadequately tied ligatures, or retraction of the hilar tissues within them, may lead to the development of moist rather than dry gangrene. If this is recognised by the occurrence of a profuse foul discharge, tighter ligatures are applied, but this detection

FIG. I.—Air embolism in the brain after lobectomy.

is not always possible until the patient is in extremis (Case 3). To obviate this danger rubber tubing is used by some instead of, or in addition to, the silk ligatures already mentioned. Alexander now recommends for this purpose an automatic tourniquet introduced by Carr. Confidence in the efficacy of the mass ligatures may justify immediate amputation of the lobes, and so minimise the amount of sloughing tissue. This step may be imperative when deterioration in the general condition after a difficult mobilisation contra-indicates the completion of an operation originally intended to be one-stage. Secondary hæmorrhage from the hilus, due to infection of the clot in the large vessels after or during separation of the sloughs, is not unknown, and appears to have been invariably fatal.

The two-stage method has many disadvantages: more than one severe operation is required; it involves the presence of a foul suppurating wound; and convalescence is delayed by a prolonged and serious illness extending not only between the stages, but often for some time afterwards, undoubtedly throwing a very great strain on the recuperative powers of the patient. Deformity is likely to be much greater because of the necessity of maintaining the wound open for a considerable period so that the sequestration process and its sequelæ may be to some extent under visual control; indeed, it may be necessary, as in two of the present series, to assist obliteration of the cavity by means of some type of thoracoplasty—this aid may also be necessary in other methods of pneumonectomy.

#### Difficulties and Complications

*Hæmorrhage* is an ever-present danger during a dissection in the vicinity of the pulmonary pedicle, and has usually proved rapidly, if not immediately, fatal. Meyer<sup>5</sup> and Lilienthal<sup>6</sup> have both reported their experiences in this connexion.

Premature or accidental release of the tourniquet is attended by serious hæmorrhage, but this accident need not necessarily prove fatal if suitable large

hæmostatic clamps are kept ready for such an eventuality. The situation may be retrieved, as it was in three cases of mine in which the accident occurred during lobectomy.

Serious loss of blood may occur from the numerous small vessels torn during the separation of dense adhesions, but this can usually be obviated by applying gauze pads to the raw area whenever possible whilst working in some other part of the chest. The loss may be so great as to require replenishment of the circulation by a transfusion of blood at, or even before, the termination of the operation.

The risk of secondary hæmorrhage, especially associated with separation of hilar sloughs, has already been alluded to.

*Shock*.—Retgression of the general condition during a difficult mobilisation is usually transient, but may compel cessation. Hence it is important to avoid lacerating the lung unless its removal is certain, otherwise serious septic complications will follow. Dr. Philip Ayre, the anæsthetist who is associated with me in this work, has lately in adult cases administered a spinal anæsthetic before inducing general anæsthesia. With this technique we have observed that the patients have been singularly little, if at all, disturbed by mobilisations of the most difficult and severe type.

*Air embolism* has not as yet been reported in connexion with this operation, but it has caused the death of two patients of mine on whom lobectomy was performed (see Fig. I.). There seems to be no reason why pneumonectomy should be completely immune from this accident and brief reference will therefore be made to it. In each case the upper lobe had been torn near the hilus. In the first this was being repaired when air was suddenly aspirated into a pulmonary vein because of a mishap to the anæsthetic apparatus, causing a sudden fall of the intrapulmonary air pressure. In the second patient a similar but smaller and not so accessible laceration was controlled merely by packing, and the fatal aspiration of air occurred about four hours later.

*Lung-root reflexes* were dealt with by O'Shaughnessy<sup>16</sup> in his Hunterian lecture last year. Certain

FIG. II.—Synchronous tracings (respiration, blood pressure, and pulse) showing effect of electrical stimulation (1, 2, and 3) deep in the interlobar fissure.

phenomena of this order have been observed in connexion with a variety of intrathoracic operations, but those experienced in Case 1 of the present series are worthy of mention. During manipulations in the interlobar fissure at the hilus and whenever the mass ligatures were tightened, there were curious bodily jerks, which appeared to be violent expiratory movements; in addition and simultaneously, the

auricles were seen to distend the pericardium, whilst the aorta apparently ceased beating. These occurred at least fifteen or twenty times. Somewhat similar phenomena were noticed recently in a lobectomy patient.

FIG. III.—Radiogram of cat's chest after pneumonectomy.

These disturbances can be reproduced with comparative ease in the cat by electrical stimulation applied deep in the interlobar fissure. Their nature may be studied with the help of simultaneous and synchronised tracings, recording changes in respiration, blood pressure, and pulse-rate (Fig. II.). This suggests the probability of these phenomena being reflexes of a nervous, probably vagal,

nature, and this is proved by their prevention when novocain is infiltrated into the tissues between the point of stimulation and the mediastinum. While dissecting the main pulmonary artery of a cat preparatory to pneumonectomy a similar bodily jerk was noticed; it coincided with immediate and permanent cessation of the heart beat and of respiration. Such a sudden fatality is rare, not only in the experimental animal, but fortunately in man. Sauerbruch, however, tells of a patient who died at the moment of application of a ligature to the pedicle of a lobe. As a precautionary measure the mediastinum near the hilus may be infiltrated with novocain. This, however, is usually only practicable

when the pleura is free; when pleural adhesions are a prominent feature, it is difficult and often impossible to make the necessary injection under visual control. This precautionary measure is therefore often withheld.

Delayed reflex phenomena, conveniently so-called, include a variety of conditions becoming manifest at a varying time after operation, such as tachycardia, dilatation of the right side of the heart, acute oedema of the contralateral lung, asthmatic wheezing, &c. Certain of these have been encountered in connexion with lobectomy rather than with pneumonectomy; but again there is no obvious reason why they should be regarded as unlikely in the latter.

FIG. V. (Case 1).—Bronchogram showing bronchiectasis of entire left lung.

Tachycardia is occasionally a prominent feature which may persist for some considerable time after operation. A rapid pulse was present for almost a fortnight in two of the patients in whom mass ligatures were employed; in the third, who died at the end of a week, it was present throughout the post-operative course. In certain of these cases the possibility of toxic absorption from the gangrenous lobe, due perhaps to shrinkage of the pedicle within the ligature, must be considered as a possible cause. Sometimes this acceleration of the pulse is progressive and fatal. In Case 5 the vagus nerve was found to have been damaged during the application of the tourniquet (Fig. XVII.). The patient, whose condition seemed satisfactory at the conclusion of the operation, had an increasingly and uncontrollably rapid pulse.

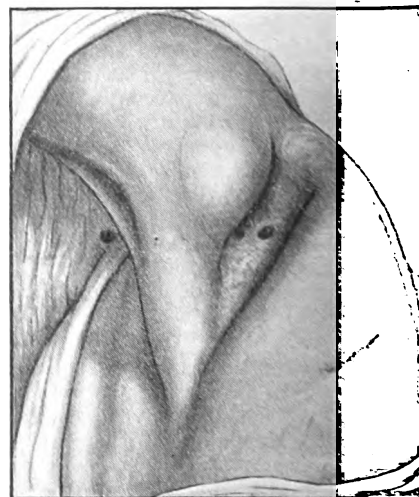

Dilatation of the right side of the heart may

A

B

C

FIG. IV Case 1).—Obliteration of the cavity after pneumonectomy.

possibly be associated with the increased mechanical strain thrown on the pulmonary circulation by these operations, but the compensatory abilities possessed by the circulatory system are well known. Both this and the experience that the onset of the complication may not be until many hours after the operation suggest the possibility that it may be essentially a reflex phenomenon of a delayed type. The same remarks apply to acute œdema of the remaining lung.

*Bronchial fistulæ* cause little disability when they open directly on to the surface of the chest wall. One such patient of mine even works in a coal-mine without any protective covering over a small fistula persisting after drainage of a pulmonary abscess. The danger of an aspiration pneumonia and of abscess formation in the other lung, due to these fistulæ, is increased if they open into a cavity between it and the parietes; it is still greater if these cavities are infected, and especially if they are inadequately drained. Reinhoff deliberately fractures the cartilage to overcome its spring-like action, which tends to reopen a bronchial wound. Others rely upon cauterising the bronchial mouth with silver nitrate prior to its closure by suture. The certain prevention of fistulæ is almost impossible, and the majority of patients develop one during some period of their convalescence. Admittedly some are so slight as to be recognisable—often unexpectedly—only with the aid of lipiodol.

*Tension pneumothorax* is a complication encountered much less often than would be expected despite the frequency with which the post-operative course in these cases is complicated by the presence of bronchial fistulæ. It is likely to arise only where drainage of the pleural cavity has either not been employed or has ceased because the tube has been obstructed or removed. Recognised by the sudden occurrence of severe respiratory distress it must be promptly relieved by the establishment of efficient drainage.

**Effects on the Chest**

The fate of a cavity from which the lung has been removed is a study of some interest. In the experimental animal the mediastinum moves towards the side from which the lung is removed (Fig. III.). To a less extent the chest wall falls in, and the diaphragm ascends, even when it is not paralysed, though naturally not to so high a level. A residual pneumothorax, roughly pyramidal in shape, with its base in

FIG. VI. (Case 1).—Necrotic lobes of the left lung removed 12 days after ligatures (below) had been tightly applied to the hilus. Half scale. (Specimen in Museum of Royal College of Surgeons of England.)

the pleural dome, persists between the axilla and the mediastinum. Exactly the same process happens in the human subject. This statement is supported by radiological evidence obtained in Case 4 (Fig. XII. a, b, and c on Plate), and also in Cases 1 and 2, where it was possible to watch the process through parietal wounds kept widely open (Fig. VI. A, B, and c). When there is no large or persistent bronchial fistula, and when the parietal wound has remained closed *ab initio*, the residual pneumothorax space is probably permanent. If, on the other hand, a major bronchial fistula persists with or without an associated external sinus, some form of thoracoplasty is required to obliterate the cavity (Fig. VII. A and B). Experience suggests that this should be carried out much sooner than was done in Cases 1 and 2, so that convalescence may be shortened and a more satisfactory final result obtained.

**The Cases**

**CASE 1**

M. V., a girl aged 13, referred by Dr. Horsley Drummond. Since the age of 5 she had suffered from recurrent attacks of "pneumonia," each of which was followed by profuse expectoration of foul sputum. In 1931, following such an attack, an empyema in connexion with the base of the left lung was drained at another hospital. She was admitted to the Royal Victoria Infirmary, Newcastle-

FIG. VII. (Case 1).—Radiograms after pneumonectomy, (A) partial obliteration of residual cavity, (B) after thoracoplasty.

upon-Tyne, in April, 1934, suffering from a pneumonic attack. Subsequent lipiodol examination demonstrated bronchiectasis of the entire left lung (Fig. V.). The sputum diminished and almost completely disappeared with general treatment, but pallor and clubbing of the fingers

FIG. VIII.—Case 1 one and a half years after pneumonectomy.

persisted. The chest wall was retracted on the left side and the sternum unduly prominent.

**Operation** (May 4th, 1934).—Anæsthesia was administered by Dr. W. J. Phillips. Preliminary basal narcosis with avertin (80 per cent. of the charted "Bayer" dose followed by intratracheal insufflation of oxygen, warmed) ether vapour, and a small quantity of nitrous oxide. A second intratracheal tube was also introduced to facilitate evacuation of pulmonary secretion. The patient was placed on her right side with a sandbag under the chest. A long incision was employed, extending from the spine behind to the sternum in front, and crossing the scapula about 3 cm. above its angle. The latissimus dorsi, &c., were divided in the line of the incision and the scapula retracted forwards and upwards. The 5th and 6th ribs were divided close to the spine, and their intercostal muscles divided throughout the length of the incision. These ribs were then widely separated with the help of a de Quervain retractor. The lung was completely adherent, but the two lobes were freed and mobilised with comparative ease. Two stout braided-silk ligatures (Pearsall No. 22) were tightly applied to the pedicle of each lobe, and the phrenic nerve was divided above the root of the lung to facilitate subsequent obliteration of the cavity. During manipulation of the hilus, and while the ligatures were being tightened, the curious bodily jerks were seen that have already been described and attributed to lung-root reflexes. Gauze tampons were wrapped round the lobes to prevent readhesion, and the wound was almost completely closed, except posteriorly for the tampons. Flavine was instilled daily.

The wound was reopened on the sixth day and the tampons changed. This was repeated on the eleventh day, but on this occasion the lobes were ablated with the help of a thermocautery (Fig. VI.), and the wound left widely open throughout its entire length (Fig. IV. A). Two or three days later the small remaining fragments of the pedicles in the ligatures sloughed off, and the cavity immediately began to diminish in size (Fig. IV. B). There was slight pyrexia, and the pulse-rate was about 120 for almost a fortnight after the sloughing lung was removed from the chest, but the thoracic cavity appeared clean

and the general condition steadily improved. For two or three days after the operation there was some degree of œdema of the opposite lung, evidenced by frothy expectoration, but this was easily controlled by atropine.

**Progress.**—Massage and appropriate exercises were carried out from an early stage in order to prevent the development of scoliosis. Having gained over a stone in weight, and with the general health greatly improved, the patient was allowed to return home on Sept. 30th. She attended as an out-patient at frequent intervals. The cavity has become greatly obliterated by flattening of the chest wall and elevation of the paralysed diaphragm until only the size of a walnut (Fig. IV. c). On its floor were two bronchial fistulae. Further spontaneous obliteration not having occurred, the patient was readmitted to hospital in October, 1935. Small portions of the upper five ribs were resected paravertebrally (Fig. VII.). This thoracoplasty has sufficed to diminish the cavity still further, and to such an extent that the upper bronchial fistula is now occluded, but the lower still persists in the floor of the depressed scar; it is hoped that applications of silver nitrate will suffice to obtain this closure. In any case it is unlikely that any other treatment will be adopted, the condition causing little or no disability.

The patient has remained free from cough and expectoration for more than eighteen months, clubbing of the nails has disappeared, and she leads a more or less normal life (Fig. VIII.).

#### CASE 2

H. V., a youth aged 18, referred by Prof. W. E. Hume. When he was 5 years old a small stone became impacted in the right bronchus and was not coughed up until two years later. Since then there was a constant and copious expectoration of foul sputum. He was in a sanatorium at one period, but tubercle bacilli were never detected in his sputum. Recently signs of toxic absorption became evident—clubbing of the fingers, night sweats, and loss of weight. He coughed up daily 8–10 oz. of foul sputum after admission to the Royal Victoria Infirmary. A lipiodol examination revealed the presence of such a gross degree of bronchiectasis that only scattered pools of lipiodol were seen in the right lung (Fig. XV. on Plate). The heart and trachea were much displaced to the right side. The right phrenic nerve was evulsed in September, 1934, as a preliminary to pulmonectomy. The sputum subsequently diminished in amount to 2 oz. a day.

**Operation** (Oct. 18th, 1934).—Anæsthesia similar to that in the first case was again given by Dr. Phillips. The incision was also the same; the right side of the

**chest was opened.** Despite radiological appearances the right lung was not adherent, except by a few bands at the apex and by a dense symphysis to the paralysed and elevated diaphragm. The lung was small and shrunken, and as it was difficult to demonstrate the interlobar

fissure, only one stout braided-silk ligature (Pearsall No. 22) was tightly applied to the whole hilus after mobilisation. No obvious reflex phenomena were observed, but the blood pressure at this stage having fallen to 30 mm. Hg (as recorded in the arm), the operation was rapidly terminated, as in the first case. The condition rapidly improved after the patient returned to bed, but a persistent pulmonary œdema, evidenced by frothy expectoration, developed, which required the repeated administration of atropine during the subsequent fortnight. The wound being opened, under light anæsthesia, on the seventh and again on the thirteenth day, the tampons were changed. It was hoped that the lung,

FIG. IX. (Case 2).—Lung after removal. About half scale.

which was now very much shrunken, would slough off, but as it failed to do so, it was removed with the galvano-cautery thirty days after the operation (Fig. IX.).

*Progress.*—The wound and the cavity diminished in size with amazing rapidity, the diaphragm rose steadily, and the mediastinum moved across in a striking manner.

The cavity itself, three months after the operation, was only about one-fifth or one-sixth of its original size, and at that time it appeared highly probable that a thoracoplasty would be required to obliterate it completely. There were three small bronchial fistulae, through which a certain amount of flavine-stained discharge was aspirated from the cavity, but this only amounted to approximately  $\frac{1}{2}$  oz.

FIG. X.—Case 2 after pneumonectomy.

a day. But further obliteration was very slow. The cavity, especially in its lower part, never seemed so singularly free from infection as in the previous case, and about four months after operation this was aggravated by an attack of scarlet fever. Subsequently this infection, which gave rise to occasional periods of hyperpyrexia, was found to originate in a localised area of osteitis in the rib immediately below the wound. This was removed and the attacks ceased.

In October, 1934, the patient, who had been allowed home for a while, was readmitted to hospital, and a thoracoplasty operation, similar to that employed at this juncture in Case 1, was performed. As a consequence the cavity is now represented by a deep chink, in the floor of which bronchial fistulae can be heard but not seen.

The general condition of this patient fluctuates considerably. There is still daily expectoration of approximately  $\frac{1}{2}$ –1 oz. of sputum, but it is not clear whether this originates in the wound or in the opposite lung, although no abnormal physical signs have been elicited in the latter (Fig. X.).

#### CASE 3

F. B., a boy aged 7, referred by Dr. J. R. Beal. Three years previously, whilst in a sanatorium for "chest trouble," he developed scarlet fever; under observation at tuberculosis clinic since because of occasional pain in chest and constant irritable cough accompanied by expectoration of foul sputum. A year later he was in hospital for thirteen weeks when râles were noticed in left lung; he was admitted to department of thoracic surgery, Sunderland Municipal Hospital, in March, 1935, because of a recent aggravation of symptoms and the onset of headaches, pain in the back, and vomiting. Coarse râles were audible throughout the left lung, and a few could also be heard posteriorly in the right lung; the heart was displaced to the left of the middle line. Bronchography demonstrated a gross degree of bronchiectasis involving the whole left lung.

*Operation* (April 15th, 1935).—Anæsthesia similar to that in the previous cases was administered by Dr. Philip Ayre. The left side of the chest was opened by a similar

incision through the fifth intercostal space, the ribs above and below being divided to give adequate access. Adhesions, which although numerous were not generalised, were separated with relative ease, and the two lobes of the lung were mobilised separately. Two stout braided-silk ligatures (Pearsall No. 22) were applied as tightly as possible to the pedicle of each lobe. Gauze tampons, soaked in flavine, were arranged around the lobes, and the wound closed as in the previous cases. The pulse-rate was 160 at the conclusion of the operation, but its volume was good.

*Progress.*—The general condition seemed satisfactory during the subsequent five days, the pulse-rate varied between 130 and 160, and the temperature between 97° and 101° F. It had been arranged to reopen the wound and change the tampons on the sixth day, but early that morning the patient collapsed. The pulse-rate did not increase markedly, but its character was much weaker; a greyish, slightly cyanosed appearance became apparent, and a foul odour from the wound was noticed.

Although apparently in extremis, it was decided to proceed with the intended toilet of the wound. On reopening, the chest and the lobes of the lung were in a state of moist gangrene, and the pleura was coated with lymph. Ligatures originally tight were no longer so, presumably because of the retraction of the tissues within them. The stinking lobes were cut away and slight bleeding from the pedicles was easily controlled by the application of new ligatures. Clean tampons were inserted, and the wound quietly closed. The patient, however, died a few minutes later.

Necropsy confirmed that death was due to intoxication from the necrotic lung already described. A probe was easily passed from the left auricle along the pulmonary veins on that side, there being no evidence of clotting.

#### CASE 4

L. G., a girl aged 10, referred by Dr. T. C. Hunter, had suffered from pneumonia on four occasions, the first being at the age of 8 months. She was in a sanatorium for observation for six months about two and a half years previously. She always had a very bad cough accompanied by expectoration of foul sputum. On admission to the Royal Victoria Infirmary she was stated to have "no life about her," a poor appetite, and to be losing weight. Bronchography indicated bronchiectasis limited to the left lung, but the extent of that organ's involvement was not clear, for, though sacculations were obvious in the lower lobe, their presence in the upper was uncertain (Fig. XI. a on Plate). The general condition improved considerably as the result of general treatment, the sputum rapidly diminished in amount and ultimately ceased. The patient was transferred to the Hospital for Sick Children for operation.

*First operation* (June 17th, 1935).—Anæsthesia similar to that with previous cases was administered by Dr. Ayre. The chest was opened through a posterolateral incision in the 7th interspace, additional access being obtained by removal of short pieces of the adherent ribs just behind their angles. Apart from a few adhesions at the base, the lung was free. Both lobes being normal in appearance, it was decided to remove the lower only at this juncture. The lobe having been mobilised, and its pedicle controlled by a tourniquet, it was removed. A series of hæmostatic sutures were used to close the vessels and bronchi in the pedicle, which was finally buried by a continuous suture in its own parenchyma. An airtight drainage-tube was inserted through a lower intercostal space, and the wound closed in layers.

A rapid and untoward recovery followed this operation. The upper lobe expanded so rapidly that the residual cavity became obliterated in about a fortnight, although the drainage-tube was retained for some time longer. The general condition also continued to improve. A further bronchogram, made on July 22nd, demonstrated the presence of a similar type of bronchiectasis in the upper lobe (Fig. XI. b on Plate).

*Second operation* (Sept. 14th, 1935).—Anæsthesia similar to that for the previous operation was again administered by Dr. Ayre. The chest was reopened through the same incision, but, in addition, about 5 in. of the 6th rib as

well as small posterior portions of the 5th and 7th ribs were removed. The upper lobe was only adherent below and to the diaphragm, which appeared to have ascended considerably since the previous operation. The removal of the upper lobe was carried out in the same way as that of the lower. The chest was closed as before, and an airtight drainage-tube provided below.

**Pathology.**—Both lobes of the lung removed in this case were occupied throughout by smooth-walled cysts communicating with, and indeed being an essential part of, the bronchial system. These appearances, taken in conjunction with the history, suggest the probability of this being a true example of congenital bronchiectasis (Fig. XIII.).

**Progress.**—Four days later the drainage-tube appeared to be blocked, and an X ray examination showed the presence of fluid in the cavity up to the level of the 2nd rib anteriorly (Fig. XII. a on Plate); the tube was changed, but without effect, presumably because a layer of lymph lay between it and the fluid. As the latter was not purulent, drainage was abandoned. A further X ray examination two days later showed that the fluid had disappeared (Fig. XII. b on Plate). The patient made an uninterrupted recovery without any elevation of temperature and was allowed up on the eighth day after the operation.

A bronchogram made on Oct. 19th demonstrates the division of the stem bronchus into two branches which abruptly terminate (Fig. XI. c on Plate); the heart is displaced completely into the left side of the chest, the diaphragm was elevated, and there was a pneumothorax, which has persisted. The patient has remained in good health and free from sputum (Fig. XIV.).

#### CASE 5

R. V., a boy aged 11, referred by Dr. Harbinson. Enjoyed good health until a year previously, when he became ill with pneumonia, subsequently complicated by an empyema for which drainage was performed. He remained in a chronic state of ill-health, constantly coughing up moderate quantities of offensive green sputum, and he was under observation for three weeks in a sanatorium during this period. On admission to the Hospital for Sick Children the sputum had diminished, and its daily production varied from 1-3 oz., but was still offensive. X ray exami-

FIG. XIII. (Case 4).—Upper and lower lobes after removal. Half scale. (Specimen in Museum of Royal College of Surgeons of England.)

nation of the lungs revealed a collapsed lower lobe on the left side, a subsequent bronchogram demonstrated dilatation of the bronchi in this lobe and possibly in the adjacent part of the upper lobe (Fig. XVI. a on Plate).

**First operation** (August 10th, 1935).—Anæsthesia similar to that in the other cases was administered by Dr. Ayre. An incision like that in the previous patient was employed. The upper lobe, which appeared healthy, was adherent to the parietes by fine, moderately firm adhesions. The lower lobe was purple, small, and collapsed, and it was mobilised and removed; the chest was closed as in the last case.

On the second day the temperature reached 100.5° F.—

the only post-operative elevation noted. Sputum production immediately increased to 4 oz. for three days and then varied between a trace and 3 oz. for the next few weeks. Convalescence was delayed by collapse of the upper lobe evidenced radiologically by tracheal displacement, although this was gradually corrected. A further bronchogram made on Sept. 29th confirmed the original suggestion that the lower part of the upper lobe was bronchiectatic (Fig. XVI. b). Because this was known to have been of a "wet" type after the first operation, removal of the lobe was determined upon.

**Second operation** (Oct. 5th, 1935).—Similar anæsthesia to that

for the previous cases was again administered by Dr. Ayre. The old incision was reopened and the upper lobe removed as in the previous case. The tourniquet at one stage, however, was readjusted because of the proximity of the vagus nerve.

At the conclusion of the operation the patient's condition seemed in every way satisfactory, the pulse-rate, for instance, being 90. About five hours later the boy became very ill. Marked pallor and restlessness developed and the pulse was weak and almost uncountable; restorative measures failed, and death occurred fourteen hours after operation. Approximately 18 oz. of fluid escaped by the tube; although this was heavily blood-stained

the blood was well diluted, and the boy's condition was not attributed to hæmorrhage.

The appearance of the viscera and vessels at necropsy were not such as would have been expected in a case of death from severe hæmorrhage. In point of fact, the only lesion discovered was that the vagus nerve had been damaged close to the root of the left lung. Prof.

FIG. XVII. (Case 5).—The damaged vagus nerve.

R. B. Green kindly dissected this and sketched the parts (Fig. XVII.). The vagus, just above the root of the left lung, was grooved transversely, and when the nerve at this level was teased a break in approximately half its fibres was demonstrated, a possible explanation of the fatal and uncontrollable tachycardia.

#### CASE 6

B. S., a boy aged 8, referred by Dr. J. Skinner, of Jarrow, and by Dr. Glen Davison. Since the age of 3 he had suffered from recurrent colds accompanied by coughing, expectoration of green sputum, pain in the chest, and night sweats. He had not suffered from

measles, scarlatina, or whooping-cough. On admission to the Hospital for Sick Children amphoric breathing and crepitations were heard in the lower part of the left lung, and 1-2 oz. of purulent sputum were expectorated daily. A bronchogram revealed the presence of bronchiectasis throughout the entire left lung (Fig. XVIII. *a* on Plate).

*First operation* (Feb. 12th, 1935).—Anæsthesia similar to that in the previous cases was administered by Dr. Phillips. A similar incision was also employed. Generalised easily separable adhesions were present and the lower lobe, which was purple and collapsed, was mobilised and removed; the chest was closed after the provision of syphon drainage. The external appearance of the upper lobe was comparatively normal.

Convalescence was delayed by a pneumonic infection in the opposite middle lobe and by a cervical herpes zoster. The wound healed well after a transient period of infection, but for a while 5-6 oz. of sputum were expectorated daily. The patient was discharged to a convalescent home on May 22nd. On returning home in October the general condition began to deteriorate and the sputum returned. Accordingly, removal of the upper lobe was decided upon after bronchography had demonstrated that bronchiectasis was still confined to that lobe (Fig. XVIII. *b* on Plate).

*Second operation* (Feb. 8th, 1936).—Similar anæsthesia to that for the first operation was administered on this occasion by Dr. Ayre. The chest was reopened by an intercostal incision at a slightly higher level than previously. The diaphragm was observed to be elevated although the phrenic nerve was intact, and the heart displaced markedly so as to occupy largely the space from which the lower lobe was previously removed. The upper lobe was removed in the same way as the lower lobe, and the chest closed with provision of syphon drainage.

An uneventful convalescence followed, the tube being removed on the seventh day and the patient allowed up, the wound being healed, on the tenth day after operation. He was then ready to go home. A bronchogram on March 28th demonstrated the division of the stem bronchus into two branches which abruptly terminate; the heart was displaced completely into the left side of the chest; the diaphragm was elevated, but the trachea appeared

FIG. XIX.—Case 6 after pneumonectomy.

to be centrally situated and to its left a small pneumothorax was visible (Fig. XVIII. *c* on Plate). The patient is now (April 2nd, 1936) in excellent health and free from sputum (Fig. XIX.).

#### Conclusion

The question of which technique should be employed in pneumonectomy is as difficult to answer as it is in lobectomy. In point of fact, both problems

are the same. When the direct operation is successful, it is brilliantly so; but its failures can be equally disastrous. Alexander has shown that the mortality of the two-stage operation is lower. My first three patients were treated in the former manner, following the precedent of the only two previously successful extirpations of the lung for bronchiectasis—those of Nissen and Haight. A different technique was adopted in the three later cases because an increasing experience with lobectomy suggested the likelihood of such being attended with success in these particular cases.

My present belief is that those cases in which there is no reason to suspect the presence of adhesions, or of induration around the hilus, and consequent increased friability of its vessels, the technique successfully practised by Reinhoff should be employed. Its scope would seem limited to certain cases of neoplastic or tuberculous disease; the advisability of its use for occasional cases of bronchiectasis is not yet known. In other instances an attempt should be made to amputate the lung through its pedicle, which may then be closed by suture, or, if the gravity of the patient's condition—usually after a mobilisation made difficult because of the density and distribution of adhesions—is such that cessation is necessary, the operation may be concluded by applying mass ligatures to the hilus.

Experience derived from such a small series of cases does not justify dogmatic assertions; it is merely offered as a contribution to the general stock of knowledge that is now rapidly accumulating concerning the surgery of the thorax.
